ABSTRACT

Background: Infertility is a global health issue that affects millions of couples worldwide. In Nigeria, the prevalence of infertility is particularly high underscoring the need for a better understanding of the factors contributing to male infertility at which Seminal Fluid Analysis (SFA) is the most important characteristics. This study aimed to assess the prevalence of abnormal seminal fluid and its associated factors among patients attending fertility clinics in Osogbo, Nigeria.

Methods and Findings: A descriptive cross-sectional study design was used among male patients attending fertility centers in Osogbo, Osun State. Fisher's formula \( n = \frac{z^2pq}{d^2} \) was used to determine the sample size. 305 respondents were selected using multistage sampling technique. Pre-tested questionnaire was used to collect data from respondents. Patients who consented to the study were also made to undergo seminal fluid analysis. The results were analysed using IBM Statistical Product for Service Solution (SPSS) version 27. Descriptive statistics was used for all variables. Bivariate and multivariate analysis were done at \( p<0.05 \) as level of significance. Majority of the respondents, 257 (84.3%) had at least one abnormality of Seminal fluid. Multiple regression analysis revealed that respondents who were habitual drunkard were about five times more likely to have at least one abnormality in their seminal fluid (OR: 4.990, \( p: 0.004 \), C.I.: 1.688-14.749) and smokers were three times more likely to have at least one abnormality in their seminal fluid (\( p=0.005 \), OR=3.300 and C.I=1.396-4.273). Also, respondents with history of sexually transmitted infection were 3.5 times more likely to have at least one abnormality in their seminal fluid (\( p=0.039 \), OR=3.595 and C.I=1.072-14.146).

Conclusions: The study observed high prevalence of abnormal seminal fluid which was significantly associated with lifestyle habits such as smoking, alcohol as well as previous history of sexually transmitted infection. The study recommended that advocacy program for...
healthy lifestyle, early screening and public health education will further reduce the burden of
abnormal seminal fluid and by implication, infertility among couples.

**Keywords:** Male Infertility, Implications, Seminal fluid Analysis, Sperm count.

**INTRODUCTION**

Infertility is a global health issue that affects millions of couples worldwide. The inability to
conceive a child after a year of regular, unprotected intercourse is a distressing experience for
many couples, leading to emotional, psychological, and social challenges. [1] In Nigeria, the
prevalence of infertility is particularly high, with studies showing that around 20-30% of
couples face fertility challenges. [2]

One of the most important aspects of male infertility is the quality and characteristics of the
seminal fluid. Seminal fluid, also known as semen, is a complex mixture of spermatozoa and
secretions from the male reproductive glands, including the seminal vesicles, prostate, and
bulbourethral glands. Seminal fluid plays a crucial role in the fertilisation process, providing
a supportive environment for sperm transport, nourishment, and protection against the female
reproductive tract's hostile conditions. [3]

Infertility is a significant public health concern affecting millions of couples worldwide, with
male infertility accounting for approximately half of these cases. [4] In Southwest Nigeria,
particularly, there is a noticeable gap in research regarding the seminal fluid analysis (SFA)
and its implications on male infertility among patients attending fertility clinics [5] Therefore,
this study aims to assess the prevalence of abnormal seminal fluid among male patients
attending fertility centers in Osogbo, Osun State, Nigeria.

**METHODS**

A descriptive cross-sectional study design was used in the study. The study population
were male patients attending fertility centers in Osogbo, Osun State. Fisher's formula
(n=z²pq/d²) was used to determine the sample size. 305 respondents were selected using multistage sampling technique. Out of 10 major fertility centers in Osogbo, Osun State, 5 centers were randomly selected. Proportional allocation was used to determine the number of respondents from each center. Male patients aged 18-50 were randomly selected in each center. Pre-tested questionnaire was used to collect data from respondents. Patients who consented to the study were also made to undergo seminal fluid analysis. The semen was collected aseptically after an abstinence period of 2–7 days using sterile universal bottles in a private room near the laboratory to limit the exposure of the semen to fluctuations in temperature and to control the time between collection and analysis. The semen was then analysed in the laboratory for sperm count, motility and morphology of the semen. The data from the questionnaire were analysed using IBM Statistical Product for Service Solution (SPSS) version 27. Descriptive statistics was used for all variables. Bivariate and multivariate analysis were done at p<0.05 as level of significance.

RESULTS

Sociodemographic characteristics of respondents
All the respondents were married male attending the infertility clinic in Osogbo. More than half 164 (53.8%) of the respondents were with the ages of 31-40 years, while the majority, 267(87.5%) were Yoruba. 164 (53.8%) had tertiary level of education followed by secondary 83 (27.2%). About half 140 (45.9%) were skilled workers while 110 (36.1%) were unskilled.

Prevalence of abnormal seminal fluid
Majority of the respondents, 84.3% had at least one abnormality while 15.7% have normal seminal fluid. About two-thirds 217 (71.1%) had normal sperm count (>32 million per ejaculation) while 88 (28.9%) had abnormal sperm count. Only 97 (31.8%) had normal progressive motility (>32 percent) while 208 (68.2%) had abnormal (Athenospermia)
progressive motility and 178 (58.4%) were found to have abnormal morphology (Teratospermia i.e., <4%). (Figure 1)

Association between medical history of respondents and abnormal seminal fluid among respondents

Majority of the respondents 65 (91.5%) who were diabetic had at least one abnormality in seminal fluid. Majority of the respondents 29 (96.7%) who were hypertensive had at least one abnormality in seminal fluid. Majority of the respondents 49 (90.7%) who were overweight had at least one abnormality in seminal fluid. However, there was no statistically significant association between these factors and abnormal seminal fluid.

Majority of the respondents 84 (96.6%) who had history of sexually transmitted infection had at least one abnormality in seminal fluid and this was statistically significant (p<0.001). (Table 2)

Predictors of abnormal seminal fluid among respondents

Multiple regression analysis revealed that respondents who were habitual drunkard were about five times more likely to have at least one abnormality in their seminal fluid (OR: 4.990, \(p=0.004\), C.I.: 1.688-14.749) and smokers were three times more likely to have at least one abnormality in their seminal fluid (\(p=0.005\), OR=3.300 and C.I=1.396-4.273). Also, respondents with history of sexually transmitted infection were 3.5 times more likely...
to have at least one abnormality in their seminal fluid (p=0.039, OR=3.595 and C.I=1.072-14.146).

Discussion

This study assessed the prevalence of abnormal seminal fluid and its associated factors among patients attending fertility clinics in Osogbo, Osun State, Nigeria. More than half of the respondents were between the ages of 31 and 40 years old while more than two-fifth were aged 21-30 years. More than half of the respondents have tertiary as their highest educational attainment. This is similar to another study conducted among male partners attending infertility clinic in a tertiary Nigerian hospital [6]

More than four-fifth of the respondents had at least one abnormality. About one-third had abnormal sperm count, which is below the WHO 2010 reference for semen analysis. [7] This proportion is also lower compared to the study of [8] where more than four-fifths were found to have abnormal sperm count. Almost 7 out of 10 respondents had abnormal (Athenospermia) progressive motility) which is more than the WHO 2010 reference of <32%. [7] Furthermore, this proportion is higher compared to another study carried out among male partners of infertile couples seeking care at the Lagos University Teaching Hospital where 55.8% had abnormal progressive motility. [9] Also, about three-fifth had abnormal morphology (Teratospermia i.e., <4%). This proportion is much higher compared to 60.8% of abnormal morphology reported in the study of [6] among male patients in a tertiary Nigerian hospital.

The predictors of abnormal seminal fluid among respondents included smoking, drinking, and previous history of sexual transmitted infection such that respondents who were habitual drunkard were about five times more likely to have at least one abnormality in
their seminal fluid (OR: 4.990, p: 0.004, C.I.: 1.688-14.749) and smokers were three times
more likely to had at least one abnormality in their seminal fluid (p=0.005, OR=3.300 and
C.I=1.396-4.273). Also, respondents with history of sexually transmitted infection were 3.5
times more likely to have at least one abnormality in their seminal fluid (p=0.039,
OR=3.595 and C.I=1.072-14.146). This was also evident in the study of [6] where age,
smoking and alcohol consumption were reported as the possible risk factors for abnormal
sexually transmitted infection. This suggests that substance abuse, habitual smoker,
drinking habit have detrimental impact on reproductive health and fertility as it has been
associated with reduced sperm count, motility, and normal morphology. It is also linked to
increased levels of sperm aneuploidy, lower seminal plasma antioxidant levels, and
increased oxidative damage to sperm deoxyribonucleic acid (DNA). [10]

Conclusions: The findings indicate a prevalence of abnormal seminal fluid parameters (low
sperm count, motility, and morphology) among the participants in which motility has the
highest prevalence followed by morphology and sperm count respectively. Lifestyle factors
such as smoking, alcohol consumption and sexually transmitted infections were found to be
significantly associated with abnormal seminal fluid. The implications of abnormal seminal
fluid parameters on infertile males are substantial, extending beyond physical health to
encompass psychological, emotional, and social well-being. The findings from this study
indicates the need for increased awareness about male infertility and accessibility to male
fertility testing in order to combat the issue of infertility among couples. Further studies can
assess the effect on seminal fluid analysis on male infertility.

**Limitation**

The study is limited to patients attending fertility centers in Osogbo, which can have effect on the generalization of the study. Also, due to the nature of the study as a cross-sectional study, causal relationship may not be established.

**Ethical approval and consent to participate**

Ethical approvals for this study were obtained from the Ethics and Research Committee of Adeleke University, Ede, and Uniosun Teaching Hospital. The Protocol number UTH/EC/2024/06/957. All ethical principles guiding the conduct of research such as informed consent, beneficence, non-maleficence, confidentiality, justice, autonomy etc were strictly taken into consideration. All information gathered were confidential and privacy and confidentiality of the respondents were guaranteed. All respondents were made to sign the informed consent before filling the questionnaire.
