NOTE: This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice.
ABSTRACT

Background: Injection drug use-associated bacterial and fungal infections are increasingly common, and social contexts shape individuals' injecting practices and treatment experiences. We sought to synthesize qualitative studies of social-structural factors influencing incidence and treatment of injecting-related infections.

Methods: We searched PubMed, EMBASE, Scopus, CINAHL, and PsycINFO from January 1, 2000, to February 18, 2021. Informed by Rhodes’ “risk environment” framework, we performed thematic synthesis in three stages: (1) line-by-line coding; (2) organizing codes into descriptive themes, reflecting interpretations of study authors; (3) consolidating descriptive themes into conceptual categories to identify higher-order analytic themes.

Results: We screened 4,841 abstracts and included 26 qualitative studies on experiences of injecting-related bacterial and fungal infections. We identified six descriptive themes organized into two analytic themes. The first analytic theme, social production of risk, considered macro-environmental influences. Four descriptive themes highlighted pathways through which this occurs: (1) unregulated drug supply, leading to poor drug quality and solubility; (2) unsafe spaces, influenced by policing practices and insecure housing; (3) health care policies and practices, leading to negative experiences that discourage access to care; and (4) harm reduction programs, including structural barriers to effective service provision. The second analytic theme, practices of care among people who inject drugs, addresses protective strategies that people who inject drugs employ within infection risk environments. Associated descriptive themes were: (5) mutual care, including assisted-injecting and sharing sterile equipment; and (6) self-care, including vein health and self-treatment. Within constraining risk environments, some protective strategies for bacterial infections precipitated other health risks (e.g., HIV transmission).

Conclusions: Injecting-related bacterial and fungal infections are shaped by modifiable social-structural factors, including unregulated drug quality, criminalization, insufficient housing, limited harm reduction
services, and harmful health care practices. Enabling environment interventions that address these factors could further empower people who inject drugs to protect themselves and their community.
INTRODUCTION

Injection drug use-associated bacterial and fungal infections (e.g. skin and soft-tissue infections, endocarditis, epidural abscess) cause significant morbidity and mortality among people who inject drugs (PWID). The incidence of hospitalizations for severe injecting-related infections is increasing in Australia, Canada, the United Kingdom (UK), and the United States of America (USA).

Efforts to prevent injecting-related bacterial and fungal infections have focused on individual-level behavioural interventions, including education on hand-washing before drug preparation, skin-cleaning before injecting, and avoiding subcutaneous/intramuscular injecting. While individual-level interventions may be helpful for PWID who can adopt these practices, evaluations of these interventions have shown mixed results and the incidence of injecting-related infections continues to rise.

Risk for injecting-related bacterial and fungal infections likely reflects contributions of multiple factors external to PWID that enable and/or constrain their behaviour and influence health outcomes. Identifying, measuring, and ameliorating such social-structural factors has informed clinical and public health responses to other drug-related harms, including HIV, hepatitis C virus (HCV), and overdose. Understanding the influence of social context on health can broaden awareness of the causes of illness and inform more appropriate prevention and treatment interventions.

Objectives

To understand social-structural determinants of injecting-related bacterial and fungal infections and to identify opportunities for potential intervention, we aimed to: (1) systematically review qualitative studies on experiences of injecting-related infections, and (2) synthesize analyses of social-structural
factors influencing risk for injecting-related infections, their treatment, and subsequent health outcomes.

METHODS

Before conducting the search, we published our protocol and registered with PROSPERO (CRD42021231411). We modified our original protocol after our search and full-text review. Our protocol specified a “mixed studies review” of quantitative, qualitative, and mixed-methods studies. As we identified more and richer qualitative sources than anticipated, we decided to consider qualitative and quantitative data separately. Here, we report the qualitative systematic review and thematic synthesis. Quantitative results will be reported separately. This manuscript follows PRISMA guidelines and the ENTREQ statement on qualitative systematic reviews.

Conceptual model and framework

The “risk environment”, as developed by Rhodes and others, is a socio-ecological model describing how macro-environmental (e.g., criminalization; racism) and micro-environmental (e.g., local availability of needle and syringe programs) factors interplay to influence health practices and outcomes. The risk environment model encourages thinking about how people interact with and modify constraining environments (e.g., drug users’ unions organizing to repeal laws banning supervised consumption sites). Collins and colleagues recently extended the risk environment to incorporate intersectionality, considering how social-structural factors affect PWID differently depending on other social identities and their locations within power hierarchies, including race and gender.

Injecting-related bacterial and fungal infections occur through introducing bacteria or fungi into sterile tissues (often from commensal organisms living on the skin) and are precipitated by particulate matter.
that damages blood vessels, lymphatics, and heart valves. To conceptualise how the risk environment affects injecting-related infections at different times, we developed a framework (see Figure 1) illustrating a pathway from (a) drug acquisition (e.g. solubility of drugs); (b) drug preparation (e.g. using sterile water to dissolve drugs); (c) drug injection (e.g. accessing veins to avoid intramuscular injecting); (d) development of and care for superficial infections (e.g. self-treatment; primary care); (e) development of and care for severe infections (e.g. hospitalization); and (f) outcomes after infections (e.g. access to follow-up care). Not all PWID would progress through all stages; some PWID do not develop infections and many who develop infections never access treatment.

Eligibility criteria

A full description is in our published protocol. Briefly, we included articles in peer-reviewed journals reporting qualitative studies. We followed the Population, Exposures, Outcomes approach to eligibility criteria. The population was PWID (i.e., people injecting any psychoactive substance; excluding people only injecting performance-enhancing or gender-affirming hormones). Exposures were any social or environmental factors that may affect risk of infections, such as housing, service availability, or policing practices. Outcomes included incidence, treatment, or outcomes of injecting-related bacterial and fungal infections. Eligible studies were published in English or French between January 1, 2000, and February 18, 2021 (to capture contemporary research more likely to inform policy and clinical practice).

Information sources and search strategy

We searched PubMed, EMBASE, Scopus, CINAHL, and PsycINFO databases. We developed the search strategy in consultation with a librarian (see Supplementary Table S1 for full search strategy). We supplemented searches with backward and forward citation chaining and with other studies known to
the review team (which includes people with lived/past and living/current experience of injection drug use, researchers, and clinicians caring for PWID).

Data management and reference selection
We uploaded titles/abstracts into Covidence software, where they were automatically de-duplicated. Two reviewers (TDB and either MB, DL, EC, or IK) independently screened titles/abstracts, resolving discrepancies through consensus. We obtained full-text reports for sources that passed screening, and one reviewer (TDB) assessed full-text reports.

Quality assessment
We used the Mixed Methods Appraisal Tool (MMAT), which is a validated and commonly-used appraisal tool for mixed studies reviews. TDB and EC independently appraised each study, resolving discrepancies through discussion. For data synthesis, we included studies meeting both MMAT screening questions: “Are there clear research questions?” and “Do the collected data allow to address the research questions?”

Data synthesis
Following Thomas and Harden, thematic synthesis comprises three stages: (1) line-by-line open coding; (2) organizing codes into descriptive themes reflecting content of studies and study authors’ interpretations; (3) translating descriptive themes and associated codes across studies to generate analytic themes. Coding and generation of descriptive themes focuses on study authors’ analysis and interpretation because reviewers do not have full knowledge of the original study data.
First, TDB (physician and PhD student with qualitative methods training) familiarized himself with the included studies. Next, MB (researcher with lived/living experience of injecting-related infections and a drug policy activist) and TDB independently performed line-by-line coding on the same three purposefully selected, data rich sources. They compared and contrasted codes and revised them in an iterative, deductive-inductive process, informed by the risk environment model.

The whole review team met to provide feedback on these candidate codes: DL (public health specialist), EC and IK (medical students), DW (infectious diseases and addiction medicine physician), AK (infectious disease epidemiologist), and MH (health sociologist with lived experience of injection drug use). TDB coded the remaining papers over several rounds, including adding and revising new candidate codes after discussing with the team at meetings and through collaborative online writing.

TDB developed descriptive themes by comparing and contrasting codes across studies, seeking to organize codes into related social-structural categories and proposed them to the team for feedback. TDB then consolidated descriptive themes into conceptual categories to generate analytic themes that were finalized over several iterations and team meetings.

RESULTS

Following de-duplication, we screened 4,841 titles/abstracts and evaluated 631 full-text reports. After considering 16 additional reports identified outside the search, we identified 151 eligible studies (quantitative, qualitative, and mixed-methods) for our “mixed studies” review. Here, we report on the 26 studies with qualitative data and analysis (19 qualitative-only and seven mixed-methods). See Figure 2 for PRISMA diagram. All 26 qualitative studies met our quality criteria for inclusion (see Supplementary Table S2 for full MMAT results).
Study characteristics

See Table 1 for summaries of individual studies. The majority (n=20 studies) were conducted in North America. Qualitative data came from individual interviews (n=23), observation/ethnography (n=4), and focus groups (n=2). Studies included experiences of injecting-related skin and soft-tissue infections (n=22), endocarditis (n=7), bacteremia (n=3), and osteomyelitis (n=2). All 26 studies included bacterial infections, and only one study included fungal infections (candidemia and fungal ophthalmitis).

Thematic synthesis

Summary

We identified six descriptive themes organized into two analytic themes (see Figure 3).

The first analytic theme, social production of risk, considers how macro-environmental factors, including criminalization, poverty, structural stigma, mandated abstinence, and racism, shape risks for injecting-related infections. Four associated descriptive themes highlighted pathways through which this occurs:

1. unregulated drug supply, leading to poor drug quality and solubility; 2. unsafe spaces, influence by insecure housing and policing practices, and ameliorated by supervised consumption sites; 3. health care policies and practices, leading to experiences of discrimination and undertreated pain and withdrawal, which worsened infectious complications by alienating PWID and discouraging access to care; and 4. harm reduction programs, including structural barriers to effective service delivery.

The second analytic theme, practices of care among people who use drugs, addresses PWID expertise and agency in attempts to prevent and care for bacterial infections within constraining risk environments. Two associated descriptive themes categorized these practices as (5) mutual care,
including sharing sterile injecting equipment, assisting others with injecting into veins (rather than intramuscularly), and treating abscesses outside of medical settings; and (6) self-care, including promoting vein health and sourcing safer alternatives when sterile injecting equipment was unavailable. Within constraining risk environments, some of these mutual- and self-care protective strategies for bacterial infections precipitated other health risks, including HIV transmission or arterial injury.

Descriptive themes are detailed below, supplemented by quotations from study authors and participants (indicated in italics).

Unregulated drug supply

In five studies, authors presented perspectives from PWID who attributed infections to the quality of unregulated drugs, including adulterants, poor solubility, and bacterial contamination, especially through precipitating skin abscesses and vein sclerosis. Phillips and colleagues reported that PWID in Denver (USA) commonly linked their bacterial infections to poor drug quality:

“I think it’s the dope because... I’ll use a clean needle every time, and it still, it just depends on what they cut it with. You know, sometimes when you’re cooking it, it’s an okay color, and then the next time you’re doing it you’ve got all this shit floating up, and it’s all burnt around the sides.” (USA)

In two studies, authors analysed drivers of variation in the unregulated drug supply and associated infection risks. Mars and coauthors identified that PWID in Philadelphia (USA) could purchase only tared heroin (which is less soluble than powder heroin, and is associated with greater bacterial infection risk) due to regional demarcation of supply networks. Harris and colleagues highlighted London (England)
PWID accounts of changing drug quality over time which has impacted widespread overuse of citric acid, which is used to dissolve poorly soluble cutting agents or adulterants such as paracetamol and quinine.

Unsafe spaces

In eight studies,\textsuperscript{53,54,56,58–62} investigators attributed increased bacterial infection risk to suboptimal drug preparation and injecting techniques created by unsafe spaces, including when PWID lacked housing and when trying to avoid being seen by police when using outdoors.

In six of these studies,\textsuperscript{53,56,58,60,61,63} authors explored influences of being deprived of housing on infection risk. Lack of housing made it harder to prepare and inject drugs safely, including where there were no hygienic surfaces to prepare drugs,\textsuperscript{53,56,61} inadequate lighting to find veins (leading to “missed hits” and inadvertent subcutaneous injection),\textsuperscript{53} and no clean, running water to wash hands/skin or to dissolve drugs (leading PWID to use unhygienic water alternatives)\textsuperscript{56,58,60,61}:

“...there was no water actually and I had to use a bit of saliva. ...It worked, I still got my hit, but I also got the worst infection of my life, I nearly died ...Yeah, I was in hospital for nearly 3 months. Septicaemia.” (England)\textsuperscript{56}

In their studies of PWID with endocarditis, Bearnot and colleagues\textsuperscript{63,64} noted that deprived of housing interfered participants’ with care, including being ineligible for outpatient parenteral antimicrobial therapy and having no fixed address for follow-up clinic contacts.

In six studies\textsuperscript{53,54,56,58,59,62} authors analysed how criminalizing possession of drugs or injecting equipment (and associated police enforcement) increased risk for injecting-related infections. When lacking safer
indoor places to prepare and consume drugs, participants described engaging in riskier practices to avoid being seen by police. This included preparing and injecting drugs in unhygienic abandoned buildings, and compromising injecting preparation practice when hurrying and not using a filter, not using sterile water, and/or inadvertently injecting subcutaneously:

“I don’t even use cotton [a filter]... boom and I usually get it done. Like that. So, if the cops raid and... several times the cops have pulled over, come right up to me and I’ve already injected it in my arm before they hit me.” (USA)

In their ethnography, Bourgois and colleagues observed “greater and more antagonistic police surveillance” of African American PWID than of white PWID in San Francisco (USA), leading to racist, differential seizure of sterile syringes (obtained from legal needle and syringe programs). They observed police evict homeless encampments and confiscate possessions, causing PWID to miss medical appointments.

Three studies included analyses of how supervised consumption sites create safer spaces to reduce infection risks caused by lack of housing and criminalization, by facilitating individualized education on safer injecting techniques and access to wound/abscess care.

Health care policies and practices

In 13 studies, authors analysed why PWID delay or avoid medical care for injecting-related infections (often until infections had progressed and spread). Contributing factors were prior experiences of stigmatizing or discriminatory care (in 12 studies) and of untreated pain and withdrawal (in six studies). In several studies, PWID described both:
“I’m not trying to get drugs. I’m trying to get you to take your sharp scalpel, cut this fucking thing open, squeeze this shit out of me, and get me the fuck out of here. That’s the pain relief that I want you to give me...I can do heroin; your little 5mg Percocet ain’t doing nothing for me. But they automatically think when you come in, ‘I got an abscess. I’m hurting’, ‘Oh, you’re trying to get drugs’, this and that... it does prevent a lot of people from going.” (USA)53

Some negative experiences were driven by hospital policies. Harris61 explains how a London hospital policy mandates that urine drug screens be obtained before methadone can be dispensed, even if the dose is confirmed by pharmacies or treatment programs. This caused delays or missed dosages of methadone, and resulting experiences of opioid withdrawal led PWID to stay away:

“Mainly because how I have been treated at the hospitals, which is just like fucking dirt you’d find on your shoe... also being scared that I was going to be rough [sick] ...because if they didn’t [give] me Methadone, like someone’s said he [doctor] won’t do it unless he would have to, and if you don’t know your rights, but yeah, it was that that really scared me more than anything, was being sick [in withdrawal] in a hospital.” (England)61

Four studies60,61,67,69 included analyses of how delays in care due to negative experiences in health care settings had a disproportionate impact by race or gender. Assessing hospital care experiences in Vancouver (Canada), McNeil and colleagues67 described, “Many participants of Aboriginal ancestry further expressed that institutionalized racism reinforced the view among hospital staff that they were ‘drug-seeking’”. Three studies included descriptions of how PWID who were mothers were discouraged from accessing care for injecting-related infections, including feelings of shame at disclosing substance
use as a mother,\textsuperscript{60} and fear of child apprehension if their substance use was reported by health professionals.\textsuperscript{61,69}

In four studies,\textsuperscript{63,67,70,74} PWID described leaving hospital prematurely, before completing treatment for injecting-related infections. Explanations included leaving hospital in response to discrimination\textsuperscript{67,74} and because restrictions on their movements in hospital triggered post-traumatic stress.\textsuperscript{63} Two studies\textsuperscript{67,70} highlighted participants being involuntarily discharged from hospital because of drug use, despite ongoing medical need. Jafari and colleagues\textsuperscript{74} evaluated experiences with a care model intending to overcome these issues: clients at a residential, harm-reduction oriented program for people with severe injecting-related infections in Vancouver, Canada, described receiving less judgmental and stigmatizing care compared to their experience in mainstream hospitals.

Only one study specifically explored insufficient health insurance as a barrier to care.\textsuperscript{69} In other studies, authors explained that insurance is a barrier to health care for some PWID but their study participants had access to public health insurance (universally in Canada\textsuperscript{67}, and Medicaid in USA\textsuperscript{63,64}).

\textit{Harm reduction programs}

In four studies,\textsuperscript{52,55,56,71} authors analysed consequences of PWID having insufficient or nonpreferred drug preparation and injecting equipment distributed from harm reduction programs. In their study of experiences of skin and soft-tissue infections in Glasgow (Scotland), Dunleavy and colleagues\textsuperscript{52} report: “reasons for re-using [needles and syringes included having been] accidentally supplied with the wrong sized needles and preferring to re-use than use the wrong needle”. Three of these studies describe PWID lacking needed equipment and repurposing alcohol skin swabs distributed by harm reduction programs: to clean up blood after injecting,\textsuperscript{52,71} to filter visible particulate matter out of puddle water
when lacking access to sterile water, and burning swabs to obtain an adequate flame to heat the drug solution when lacking a sufficient lighter. In two studies, Harris and colleagues explored how legal/regulatory and funding restrictions on harm reduction programs limited the distribution of sterile water or single-use ascorbic acid packets.

In three studies, participants described structural barriers to needle and syringe programs that limited effectiveness. This included limited operating hours (e.g. closures on weekends) and restricted eligibility. McNeil and colleagues assessed consequences of PWID being unable to access sterile equipment in hospital, leading to reuse of contaminated equipment:

“[Nurses] don’t give rigs [syringes] to us. ...I think that they should. If not, we’re reusing our rigs or we’re having to risk getting kicked out for stealing them or people’ll be sharing them. ...I know one girl was using her same rig for days to the point where it was tearing and she was suffering every time she’d do her fix. She just didn’t have it in her to go and try and steal clean rigs.” (Canada)

Four further studies focused on places without local needle and syringe programs (in USA and Mexico), where PWID were also unable to purchase syringes at pharmacies due to refusal from pharmacists:

“I think that many [pharmacists] think that by prohibiting the sale of syringes that they are going to stop the usage of drugs...but what they are doing is wrong, because of that we have a harder time finding syringes. We need to use drugs in order to feel well, since when we are in need of a
fix we feel desperate enough that we don’t care and borrow one from a friend, since it’s a
desperate feeling...” (Mexico)\textsuperscript{76}

Paquette and colleagues\textsuperscript{68} explored how PWID would prefer having multiple access points for sterile
injecting equipment, including from both pharmacies and needle and syringe programs: “...one
participant indicated that using the [needle and syringe program] could out him as a PWID and expose
him to stigma from others because [needle and syringe programs] exclusively serve PWID. If PWID could
consistently access syringes at a pharmacy without fear of discrimination, some might prefer this option
because it offers a higher level of anonymity than [needle and syringe programs].\textsuperscript{68}

Two studies highlighted how suboptimal delivery of OAT after hospital discharge could increase risks for
recurrent infections, including involuntary discharge from OAT because of ongoing use,\textsuperscript{63} waiting
lists,\textsuperscript{63,64} and a lack of coordination:\textsuperscript{64}

“So I had methadone maintenance while I was in the hospital and I did not really have anything
lined up when I left [hospital], which, ultimately, could be one of the many reasons why I ended
up re-infecting my valve and back in the hospital.” (USA)\textsuperscript{64}

\textit{Mutual care}

Five studies\textsuperscript{52,53,60,62,71} included descriptions of PWID caring for each other to promote health and reduce
risks of infections. Within constraining risk environments, some of these protective strategies for
bacterial infections precipitated other health risks.
Mutual care practices include providing or receiving education from fellow PWID, sharing sterile needles or injecting equipment in settings of scarcity, and offering or receiving assistance with injecting to reduce infection risks:

“I have my boyfriend. I only hit with him, always with him. I do not like to do it with strangers or people to whom I do not know so well. ... My boyfriend helps me, because when I do it, it swells up.” (USA)

Once infections developed, study participants described providing or receiving wound care and abscess treatment or antibiotics from peers in order to avoid negative experiences with the health care system.

While navigating risk environments, protective strategies for bacterial infections could precipitate other health risks. For example, three studies assessed particular risks that women PWID face when relying on assisted injecting in the context of gendered power dynamics. In their study, Epele explored these trade-offs: “Abscesses and scars that are more frequent with muscle injection lead to further subordination within the hierarchies of their social networks, and deteriorate the women’s precarious strategies of income production. Although being injected by another increases the probability of HIV infection, it simultaneously prevents the visible physical damage that subjects these women to greater vulnerability.” Similarly, nonmedical abscess treatment or use of potentially inappropriate from nonmedical sources can lead to worsening infections, but PWID described employing these strategies to avoid negative experiences in health care settings.
Twelve studies included analyses of participants’ practices to prevent and treat bacterial infections. These included practices to promote vein and skin care, including staying hydrated, rotating injecting sites, taking extra time to access veins, asking for help to access veins, and self-treating superficial abscesses (e.g., incision and drainage; nonmedical sources of antibiotics) before they progressed.

“Little things like drink a lot of liquids, make sure you sleep every night. Make sure you get enough sleep, drink liquids, eat regularly.” (USA)

In three of these studies, authors highlighted actions to mitigate the risks of poor-quality drugs or injecting equipment, including sharpening the tips of used needle tips to avoid vein damage (when unable to access new needles), sourcing safer water by asking passers-by for bottled water, and using ascorbic acid (which is safer than citric acid or lemon juice) when preparing heroin.

In five studies, participants also described changing their drug use practices after experiencing an infection, to avoid another one. This included applying new learnings on safer injecting techniques, switching from injecting to smoking, getting wounds assessed by a nurse, using the minimum required acidifier to dissolve drugs, and seeking addiction treatment to reduce or abstain from injection use.

Three studies included descriptions of self-care practices of PWID to avoid discrimination and structural stigma. This included injecting in central veins at hidden sites to avoid scars at more visible peripheral sites, and using in unhygienic abandoned buildings to avoid being seen.
Some of these protective self-care strategies employed within constraining risk environments also led to other potential health risks. For example, injecting in central veins in the groin to avoid discrimination from visible scars increases risks of thrombosis and arterial injury, and likely increase risks for bacterial infections (as the groin has a higher burden of bacterial colonisation). Considering unintended harms of inappropriate self-treatment of bacterial infections, Gilbert and colleagues\textsuperscript{71} write: “There are certainly risks conferred by the self-care practices that PWID are forced to resort to. However, these risks are not taken lightly by PWID; they are weighed against the risk of inaction and worsening infections, which is well known in these communities.”

\textbf{DISCUSSION}

We reviewed qualitative studies on experiences of injection drug use-associated bacterial and fungal infections, and used thematic synthesis to identify social-structural factors influencing risk for these infections. These include poor quality of unregulated drugs, insufficient housing, policing practices, limited harm reduction services, and harmful health care practices. These are shaped by macro-environmental factors including structural stigma, criminalization, government austerity, and racism. We also identified ways in which PWID care for themselves and others to prevent and treat injecting-related infections, including by sharing sterile equipment and treating infections outside of medical settings. Within constraining risk environments, PWID face trade-offs and some of these protective strategies precipitated other health risks (e.g. in some circumstances of assisted-injecting). Enabling environment interventions that address these social-structural factors could further empower people who inject drugs to protect themselves and their community. While the importance of education on safer injecting technique came up in several studies,\textsuperscript{52,53,55,66,76} our findings suggest that individual-level behavioural interventions alone are likely insufficient to reduce risk.
Several social-structural determinants of bacterial and fungal infections (as well as practices of mutual- and self-care\(^{35,78}\)) that we identified are consistent with prior studies examining risk for HIV and HCV among PWID.\(^{27,29,42,79}\) Insecure housing, hurrying injections to avoid police, insufficient harm reduction services, and laws restricting sterile injecting equipment are known to contribute to HCV\(^{79}\) and HIV\(^{27}\) risks. Stigmatizing and discriminatory health care experiences similarly discourage HCV and HIV treatment access and exacerbate health inequities.\(^{30,80}\) Compared to the literature on HIV and HCV among PWID,\(^{81,82}\) we identified relatively little published research considering intersectionality and risk for injecting-related bacterial or fungal infections.\(^{42}\) A qualitative study by Hrycko and colleagues published after we conducted our search identified several social-structural factors contributing to risk for severe bacterial infections, including availability and use of drugs (e.g. fentanyl, stimulants) associated with a shorter duration of effect and more frequent injecting, and lack of access to sterile water.\(^{83}\)

A key motivation for our review was to identify potential opportunities to reduce risks for injecting-related bacterial and fungal infections. Many social-structural factors that we identified are modifiable, and some have already been resolved or ameliorated in some places. These include PWID organizing to access better quality, regulated drugs including via injectable OAT (with liquid formulations of diacetylmorphine, hydromorphone, or fentanyl), and through “safe supply” prescribing programs or compassion clubs.\(^{84–86}\) Injectable OAT is associated with low risk for bacterial infections even when injected intramuscularly, since sterile, liquid formulations of drugs are provided in a hygienic and safe environment.\(^{87}\) Social and supportive housing (including Housing First) can help PWID access and maintain housing; some models combine housing with injectable OAT, safe supply, and/or supervised consumption sites.\(^{88–90}\) In some jurisdictions PWID and their allies have successfully advocated for decriminalization of drug/syringe possession and for laws enabling supervised consumption sites.\(^{91}\)
Several initiatives have improved health care experiences for PWID with injecting-related infections, including incorporating harm reduction and cultural safety principles, specialized addiction medicine consultation services, needle and syringe programs, and supervised consumption sites into hospital care. Policy changes are needed at many hospitals to facilitate these initiatives.

Our study has three key limitations. First, our review only included studies describing experiences of injecting-related infections and we did not include all studies investigating determinants of risky injecting practices (e.g. subcutaneous injecting; reuse of contaminated equipment) unless explicitly connected to infections. Second, we did not include gray literature that might have discussed further social-structural factors beyond those we identified in peer-reviewed papers. Third, some commentators have argued that qualitative evidence syntheses decontextualize the nuanced findings of qualitative studies (conducted in different settings, with different methods) and try to consolidate knowledge that is not generalizable. We undertook this approach to understand how social and structural factors shape risks for injecting-related infections in ways that may be impossible to assess with quantitative research.

Conclusions

Injecting-related bacterial and fungal infections are shaped by modifiable social-structural factors, including unregulated drug quality, criminalization, insufficient housing, limited harm reduction services, and harmful health care practices. Enabling environment interventions that address these factors could further empower people who inject drugs to protect themselves and their community.
ACKNOWLEDGMENTS

We thank Louise Gillis (Research Data Librarian at Dalhousie University) for helpful feedback and assistance with our search strategy. We thank Drs. Lindsay Wallace (Cambridge University), Ashish Thakrar (University of Pennsylvania), and Paul Christine (Boston Medical Center) for helpful comments on earlier manuscript drafts.

We acknowledge that TDB, MB, EC, and IK live and work in Mi’kma’ki, the ancestral and unceded territory of the Mi’kmaq, and DW lives and works in unsurrendered and unceded territory and traditional lands of Wolastoqiyik. This territory is covered by the Treaties of Peace and Friendship which the Mi’kmaq and Wolastoqiyik Peoples first signed with the British Crown in 1725. The treaties did not deal with surrender of lands and resources but in fact recognized Mi’kmaq and Wolastoqiyik title and established the rules for what was to be an ongoing relationship between nations. We are Treaty people.

FUNDING

TDB is supported by the Dalhousie University Internal Medicine Research Foundation Fellowship, a Canadian Institutes of Health Research Fellowship (CIHR-FRN# 171259), and through the Research in Addiction Medicine Scholars Program (National Institutes of Health/ National Institute on Drug Abuse; R25DA033211). For part of this work, he was supported by the Killam Postgraduate Scholarship, Ross Stewart Smith Memorial Fellowship in Medical Research, and Clinician Investigator Programme Graduate Stipend (all from Dalhousie University Faculty of Medicine). MB, EC, and IK were supported in this work via the Ross Stewart Smith Memorial Fellowship in Medical Research (PI: TDB). DL was funded by a National Institute of Health Research Doctoral Research Fellowship (DRF-2018–11-ST2-016). MH
was funded by a National Institute of Health Research Career Development Fellowship (CDF-2016-09-014).

The views expressed are those of the author(s) and not necessarily those of the NHS, the NIHR or the Department of Health and Social Care. These funders had no role in the conduct or reporting of the research.

DECLARATIONS OF COMPETING INTEREST

MB reports personal fees from AbbVie, a pharmaceutical research and development company, and grants and personal fees from Gilead Sciences, a research-based biopharmaceutical company, outside of the submitted work. The other authors report no competing interests.

PWID with endocarditis avoid health care because of stigmatizing and discriminatory experiences. The experience of endocarditis motivated some participants to enter addiction treatment and pursue abstinence.

Stigma associated with skin and soft-tissue infections motivated some participants to try to reduce risks, including use of sterile equipment and safer injecting techniques. No participants had learned about infections and associated risks from harm reduction programs. Social and environmental factors contributing to infection risk included insufficient access to sterile injecting equipment, caustic adulterants in the local drug supply, and a lack of hygienic spaces to prepare and consume drugs.

Some women who inject drugs rely on injecting assistance from others to avoid intramuscular injection and
Gilbert 2019\textsuperscript{71} USA

Secondary analysis of interview data from Summers 2018\textsuperscript{72}

Thematic analysis

Same sample as qualitative sample in Summers 2018\textsuperscript{72}

12 clients of a syringe services program in Boston (n=6) and Sacramento (n=6)

25% women; median 46 years; housing status not reported

Experience of skin and soft-tissue infections

Health belief model (HBM) of health-seeking behaviors

Conceptual Model of Medical Care Avoidance

PWID had good knowledge about skin infections and avoided formal health care due to traumatic experiences, discrimination, and unnecessarily painful procedures. Participants described multiple strategies for prevention and treatment of injecting-related infections including hydration, topical applications, non-prescribed antibiotics, and incision and drainage by non-medical providers.

Harris RE 2018\textsuperscript{a}\textsuperscript{53} USA

Individual interviews

Analysis approach not specified

19 clients of a syringe services program in Philadelphia

53% women; median age 39 [27-59 years]; housing status not reported

Experiences of skin and soft-tissue infections

None specified

PWID described good knowledge about risks of injecting-related skin infections, but were prevented from using hygienic techniques as they lacked of safe places to use drugs. Participants therefore injected abandoned buildings or outdoors, with inadequate lighting, or fear of assault.

<tbody>
<tr>
<td>Harris RE 2018b</td>
<td>USA</td>
<td>Individual interviews, Thematic analysis</td>
<td>Same sample as Harris RE 2018a. 19 clients of a syringe services program in Philadelphia. 53% women; median 39 years; housing status not reported</td>
<td>Perceptions of safe injecting facilities. Rhodes’ risk environment. Participants described commonly being forced to inject in public spaces, which led them to rush and inject intramuscularly or subcutaneously for fear of assault or arrest. Participants supported the idea of a supervised injection site to reduce these risks and inject more safely. Participants with stable housing preferred to inject at home and described that this reduced risks of injecting-related infections due to less fear of assault or arrest, adequate light and heat, running water, and space to store sterile injecting equipment.</td>
</tr>
<tr>
<td>Harris M 2019</td>
<td>England</td>
<td>Mixed methods, Individual interviews, Constructivist grounded theory</td>
<td>31 PWID recruited through drug treatment services, homeless hostels, and day centres</td>
<td>Use of acidifiers. Rhodes’ risk environment. Excessive acidifier use in drug preparation for injection is common and contributes to venous damage and risk for bacterial infections. Some participants determined the amount of acidifier to use through expert practice (e.g., visual cue of solution).</td>
</tr>
</tbody>
</table>

Housing status not reported, or arrest, leading to drug contamination and intramuscular injection. Participants tended to avoid medical care for injecting-related infections due to prior negative healthcare experiences, including stigma and inadequate treatment of withdrawal and pain. Some participants described self-treatment of infections, including increased drug use for pain control and performing incision and drainage on themselves.
| Harris M 2020a\textsuperscript{61} | England | Individual interviews | 36 PWID, recruited through specialist drug services, homeless hostels, and day centres across London, UK. 12% women; mean 46 years; 64% unstably housed in past 12 months. | Experiences of injecting-related injuries and infections | Everyday violence  
Structural violence  
Cultural safety | Engagement with the medical system (including for injecting-related infections) is a “last resort”; often participants delayed as long as possible to the point that they were critically ill. Participants avoided or delayed accessing medical care for their own protection, including because of experiences of discrimination and undertreated withdrawal and pain; one participant specifically worried of stigma against mothers who use drugs and associated risks of child apprehension. Participants described leaving hospital prematurely and self-treating wounds instead. |

| Harris M 2020b\textsuperscript{56} | England | Mixed methods | 32 PWID, recruited through specialist drug services, homeless hostels, and day centres | Water for preparing injecting solutions | Rhodes’ risk environment | Environmental constraints to sourcing sterile water for injection preparation (and staying hydrated to promote vein health) include lack of housing, public washrooms, or sterile water from harm reduction programs. When injecting in public places, fear of arrest |
would lead people to rush their preparation and inject as fast as possible. As a result, participants described using more readily available but unsafe alternative water sources including puddle water, toilet cistern water, whisky, cola soda, and saliva to prepare injections, which were associated with bacterial infections. Participants described several strategies to promote health and safety despite these environmental constraints, including filtering water through alcohol swabs or asking passers-by for bottled water.

Participants described past experiences of leaving hospital before completion of their medical treatment because of judgmental and stigmatizing care. Clients with severe injecting-related infections who were being cared for at a harm reduction-oriented medical respite describe receiving less judgmental and stigmatizing care compared to their experience in acute care hospitals.

Participants accessing the supervised injection site found it a uniquely valuable setting to receive education on (and to implement) safer drug preparation and injecting techniques, which they attributed to reduced frequency of abscesses. When they did not have access to the supervised

<td>Comparing perspectives of PWID in two different heroin markets.</td>
<td>In San Francisco, where heroin was mostly in “tar” form, participants attributed abscesses to the characteristics of tar heroin including poor solubility. In Philadelphia, where more-soluble power heroin as well as cocaine was widely available, participants attributed abscesses to missing veins (i.e., injecting subcutaneously or intramuscularly) and when injecting cocaine. The authors attribute regional differences in abscess risk to geopolitical forces that have segmented the U.S. heroin market.</td>

<td>45% women; median age 26; housing status not reported</td>
<td>Scarcity of sterile needle and syringes led PWID to share and re-use syringes. Factors limiting sterile syringe access included pharmacies refusing to sell them or requiring an ID, and a state “drug paraphernalia” law that criminalizes possession of syringes. Participants would travel out-of-state to pharmacies that would sell syringes, but police were aware of this and would stop and search cars with out-of-state license plates after visiting a pharmacy. One participant obtained sterile syringes from a family member with diabetes and distributed them to people in her community who inject drugs.</td>
