Abstract:

Aim. To assess the antibiotic prophylaxis in the prescriptions of the patients attending the Dental Outpatient department in a Tertiary care hospital. Background. Antibiotics are most-commonly used in outpatient setting when compared to inpatient setting in dental department. American Dental Association guidelines for antibiotic use for dental infections plays an important role in reducing prescribing for common conditions in dentistry. As there is no proper evidence regarding efficient use of antibiotic prophylaxis in dentistry, this study is aimed to address the prophylactic use of appropriate antibiotics among the outpatients in dental department. Methods. This Retrospective Observational study was conducted in the dental outpatient department in a tertiary care hospital for a month. The data regarding the Antibiotic prophylaxis along with underlying cardiac conditions were collected from records of the patients’ prescription and analysed using Simple statistics. Results. A total of 150 prescriptions (Male = 78 & Female = 72) are collected. Mean age was found to be 45.8 years (0 - 90). Most dental diagnosis are Scaling, Tooth extraction, Dental caries, Luting, Filling, Splint placing, Impacted tooth, Dental Abscess and Other Procedures. 88 prescriptions were found to have Antibiotic prophylaxis, where Amoxicillin is the most prescribed antibiotic. 2 days is the mostly prescribed duration of Antibiotic therapy. 13 Prescriptions had patients with underlying cardiac conditions who were prescribed with antibiotics prophylaxis. Conclusion. The antibiotic prescribing pattern in Dental outpatient department was assessed and it was found that 85% of patients were prescribed with antibiotics other than patients with underlying cardiac conditions.

Keywords: Antibiotics, Antimicrobial stewardship, Prophylaxis, Prescribing patterns, Dental, Outpatients.
INTRODUCTION:
Antibiotics are frequently prescribed by dentists in the outpatient setting when compared to the inpatient setting to treat odontogenic, nonodontogenic, local, focal infections as well as prophylaxis [1]. Unnecessary prescription and misuse of antibiotics result from a lack of information regarding the appropriate use of antibiotics and its administration, which leads to antibiotic resistance as a result of improper antibiotic prescription procedures [2].

Antibiotics prescribed in dentistry are mostly empirical, which means clinicians do not identify the causative bacteria causing the infections as the culture tests are not performed frequently. Frequent use of broad-spectrum antibiotics has led to widespread rise in the establishment of antibiotic resistance for oral microorganisms [3].

Prescribing antibiotics before surgery to reduce the risk of postoperative infections is known as preoperative antibiotic prophylaxis [4]. There is still debate over the efficacy of prophylaxis despite its lengthy history of usage and several recommendations. The recommendations for antibiotic prophylaxis have undergone substantial revisions in the previous ten years. These changes have been driven partly by global concerns about antimicrobial resistance [5] and following advice that any antibiotic prescription should be sensible and appropriate [6]. Additionally, routine prophylactic usage for dental treatments is no longer advised [7].

Use of antibiotics in dental care is common in India [8]. Previous studies analysing the knowledge and prescription habits of dental professionals in India revealed improper prescribing of antibiotics [9]. While information on the use of antibiotics in dentistry has been gathered and is available in high-income countries, it is limited in low- and middle-income countries like India.

As there is no proper evidence regarding efficient use of antibiotic prophylaxis in dentistry, this study is aimed to address the prophylactic use of appropriate antibiotics among the outpatients in the dental department.

AIM:
We aim to assess the patterns of antibiotic prescribed for outpatients in the dental department in a Tertiary Care Hospital and to assess the choice of antibiotic regimens and duration of antibiotic therapy.

MATERIAL AND METHODS:
This retrospective observational study was conducted in the dental outpatient department (OPD) of a tertiary care hospital after obtaining prior institutional ethics committee approval. The study was done for a period of 1 month from May 2022 to June 2022.

Patients who are attending the dental OPD during the study period and all age groups of both genders were included. Subjects whose case records are not available, above the age of 90 years, pregnant and lactating women are excluded from the study.

The primary outcome of the study is to assess the prescribing patterns of antibiotics in OPD to improve the antibiotic prophylactic use for Outpatients in the dental department.
Data Collection

Data from the prescriptions of outpatients attending the department of dental OPD were recorded. Each subject’s age, gender, dental diagnosis, Antibiotic prophylaxis, name of the antibiotics along with their date of Initiation of antibiotics, dose, frequency, duration of antibiotic therapy along with underlying cardiac conditions were collected from the records of the subjects’ prescription.

Data Analysis

The data are collected using google forms and analysed using simple statistics.

RESULTS:

A total of 150 prescriptions are collected, of which 78 (52%) were males and 72 (48%) were females. Mean age was found to be 45.8 years (SD. 18). The prescriptions of the age group 41-50 were found to be most common among other age groups. Most patients come to dental OPD for procedures depicted in Figure 1.

Figure 1. Dental Diagnosis/Procedures in Dental OPD
Out of 150 prescriptions, 88 (58.7%) prescriptions were found to have Antibiotic prophylaxis, where Amoxicillin (72.7%) is the most prescribed antibiotic. Apart from Amoxicillin, other antibiotics were prescribed as depicted in Figure 2.

Figure 2. Antibiotics prescribed in Dental OP

62 (41.3%) prescriptions do not have antibiotic prophylaxis. The duration of Antibiotic therapy differs in each prescription, where 2 days is the mostly prescribed duration in Table 1 as follows.

Table 1. Duration of Antibiotic therapy in Dental OP

13 (8.7%) Prescriptions had patients with underlying cardiac conditions who were prescribed with antibiotic prophylaxis – Amoxicillin 500 mg (4 capsules) one hour before procedure and Amoxicillin 500 mg (2 capsules) 6 hours after procedure. For some patients, one dose of Co-amoxiclav 625 mg is given as prophylaxis before procedure.

Totally 13 (15%) patients with underlying cardiac conditions are prescribed with antibiotics whereas 75 (85%) patients without cardiac conditions were also prescribed with antibiotics.

DISCUSSION:

As per the ADA guidelines, it is recommended that antibiotics should not be used for most of the pulpal and periapical conditions and it also recommended dentists to prescribe antibiotics if the patients’ condition progress to systemic involvement showing the signs of fever or malaise [10]. In a review article, it is recommended that apart from endocarditis and late prosthetic joint infections, there is no need for antibiotic prophylaxis in dentistry [11]. But in our study, most of
the patients are prescribed with antibiotics for dental prophylaxis regardless of any underlying cardiac conditions.

According to a retrospective cross-sectional analysis by MJ Durkin et al (2017), dentists frequently prescribe antibiotics for prolonged period where the treatment duration were 7 and 10 days and dentists often use broad spectrum antibiotics, such as Amoxicillin-clavulanate and Clindamycin [12]. In our study, 72.7% of the patients were prescribed with Amoxicillin whereas 27.3% of the patients were prescribed with other antibiotics such as Cefixime, Cefuroxime, Amoxicillin-clavulanate and Amoxicillin + Metronidazole with duration of antibiotics between 1 – 5 days.

Patients with underlying cardiac conditions are prescribed with preoperative prophylaxis where Amoxicillin 500 mg (4 capsules) is given one hour before procedure and for some patients, one dose of Co-amoxiclav 625 mg is given before procedure. But according to NICE guidelines, in patients with heart conditions, it is necessary to use amoxicillin 3 g or Clindamycin 600 mg orally 1 hour before procedure [13]. This study demonstrates the most antibiotics prescribed for dental prophylaxis in patients without any underlying cardiac conditions are unnecessary.

CONCLUSION:

85% of the patients were prescribed with antibiotics other than the patients with underlying cardiac conditions. It is necessary to implement dental antibiotic stewardship to reduce unnecessary use of antibiotics in dental prophylaxis and large multicentric studies in future will help to improve dental antibiotic stewardship in the developing world.

Ethical statement:

Ethics approval was obtained from institutional ethics committee of SIMS hospitals, Vadapalani, Chennai, Tamil Nadu, India (IEC Number: SIMS IEC/Others/24/2022).

Informed consent:

The participant has consented to the submission of the article to the journal.

Declaration of conflicting interests:

The authors declared no potential conflicts of interests with respect to research, authorship, and/or publication of this article.

Funding:

The authors received no financial support for the research, authorship, and/or publication of this article.

Sub: A Retrospective Observational Study on assessing the use of Antibiotics prophylaxis for outpatients in the Dental department in a Tertiary Care Hospital - IEC Approval

Dear Dr. D. Suresh Kumar,

Based on the response letter dated 28-Jul-2022, for the queries raised by the ethics committee held on 28-Jun-2022, the Ethics committee approves the study in the presented format.

Conduct the study as per the study protocol. In case of any changes, prior approval from IEC is required.

Submit the final report to Ethics Committee once the study is completed.

In all future correspondence with IEC, please quote the IEC number.
Find the enclosed list of members who attended the meeting.
