New FY.4 Omicron lineage in Kilifi, Kenya

Key Words
FY.4, SARS-CoV-2, Omicron, Kilifi, Kenya

Abstract
We report a newly emerged SARS-CoV-2 Omicron lineage, named FY.4, that has two unique mutations; spike:Y451H and ORF3a:P42L. FY.4 emergence has coincided with increased SARS-CoV-2 cases in coastal Kenya, April-May 2023. We demonstrate the value of continued SARS-CoV-2 genomic surveillance in the post-acute pandemic era in understanding new COVID-19 outbreaks.

Main Text
To date over 340,000 test-confirmed COVID-19 cases and 5,688 COVID-19-related deaths have been reported in Kenya[1]. Sero-surveillance reports indicated a high seropositivity in rural and urban populations despite low vaccine uptake (27.9% of the adult population vaccinated with at least one dose)[2]. Specifically, by August 2022, 69%-81% of rural (Kilifi and Siaya) and 89%-95% of urban (Nairobi and Kisumu) adult population in Kenya had anti-Spike glycoprotein IgG antibodies (not published).

Genomic surveillance has been critical in informing origins of new waves, evolution, and geographical spread patterns of SARS-CoV-2. By June 2023, seven distinct waves of SARS-COV-2 infections were observed in Kenya[1][3]. The last three were dominated by Omicron sub-variants: BA.1-like, BA.5-like and BQ-like, respectively. These sub-variants were associated with increase in SARS-CoV-2 cases due to possession of mutations that conferred pre-existing immunity escape and transmission advantage[4].
In coastal Kenya, the KEMRI-Wellcome Trust Research Programme (KWTRP) has been conducting SARS-CoV-2 genomic surveillance across five health facilities (HF) within the Kilifi Health and Demographic Surveillance System (KHDSS)[5]. Samples are collected weekly from individuals of all ages presenting with acute respiratory illness (ARI) for screening. SARS-CoV-2 testing and sequencing is performed on: (i) samples collected from persons seeking medical attention from selected HF within the KHDSS and (ii) positive SARS-CoV-2 samples from collaborating public and private HF across Kenya.

Beginning late March, SARS-CoV-2 positivity rate in the HF increased from a background level of 1.2% in the week commencing 27th March, and peaked at 42.9%, in the week commencing 24th April (Figure, panel A). However, the positivity rate dropped in the first week of May to 23.5% and ranged between 5.0%-7.7% over the next three weeks. Between January and May 2023, 76 samples were sequenced and assigned into three lineages; BQ.1.1(n=1), BA.1.1(n=2) and FY.4(n=73). The increase in the positivity rate starting late March coincided with detection of a new Omicron lineage namely, FY.4 (Figure, panel B). In Kenya, the FY.4 lineage was first observed in Lamu County(n=4) on the 10th March 2023 (Figure panel A). By 27th May 2023, this new FY.4 lineage was further detected in four additional counties including the coastal counties of Kwale(n=2), and Mombasa(n=2), and central counties of Kiambu(n=5) and Nairobi(n=4). In Kilifi, FY.4 variants were first detected from samples collected on 27th March 2023 and by April and May they became the predominant lineage representing 97% of all the detected lineages. Kenya is the first country to report the circulation of FY.4 lineage and has so far (based on GISAID data accessed on 30th June 2023) been detected in eleven other countries; Austria, Germany, Italy, Sweden, Canada, France, China, Australia, Spain, United Kingdom and United States[6].

Participants who had the FY.4 variant presented to the KHDSS HF mainly with cough (98%), fever (78%) and nasal discharge (74%) while 7% presented with difficulties in
breathing (Table). Only 13 (16%) participants had received at least one dose of the
AstraZeneca vaccine. However, a sero-surveillance study (February – June 2022) show that
67% of the unvaccinated KHDSS residents have anti-SARS-CoV-2 IgG antibodies showing
that a high proportion of this population may have naturally acquired immunity from
previous exposure[7].

Relative to other Omicron lineages, the FY.4 has two additional amino acid mutations;
in the spike(Y451H) and ORF3a(P42L) genes. The potential phenotypic impact of the Y451H
change remains unknown. Previous studies have shown that spike amino acid change in the
receptor binding domain (RBD) near the Y451H, such as L452R increases virus infectivity
and fusogenicity by enhancing spike stability and cleavage[8]. However, mutations within the
ORF3a CD8$^+$ T cell epitopes have been reported to cause complete loss of recognition in the
ancestral lineages and Alpha VOC[9].

We applied a Bayesian hierarchical model[10] to estimate the growth rate of the FY.4-
like lineage in Kenya. These estimates serve as warning system for lineages showing
consistent increase in frequency for at least two consecutive weeks in Kenya and/or other
countries. Growth rate estimates on Kenyan data was compared to data from Germany and
USA, as these were the only countries with reported FY.4 cases in at least two consecutive
weeks as of the last weeks of May (Figure, panel C). The model has warned of a high level of
concern in Kenya as from week of March 26 towards May, suggesting continued increase in
cases attributed to the FY.4 lineage.

In summary, surveillance of SARS-CoV-2 in Kenya has detected the emergence of a
new Omicron lineage with unique spike and ORF3a gene mutations. Detection of FY.4
lineage coincided with increase in SARS-CoV-2 cases in Kilifi and has also been detected in
other parts of the country. Growth estimates suggests potential for continued increase in
geographical spread of FY.4. Further analysis on the immunological impacts of the observed mutations and any transmission advantage arising are ongoing.

Acknowledgement

We thank the laboratories, hospitals and organisations that shared specimens for sequencing at KWTRP and the submitting laboratories where genetic sequence data were generated and shared via the GISAID Initiative, on which this research is based. Submitting and the Originating laboratories of the GISAID data used in this study are listed in the gisaid_supplemental_table_epi_set_230627qs.pdf

Funding

This work was supported by (i) New Variant Assessment Programme (NVAP), The New Variant Assessment Platform (NVAP) is a UK Health Security Agency programme funded by the UK Department of Health and Social Care (DHSC) as a global initiative to strengthen genomic surveillance for pandemic preparedness and response to emerging and priority infectious diseases, National Institute for Health and Care Research (NIHR) (project references 17/63/82 and 16/136/33) using UK Aid from the UK Government to support global health research, The UK Foreign, Commonwealth and Development Office (FCDO) and (ii) The Wellcome, UK (grant# 220985/Z/20/Z and 226002/A/22/Z). The views expressed in this publication are those of the author(s) and not necessarily those of NIHR, the Department of Health and Social Care, or the Foreign Commonwealth and Development Office, the Africa-CDC, WHO-Afro, ASLM.

Data Availability

Genome sequences generates in this study are available on GISAID. Generated genomes are listed in the gisaid_supplemental_table_epi_set_230627zw.pdf. The, the dataset
and analysis scripts used are available in Havard Dataverse at

https://doi.org/10.7910/DVN/ZMGR5P

Conflict of Interest

Authors declare no conflict of interest.

Ethical Statement

The whole genome sequencing study protocol was reviewed and approved by the

Scientific and Ethics Review Committee (SERU) residing at the Kenya Medical Research Institute (KEMRI) headquarters in Nairobi (SERU # 4035).
