11 **Abstract**

12 **Background**—Acute ischemic stroke (AIS) leads to a substantial burden of disease among
13 the elderly. There may be a delay in or a poor outcome of endovascular treatment (EVT)
14 among AIS patients with large-vessel occlusion (LVO) during off-hours. By using a
15 prospective, nationwide registry, we compared the workflow intervals and
16 radiological/clinical outcomes between patients with acute LVO treated with EVT presenting
17 during off- and on-hours.

18 **Methods**—We analyzed prospectively collected Endovascular Treatment Key Technique and
19 Emergency Work Flow Improvement of Acute Ischemic Stroke (ANGEL-ACT) data. Patients
20 presenting during off-hours were defined as those presenting to the emergency department
21 from Monday to Friday between the hours of 17:30 and 08:00, on weekends (from 17:30 on
22 Friday to 08:00 on Monday), and on national holidays. We used logistic regression models

1 with adjustment for potential confounders to determine independent associations between the
2 time of presentation and outcomes.

3 **Results**—Among 1788 patients, 1079 (60.3%) presented during off-hours. The median
4 onset-to-door time and onset-to-reperfusion time were significantly longer during off-hours
5 than on-hours (165 vs 125 minutes, $P=0.002$ and 410 vs 392 minutes, $P=0.027$). However,
6 there were no significant differences between patients presenting during off- and on-hours in
7 any radiological/clinical outcomes (mRS score: 3 vs 3 points, $P=0.204$; mortality: 15.9% vs
8 14.3%, $P=0.172$; successful reperfusion: 88.5% vs 87.2%, $P=0.579$; sICH: 7.2% vs 8.4%,
9 $P=0.492$).

10 **Conclusions**—Off-hours presentation in the nationwide real-world registry was associated
11 with a delay in the visit and reperfusion time of EVT in patients with AIS. However, this
12 delay did not lead to worse radiological/clinical outcomes.

14 **Key Words:** endovascular treatment; off-hours; acute ischemic stroke; large vessel occlusion

15

1 Introduction

2 Stroke is the leading cause of death and disability in China¹. Ischemic stroke accounts
3 for 65%² of stroke patients in China, of whom 35-40% have large-vessel occlusion (LVO)¹.
4 LVO results in a large ischemic area and can cause severe brain damage^{3,4}, leading to high
5 mortality and disability rates⁵⁻⁷. As a landmark in the treatment of acute ischemic stroke (AIS)
6 with proximal intracranial LVO⁸⁻¹², endovascular treatment (EVT) has been widely used in
7 real-world clinical practice. However, stroke causes 2 million neurons to undergo apoptosis
8 every minute, and the brain ages 3.6 years per hour¹³. Therefore, performing EVT as soon as
9 possible in patients with LVO is the key to improving the prognosis^{14, 15}.

10 Approximately half of patients present during so-called off-hours, i.e., evenings, nights,
11 weekends, and holidays, and EVT needs to be performed jointly by emergency department
12 staff, digital subtraction angiography (DSA) room nurses, technicians, anesthesiologists, and
13 surgeons. Therefore, off-hours presentation may be associated with a delay in the start of
14 EVT. The MR CLEAN trial found that presentation during off-hours was associated with a
15 slight delay of EVT but that this treatment delay did not translate into worse functional
16 outcomes or an increased rate of complications¹⁶. Data on off-hours delays in workflow
17 intervals have shown delays in different workflow intervals and related performance, but
18 these data are mostly based on single-center studies and are difficult to interpret because of
19 variations in acute stroke care¹⁷⁻²⁰. However, there have been no multicenter studies on the
20 association of off-hours presentation and EVT workflow intervals in Chinese patients with
21 LVO.

1 The Endovascular Treatment Key Technique and Emergency Work Flow Improvement
2 of Acute Ischemic Stroke (ANGEL-ACT) registry was established to evaluate the utilization
3 and subsequent outcomes of AIS patients who received EVT and has confirmed that
4 favorable outcomes of EVT can be achieved in clinical practice in China²¹. In this study, we
5 analyzed prospectively collected ANGEL-ACT data to observe whether the workflow
6 intervals and radiological/clinical outcomes were different between patients with acute LVO
7 treated with EVT who presented during on- versus off-hours.

8 **Methods**

9 **Study Participants**

10 Data were derived from the ANGEL-ACT registry. ANGEL-ACT was a nationwide,
11 prospective, observational study of 1793 consecutive adult patients with acute LVO treated
12 with EVT at 111 hospitals from 26 provinces in China between November 2017 and March
13 2019 (<https://www.clinicaltrials.gov>; unique identifier: NCT03370939). Detailed information
14 about the ANGEL-ACT registry can be found in a previously published article²¹. Ethics
15 approval was granted by the ethics committees of Beijing Tiantan Hospital and all
16 participating centers. Subjects or their representatives provided written informed consent.

17 For the present study, patients who adhered to the following criteria were included: (1)
18 age ≥ 18 years; (2) diagnosis of AIS on computed tomography (CT) angiography confirming
19 intracranial LVO; and (3) initiation of any type of EVT, including mechanical thrombectomy,
20 intra-arterial thrombolysis, stenting and angioplasty. Patients were divided into the on-hours
21 group and the off-hours group based on their presentation time.

22 **Data Collection and Outcome Measures**

1 Off-hours presentation was defined as presentation to the emergency department
2 (participating centers) from Monday to Friday between the hours of 17:30 and 08:00, on
3 weekends (from 17:30 on Friday to 08:00 on Monday), and on national holidays.

4 All variables, including demographic data, medical history, vital signs, laboratory and
5 neurovascular imaging results, workflow intervals, and clinical outcomes, were prospectively
6 collected.

7 The workflow intervals included the door-to-puncture time, onset-to-puncture time,
8 onset-to-door time, door-to-imaging time, onset-to-needle time, puncture-to-reperfusion time
9 and onset-to-reperfusion time. The radiological and clinical outcomes included the 90-day
10 modified Rankin Scale (mRS) score as an ordinal variable, functional independence (defined
11 as a 90-day mRS score from 0 to 2), mortality within 90 days, successful reperfusion (defined
12 as the modified Thrombolysis in Cerebral Infarction [mTICI] score of 2b or 3²²), and
13 symptomatic intracranial hemorrhage (sICH) within 24 hours according to the Heidelberg
14 Bleeding Classification²³.

15 **Statistical Analysis**

16 Statistical analyses were performed using SAS 9.4 (SAS Institute, Inc., Cary, NC). All
17 data are described as the median (interquartile range [IQR]) for continuous/ordinal variables
18 and number (percentage) for categorical variables. The Wilcoxon test was used
19 for continuous/ordinal variables, and Fisher's exact test or the chi-square test was used for
20 categorical variables. A *P*-value of < 0.05 was considered statistically
21 significant. Multivariable logistic regression models were used to determine the independent
22 associations between the time of presentation (on- versus off-hours) and radiological/clinical

1 outcomes, with adjustment for age, pre-treatment with intravenous thrombolysis (IVT),
2 baseline NIHSS score, occlusion site, pre-stroke mRS score, and onset-to-door time.

3 **Results**

4 **Baseline Characteristics**

5 Among the 1793 subjects included in the ANGEL-ACT registry, 5 were excluded
6 because the admission time was missing, leaving 1788 patients eligible for analyses. In total,
7 1079 patients (60.3%) presented to the emergency department during off-hours, and 709
8 (39.7%) presented during on-hours. The baseline characteristics were similar in both groups
9 except for the proportion of transferred patients. More patients in the off-hours group than in
10 the on-hours group were transferred from primary stroke centers (36.98% versus 32.02%,
11 $P=0.033$) (Table 1).

12 **Workflow Intervals**

13 The median onset-to-door time during off-hours presentation was 165 (IQR: 70-295)
14 minutes, which was significantly longer than that during on-hours presentation (125 [IQR:
15 60-260] minutes, $P=0.002$). The median onset-to-reperfusion time was also significantly
16 longer during off-hours (410 [IQR: 310-561] minutes versus 392 [IQR: 285-546] minutes,
17 $P=0.027$). The door-to-puncture time, onset-to-puncture time, door-to-imaging time,
18 onset-to-needle time and puncture-to-reperfusion time were similar between the two groups
19 (Table 2).

20 **Radiological and Clinical Outcomes**

21 No difference was found in the 90-day mRS score between on- and off-hours
22 presentation (median: 3 vs 3 points, adjusted common OR=0.892, 95% CI=0.748–1.064)

(Table 3 and Figure 1). We also found no difference between the two groups in the occurrence of functional independence (adjusted OR=0.892, 95% CI=0.724–1.098). The rates of successful reperfusion, mortality within 90 days and sICH were similar in both groups (Table 3).

Discussion

This large-scale multicenter study reported the relationship of on- and off-hours presentation with workflow intervals and radiological/clinical outcomes and included over 1700 patients treated at 111 different comprehensive stroke centers in China. This study showed that although treatment was administered 40 minutes later in AIS patients presenting off-hours than in those presenting on-hours, there was no difference in the rate of functional independence at 90 days or in the mRS score distribution. In addition, there was no difference in the door-to-puncture time, the rates of successful reperfusion or sICH.

Similar to previous multicenter studies^{16, 24-27}, this study did not reveal a difference in the prognosis or rate of complications between the two groups. Benali et al observed a significantly higher rate of good functional outcomes among inpatients admitted at night (51% vs. 35%, $P = 0.05$)²⁸, but another study found a higher mortality rate among patients admitted at night for EVT²⁹, which may be due to the heterogeneity of the stroke center process and sample size. Although this multicenter study did not observe an effect of on- versus off-hours presentation on the prognosis, exploring differences in the workflow intervals between the two groups may help to improve the efficiency of EVT implementation. Our research showed that the median onset-to-reperfusion time in off-hours patients was 410 minutes, 18 minutes longer than that in on-hours patients, indicating that there is a certain

1 delay in the EVT process for patients presenting off-hours. The times from onset to door,
2 door to puncture and puncture to reperfusion need to be analyzed to assess the impact of
3 off-hours presentation on the EVT process.

4 Off-hours patients have a longer onset-to-door time. The 40-minute gap suggests more
5 delays before the hospitalization of off-hours patients. Experiencing a stroke after waking up
6 at night may be an important contributing factor. Another factor may be transfers, as a higher
7 proportion of off-hours patients required transfer. We speculate that some hospitals may not
8 have the capability to provide EVT over 24 hours, so patients who are first diagnosed at these
9 hospitals during off-hours may need to be transferred to a suitable stroke center. Previous
10 research has also described this phenomenon¹⁶. Notably, in the treatment of patients requiring
11 EVT, interhospital transfer will increase the onset-to-first door time³⁰⁻³²; therefore, in
12 establishing the EVT process, the delay caused by referral should be recognized, special
13 attention should be given to the impact of off-hours referrals, and effective publicity should
14 be used to make patients aware of hospitals with 24-hour EVT capabilities in advance so that
15 patients can be delivered directly after stroke onset.

16 The overall door-to-puncture time in this study was 124 minutes, which is much higher
17 than the 85 minutes reported in a prospective, randomized, controlled study conducted in
18 China³³ and exceeds the requirement of 90 minutes of advanced Chinese stroke centers,
19 suggesting that the EVT process needs to be further optimized in the real world. However, we
20 observed that the door-to-puncture time was similar in the off-hours group and the on-hours
21 group, which suggests that the EVT process of the stroke center is as efficient off-hours as
22 on-hours and that the emergency green channel, CT examination and DSA are not delayed

1 due to rest. Therefore, this study confirms that presenting off-hours did not cause a delay in
2 the EVT door-to-puncture time in China.

3 We found that the reperfusion rate in the off-hours group was similar to that in the
4 on-hours group, while the puncture-to-reperfusion time in the off-hours group was 8 minutes
5 longer than that in the on-hours group. We speculate that such a time difference may come
6 from the availability of the off-hours intervention team. According to experience at our center,
7 for patients who require general intravenous anesthesia, the response of the anesthesiologist
8 during off-hours may not be as good as that during on-hours. Furthermore, more junior
9 doctors may be on duty during off-hours, the interventionalists available off-hours may not be
10 as experienced as those available on-hours, and physician or staff fatigue during late-night
11 procedures may cloud judgment or increase the risk of procedural complications^{34, 35}. In the
12 future, attention needs to be given to optimizing the configuration of the intervention team
13 during off-hours to reduce the puncture-to-reperfusion time.

14 The definition of off-hours was set according to statutory holidays and time nodes. The
15 ANGEL-ACT registry contains data from 111 hospitals in 26 provinces in China²¹. These
16 hospitals share Beijing time in Dongba District, which is the standard time in China.
17 Therefore, there is a possibility that when Dongba District has entered the evening, the
18 Eastern Fifth District may still be during the day, so it is necessary to carefully define
19 off-hours. We analyzed the locations of the 111 hospitals and found that 106 (95.4%)
20 hospitals were located in the time zone of the East 8th District and East 7th District. These
21 hospitals accounted for 1716 (95.9%) patients, which means that the time zone difference of
22 95.9% patients was no more than 1 hour. We conducted a survey on the work and rest time of

1 all hospitals in the group;98.2% of the hospitals' work hours are 7:30-18:30, with off-hours
2 of 17:00-8:00 in both summer and winter. Therefore, it is reasonable to choose 08:00 and
3 17:30 when defining the time nodes of off-hours.

4 This study has some limitations. First, 17 of 1788 patients did not have 3-month
5 follow-up data available from phone interviews; thus, the rates of poor outcomes or serious
6 events may have been underestimated. Second, Saad et al found that the workflow interval
7 had no effect on EVT in teaching hospitals but did have an effect on EVT in non-teaching
8 hospitals³⁶. Our study included stroke centers with 24-hour EVT capability, and most of them
9 were teaching hospitals. Therefore, whether the results can be extended to all stroke centers
10 in China still needs further study. Finally, our definition of off-hours included statutory
11 holidays. However, some hospitals included in the study follow a normal work schedule on
12 statutory holidays, and some hospitals even have a 24-hour neurointervention emergency
13 team on duty. This may be the reason why the prognosis of Chinese patients receiving EVT
14 during on-hours and off-hours was similar.

15 **Conclusion**

16 In conclusion, according to the nationwide real-world registry, off-hours presentation
17 was associated with a delay in the visitand reperfusion time of EVT in patients with AIS, but
18 this delay did not lead to worse radiological and clinical outcomes. In future optimization of
19 the EVT process during off-hours, the onset-to-door time and onset-to-reperfusion time can
20 be key targets for improvement.

1 Table 1. Baseline Characteristics (median, IQR/ n, %)

Items	On-hours (n=709)	Off-hours (n=1079)	<i>P</i>
Age,y	65(55-73)	66(56-73)	0.496
Men	469(66.2)	705(65.3)	0.760
Baseline NIHSS (n=1780)	16(12-22)	16(12-21)	0.320
PremRS (n=1787)	0(0-0)	0(0-0)	0.539
Baseline ASPECTS (n=1773)	9(7-10)	9(7-10)	0.414
SBP (mmHg)	145(130-160)	145(131-162)	0.882
Medical history			
Hypertension	411(58.0)	616(57.1)	0.732
Diabetes	118(16.6)	213(19.7)	0.106
Hyperlipidemia	66(9.3)	93(8.6)	0.612
Coronary heart disease	111(15.7)	162(15.0)	0.737
Atrial fibrillation	217(30.6)	344(31.9)	0.602
Previous stroke	159(22.4)	238(22.1)	0.862
Smoking (recent or current)	292(41.2)	424(39.3)	0.430
IVT performed	491(69.3)	774(71.7)	0.265
Interhospital transfer	227(32.0)	399(37.0)	0.033
Anesthesia			0.384
Local anesthesia only	322(45.4)	455(42.2)	
General anesthesia	274(38.7)	447(41.4)	
Local anesthesia plus sedation	113(15.9)	177(16.4)	
Occlusion site			0.912
Internal carotid artery	185(26.1)	269(24.9)	
M1	298(42.0)	471(43.7)	
Basilar/ vertebral artery	149(21.0)	222(20.6)	
Other	77(10.9)	117(10.8)	
Stroke classification			0.875
Large atherosclerotic stroke	344(48.5)	533(49.4)	
Cardiogenic cerebral embolism	229(32.3)	346(32.0)	
Other stroke with definite etiology	79(11.1)	124(11.5)	
Stroke of unknown etiology	57(8.0)	76(7.0)	

2 Total number is 1788, unless otherwise indicated.

3 NIHSS indicates National Institutes of Health Stroke Scale; mRS, modified Rankin Scale; ASPECTS, Alberta

4 Stroke Program Early CT Score; SBP, systolic pressure; IVT, intravenous therapy; M1, first segment of the

5 middle cerebral artery.

6

1 Table 2. Workflow intervals (median, IQR)

Items	On-hours (n=709)	Off-hours (n=1079)	<i>P</i>
Door-to-puncture time (n=1787)	124.5(81.5-190)	123(83-175)	0.164
Onset-to-puncture time (n=1774)	290(200-431)	305(218-445)	0.078
Onset-to-door time (n=1754)	125(60-260)	165(70-295)	0.002
Door-to-imaging time (n=1523)	15(0-30)	14(0-28)	0.345
Onset-to-needle time (n=410)	160(110-220)	159.5(119.5-213)	0.843
Puncture-to-reperfusion time (n=1788)	80 (50-128)	88 (55-130)	0.078
Onset-to-reperfusion time (n=1774)	392(285-546)	410(310-561)	0.027

2

1 Table 3. Clinical outcomes (median, IQR/ n, %)

Items	On-hours (n=709)	Off-hours (n=1079)	Unadjusted OR (95% CI)	Unadjusted <i>P-value</i>	Adjusted OR (95% CI)	Adjusted <i>P-value</i>
mRS at 90 d (n=1771)	3(0-5)	3(0-5)	0.942(0.794-1.118)	0.493	0.892(0.748-1.064)	0.204
mRS (0-2) at 90 d (n=1771)	306(45.7)	466(44.7)	0.960(0.790-1.166)	0.691	0.892(0.724-1.098)	0.280
Reperfusion rate (TICI 2b-3) (n=1788)	618(87.2)	955(88.5)	1.134(0.850-1.514)	0.414	1.087(0.809-1.462)	0.579
Mortality at 90 d (n=1771)	101(14.3)	172(15.9)	1.142(0.875-1.490)	0.347	1.214(0.919-1.603)	0.172
sICH within 24h (n=1695)	56(8.4)	74(7.2)	0.842(0.586-1.209)	0.352	0.878(0.606-1.272)	0.492

2 mRS indicates modified Rankin Scale;TICI, Thrombolysis in Cerebral Infarction; sICH, symptomatic

3 intracranial hemorrhage.
