Abstract: Preterm infants (<34 weeks gestation) experience high rates of morbidity and mortality before hospital discharge. Genetic disorders substantially contribute to morbidity and mortality in related populations. The prevalence and clinical impact of genetic disorders is unknown in this population. We sought to determine the prevalence of commonly diagnosed genetic disorders in preterm infants, and to determine the association of disorders with morbidity and mortality. This was a retrospective multicenter cohort study of infants born from 23 to 33 weeks gestation between 2000 and 2020. Genetic disorders were abstracted from diagnoses present in electronic health records. We excluded infants transferred from or to other health care facilities prior to discharge or death when analyzing clinical outcomes. We determined the adjusted odds of pre-discharge morbidity or mortality after adjusting for known risk factors. Of 409,704 infants, 5838 (1.4%) had genetic disorders. Infants with trisomy 13, 18, 21, or cystic fibrosis had greater adjusted odds of severe morbidity or mortality. Of the 17,427 infants who died, 566 (3.2%) had genetic disorders. Of the 65,968 infants with a severe morbidity, 1319 (2.0%) had genetic disorders. Our work demonstrates that genetic disorders are prevalent in preterm infants, especially those with life-threatening morbidities. Clinicians should consider genetic testing for preterm infants with severe morbidity and maintain a higher index of suspicion for life-threatening morbidities in preterm infants with genetic disorders. Prospective genomic research is needed to clarify the prevalence of genetic disorders in this population, and the contribution of genetic disorders to preterm birth and subsequent morbidity and mortality.

NOTE: This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice.
Introduction

Preterm infants, particularly those born before 34 weeks’ gestation, experience high rates of severe morbidity and mortality prior to discharge.\textsuperscript{1-3} Genetic disorders have been shown to strongly contribute to morbidity and mortality in related populations including full-term infants and children with critical illness.\textsuperscript{4-7} Genetic disorders are particularly prevalent in stillbirth and fetal disorders.\textsuperscript{8-10} Despite this, there are limited descriptions of the prevalence of genetic disorders in preterm infants. Boghossian et al. described the prevalence, morbidity, and mortality of very low birthweight infants with common aneuploidies.\textsuperscript{11,12} However, no studies to our knowledge have provided a comprehensive description of genetic disorders diagnosed in this population. We therefore sought to achieve the following objectives: 1) determine the prevalence of commonly diagnosed genetic disorders in preterm infants, and 2) determine the association of these genetic disorders with severe morbidity and mortality in preterm infants.

We recently utilized the Pediatrix Clinical Data Warehouse (CDW) in related studies, to investigate the association of congenital renal anomalies with genetic disorders in preterm infants.\textsuperscript{13} CDW contains detailed records of 20% of preterm infants born in the United States. Given this utility and broad representation, we sought to employ a similar strategy in this study.

Methods

This study was approved by the institutional review board of Columbia University. This report followed the guidelines for cohort studies as outlined by Strengthening the Reporting of
Observational Studies in Epidemiology (STROBE). This was a retrospective study using the CDW multicenter cohort of infants born prior from 23 to 34 weeks’ gestation.

Prevalence of commonly diagnosed genetic disorders in preterm infants.

Multiple genetic disorders, including common aneuploidies, are associated with fetal growth restriction. Therefore, we used a gestational age-based cutoff rather than weight-based. We extracted records from 409,704 infants discharged from 2000 to 2020. Data from NICU admission to discharge were collected, including clinician-noted diagnosis of genetic disorders. This cohort did not undergo prospective, genome-wide genetic testing. Diagnoses were limited to those made during standard care.

Association of commonly diagnosed genetic disorders with severe morbidity and mortality in preterm infants.

We collected infant characteristics (gestational age, birth weight categorization by Fenton criteria, maternal self-identified race, sex, mode of delivery, exposure to antenatal betamethasone, intubation in the first 72 hours of life, year of discharge, and the presence of congenital anomalies) and data regarding clinical outcomes (diagnoses of severe co-morbidities, mortality, and disposition). Severe morbidities were defined as the following: acute kidney injury (AKI) defined by the diagnosis of oliguria or anuria (ICD-9 788.5 or ICD-10: R34); severe intracranial hemorrhage (ICH) defined as grade III or IV intraventricular hemorrhage by Papile criteria or cystic periventricular leukomalacia; medically or surgically treated necrotizing enterocolitis (NEC); severe bronchopulmonary dysplasia (BPD) defined as invasive
mechanical ventilation at 36 weeks’ postmenstrual age; severe retinopathy of prematurity (ROP) defined as need for any medical or surgical intervention; culture-positive sepsis defined by any positive blood or urine culture; or shock defined as administration of any vasopressor or inotrope.

We used logistic regression to model the relationship between genetic disorders and severe morbidity or mortality. The following were covariates: year of discharge, gestational age, birth weight (here as a Z-score normalized to gestational age and sex to account for continuous rather than categorical effects), sex, maternal race, mode of delivery, intubation in the first 72 hours of life, presence of a congenital anomaly, and exposure to antenatal betamethasone. We excluded infants with missing covariate data, as well as those transferred after birth (often because of complex illness) and infants transferred prior to discharge (in which the clinical outcome is unknown) to limit ascertainment biases. We determined crude and adjusted odds ratios (OR) after controlling for these covariates. OR were reported with 99.97% confidence intervals (determined as $1 - \frac{\alpha}{n}$) to correct for $n$ comparisons of 9 clinical outcomes in 22 categories of genetic disorders and accepting statistical significance at a Bonferroni corrected, two-tailed $\alpha$ of 0.05. Analyses were made using RStudio (version 2022.02.0; script in eMethods).

Results
Prevalence of commonly diagnosed genetic disorders in preterm infants.

Genetic disorders were identified in 5,838 (1.42 %) of the 409,704 infants in this cohort (Table 1). Of the 5,838 infants with a genetic diagnosis, 2706 (46.35%) were females, 3121 (53.46%) were males, and 11 (0.19%) were infants with ambiguous genitalia. The disorders included in the dataset were comprised of 19 specific diagnoses, as well as unspecified aneuploidy, unspecified copy number variant, and infants found to have multiple genetic disorders. Aneuploidies (trisomy 13, 18, 21, and 22, Klinefelter syndrome, Turner syndrome) were present in 2,804 infants, with trisomy 21 accounting for more than half (1,463) of these cases. Copy number variants (13q deletion, Cri-du-chat syndrome, DiGeorge syndrome) were present in 155 infants. Unspecified aneuploidy and copy number variants were noted in 856 and 54 infants respectively. Eleven distinct monogenic disorders were identified in 2,859 infants. Most (2,449) of these had hematologic disorders. Thalassemia accounted for 1,485 cases. Sickle cell disease was identified in 252 infants and cystic fibrosis in 274. 20 infants with multiple genetic disorders were identified.

Association of commonly diagnosed genetic disorders with severe morbidity and mortality in preterm infants.

Following exclusions, 320,582 preterm infants remained for analysis of clinical outcomes. Genetic disorders were prevalent in 4,196 (1.3%) of these individuals. The rate of mortality in preterm infants without genetic disorders in this cohort, and following exclusions was 5.3%. Genetic disorders were present in 566 (3.2%) of preterm infants who died, in 1,319 (2.0%) of preterm infants who experienced any severe morbidity or mortality, in 3,630 (1.2%) of preterm
infants who survived to discharge, and in 2,664 (1.1%) of preterm infants who survived to
discharge free of severe morbidity. The mortality rate after exclusions for each genetic disorder
is provided in Table 1. The highest crude rates of mortality were found in cases of aneuploidy.
84.5 and 83.9% of preterm infants with trisomy 13 and 18 died before discharge. 14.7% of
preterm infants with trisomy 21 died before discharge. Mortality rates for preterm infants with
copy number variants varied from 12.5% in Cri-du-chat syndrome to 20.0% in cases of
unspecified copy number variants. Preterm infants with hematologic disorders had lower
observed rates of mortality, with the highest rates found in cases of sickle cell disease (2.6%)
and thalassemia (2.2%). Varying rates of mortality were noted in preterm infants with
miscellaneous monogenic disorders, including 9.7% mortality for infants with cystic fibrosis.

We then determined the crude and adjusted odds of severe morbidity and mortality for
preterm infants with diagnosed genetic disorders as compared to preterm infants without
known genetic disorders. The baseline characteristics for covariates used in these analyses are
provided for preterm infants with aneuploidies (Supplemental Table 1), copy number variants
(Supplemental Table 2), hematologic disorders (Supplemental Table 3), and miscellaneous
monogenic disorders (Supplemental Table 4). The number of preterm infants experiencing
morbidity and mortality for each diagnosed genetic disorder appears in Supplemental Table 5.

Preterm infants with aneuploidies had significantly greater adjusted odds of several outcomes
(Table 2). Preterm infants with trisomy 13, 18, and 21 had greater adjusted odds of death.
Preterm infants with trisomy 13 also had greater adjusted odds of AKI. Preterm infants with
trisomy 21 had greater adjusted odds of AKI, BPD, sepsis, shock, and death. Preterm infants with copy number variants and hematologic disorders were not found to have significantly greater adjusted odds of morbidity or mortality (Tables 3 and 4). The only monogenic disorder diagnosis associated with significantly increased adjusted odds of morbidity or mortality was cystic fibrosis (Table 5). Preterm infants with cystic fibrosis had significantly increased adjusted odds of NEC, BPD, and ROP. Elevated risk of morbidities in preterm infants with hypophosphatasia did not persist after adjustment for known risk factors.

Discussion

This study provides the most comprehensive determination to our knowledge of the prevalence of genetic disorders in preterm infants and short-term risk of morbidity and mortality conferred by genetic disorders in this population. We found that genetic disorders, consisting of aneuploidies, copy number variants, and monogenic disorders, were diagnosed in 1.4% of preterm infants. Trisomy 13, 18, and 21, and cystic fibrosis were associated with increased risk of morbidity or mortality after adjustment for known risk factors. Rates of comorbidities for preterm infants with trisomy 13 and 18 may be underestimated given mortality as a competing outcome, particularly following redirection to palliative goals of care.

The overall prevalence of genetic disorders may reflect a contribution of genetic disease to shorter gestation. Several of the most prevalent genetic disorders we analyzed are associated with preterm birth including hemoglobinopathies, cystic fibrosis, and common aneuploidies. This results from a complex interplay of factors including disrupted
placentation, increased risk of fetal growth restriction and stillbirth, closer monitoring of pregnancy, greater maternal age contributing to aneuploidy and risk of preterm birth, as well as idiopathic factors.

We found prevalence rates of trisomy 13 and 18 lower than previously described in preterm infants, however our analysis used a gestational age-based cutoff rather than birth weight. Trisomy 13 and 18 cause fetal growth restriction. Given the same study population, a weight-based cutoff will select for infants with gestational age > 33 weeks with these genetic disorders and estimate a higher prevalence rate. Given these selection differences, it is difficult to compare morbidity and mortality between our cohorts and previous descriptions.

Interestingly, we found increased adjusted odds of NEC, BPD, and ROP in preterm infants with cystic fibrosis. Infants with cystic fibrosis have been found to be born at earlier gestational age and with lower birth weight. However, after adjustment for these factors, we found an increased risk of morbidity. Intestinal disease caused by meconium peritonitis and meconium ileus may mimic or predispose infants to NEC. BPD and ROP may be attributable to disrupted lung disease, and exposure to oxygen. Maternal cystic fibrosis also contributes to neonatal morbidity, and may account for a portion of observed outcomes. However, maternal diagnoses were not available in our cohort.

This retrospective study has significant strengths and important weaknesses. It encompasses a large number of infants, cared for in multiple institutions, and is highly generalizable. The depth
of data, including patient characteristics, diagnoses of genetic disorders, and co-morbidities should enable clinicians to better counsel families and inform clinical decision-making in rare presentations. It encompasses a broad period, during which genetic testing has undergone considerable change. This may contribute to heterogeneity in the cohort with respect to year of birth. As genome-wide testing becomes more common, genetic disorders may be diagnosed more frequently in this population. This dataset lacks information regarding social determinants of health and maternal access to care (including genetic testing). Multiple factors could have contributed to over- or underestimation of the prevalence of genetic disorders. Preterm infants experience high rates of morbidity and mortality, which may prompt testing for genetic disease in some settings. Genetic disorders often present non-specifically in preterm infants,\textsuperscript{4,28} compared to more complete phenotypes found in term infants or pediatric or adult populations. Therefore, genetic disorders may have gone undetected in this cohort.

Unfortunately, we do not have data regarding the extent of pre- and postnatal genetic testing, including negative results, in this cohort. Crucially, these data do not include broad, prospective screening for genetic disorders, but rather only the retrospectively provided data from electronic health records. Given the prevalence of genetic disorders we found, particularly in preterm infants who experienced morbidity or mortality, there is a crucial need for broad, prospective studies to establish the true prevalence of genetic disorders in preterm infants and to determine the portion of morbidity and mortality attributable to genetic disorders in this population.
In summary, using a multicenter retrospective cohort, we found that genetic disorders are present in 1.4% of infants born before 34 weeks' gestation, and that trisomy 13, 18, 21, and cystic fibrosis are associated with greater adjusted odds of death or severe morbidity. We determined the prevalence of 19 distinct genetic disorders, and the crude and adjusted risk of mortality and severe morbidities. These data may help clinicians provide more informed guidance to families and lead to better clinical decision-making in rare presentations. These data indicate the need for a greater index of suspicion for multiple critical illnesses, such as sepsis in the setting of trisomy 21 and NEC in the setting of cystic fibrosis. Given the trend towards greater adjusted odds of multiple morbid outcomes, clinicians should also consider genetic evaluation when caring for preterm infants with critical illnesses. Prospective, genome-wide screening is needed to determine the true prevalence of genetic disorders in this high-risk population, the contribution of genetic disorders to preterm birth, and the portion of disease in preterm infants attributable to genetic disorders.
