27	

Objectives: Socioeconomic inequalities in HIV prevention services coverage constitute
important barriers to global prevention targets, especially in sub-Saharan Africa (SSA). We
aimed at monitoring these inequalities from population-based survey data in 18 SSA countries
between 2010 and 2018.

Methods: We defined eight HIV indicators aimed at capturing uptake of HIV prevention services among adult participants. Country-specific wealth-related inequalities were measured using the Relative and Slope Index of Inequalities (RII and SII, respectively) and then pooled using random-effects meta-analyses. We compared inequalities between African regions using the Wilcoxon rank-sum test.

37 **Results**: The sample consisted of 358,591 participants (66% women). Despite variability 38 between countries and indicators, the meta-analysis revealed significant levels of relative and 39 absolute inequalities in 6 out of 8 indicators: HIV-related knowledge, positive attitudes toward 40 people living with HIV (PLHIV), condom use at last sexual intercourse, participation to 41 prevention of mother-to-child transmission programs, medical male circumcision and recent 42 HIV testing. The largest inequalities were reported in condom use, with condom use reported 5 43 times more among the richest versus the poorest (RII=5.02, 95% Confidence interval, CI: 2.79-44 9.05) and in positive attitudes toward PLHIV, with a 32-percentage point difference between the 45 richest and poorest (SII=0.32, 95% CI: 0.26-0.39). Conversely, no significant inequalities were 46 observed in multi-partnership and HIV seropositivity among youth. Overall, inequalities tended 47 to be larger in West and Central vs. East and Southern African countries.

48 Conclusions: Despite efforts to scale-up HIV-prevention programs, socioeconomic inequalities
49 remain substantial over the continuum of HIV primary and secondary prevention in several SSA
50 countries.

51 Introduction

52	Despite a sustained decrease over the last decade, sub-Saharan Africa (SSA) continues to bear a
53	disproportionate burden of the global HIV epidemic, with about two thirds of the worldwide
54	number of HIV infections [1]. Many SSA countries are not on track to meet global targets of 90%
55	reduction of new HIV infections by 2030 compared to 2010 [2,3]. There is however a large body
56	of literature supporting the fact that these targets could be reached by effectively combining
57	existing prevention interventions and tools, including behavioural prevention, condoms,
58	voluntary male medical circumcision (VMMC), pre-exposure prophylaxis (PrEP), HIV testing,
59	and prevention of mother-to-child transmission (PMTCT), alongside increased antiretroviral
60	coverage [4].
61	HIV risk, knowledge and attitudes, access to services and HIV outcomes vary largely across
62	gender, age, location or social status. Inequalities, including socio-economic inequalities, have
63	been recognized as a contributor in the failure to meet the UNAIDS 90-90-90 testing and
64	treatment 2020 targets [5], and may also be a factor in the disappointing progress in effective
65	prevention coverage. Indeed, socio-economic inequalities have been reported across HIV
66	knowledge [6], HIV testing [7–9], PMTCT [10], and VMMC [11]. However, there has not been to
67	date a comprehensive large-scale assessment of socioeconomic inequalities across the major
68	prevention pillars to guide the focus of future programming to overcome current gaps. Such an
69	assessment would be valuable, though. Firstly, it would allow to identify, within the main HIV
70	prevention pillars, those that could potentially be at specific risk of generating socioeconomic
71	inequalities in HIV infections. Secondly, a monitoring of national HIV prevention indicators
72	focusing on inequalities would potentially allow to identify and then learn from settings that are
73	specifically performant in terms of equity.
74	In this paper, we used nationally representative surveys conducted across 18 sub-Saharan

75 African countries between 2010 and 2018 to quantify wealth-related inequalities in several

76 indicators aiming at capturing HIV prevention elements.

77

78 Methods

79 Study population and data

80	We analysed data from the most recent Demographic and Health Surveys (DHS) in 18 Sub-
81	Saharan African countries (based on data availability as of November 2020). The country
82	sample was a convenience sample based, and slightly extended, from an earlier research
83	project [9]. The sample included Burkina Faso, Cameroon, Côte d'Ivoire, the Democratic
84	Republic of Congo (DRC), Ethiopia, Guinea, Kenya, Lesotho, Liberia, Malawi, Mali, Niger,
85	Rwanda, Senegal, Sierra Leone, Tanzania, Zambia, and Zimbabwe.
86	DHS are nationally representative surveys based on a multistage design with households as
87	sampling units. They collect a wide range of demographic and reproduction health indicators
88	among consenting adults that are interviewed face-to-face by trained interviewers using
89	standardized questionnaires [12]. The collected data notably include age and gender, as well
90	as specific data on HIV/AIDS. In particular, some DHS include an HIV serological survey,
91	for which participants are asked to consent to be tested for HIV (anonymously in most of the
92	surveys included here). Household wealth was assessed using the DHS wealth index, a
93	composite measure of living standards that is based on the household's assets (e.g.
94	refrigerators) and characteristics (e.g., sanitation facilities) [13].
95	All DHS were conducted by national central statistics agencies or research institutes. The
96	institutions that approved, implemented, or provided funding for the surveys were responsible
97	for ethical clearance, which guaranteed informed consent and confidentiality of participant's

98 information.

100 HIV indicators

101	We de	fined and analysed a set of eight HIV indicators aimed at capturing HIV knowledge,							
102	attitudes, behaviours and access to and uptake of HIV prevention services. These indicators								
103	were chosen and designed in a pragmatic way based on the information collected in the DHS								
104	across all countries selected for this analysis. These HIV indicators were consistently coded as								
105	binary	variables with the level 1 (the level 0, respectively) reflecting a favourable							
106	(unfav	ourable, respectively) condition regarding HIV. These HIV indicators were:							
107	i)	HIV-related knowledge: based on the responses to a set of seven questions related to							
108		HIV transmission and prevention, we defined a categorical indicator reflecting good							
109		HIV-related knowledge (coded as 1 for those answering all questions correctly, 0							
110		otherwise).							
111	ii)	Positive attitudes towards PLHIV: based on a set of two questions related to stigma							
112		towards PLHIV, we defined a categorical indicator reflecting positive attitudes							
113		towards PLHIV (coded as 1 for those answering positively to both questions, 0							
114		otherwise).							
115	iii)	No multipartnership (no or one sexual partner) in the past year: based on the number							
116		of sexual partners reported in the last 12 months (self-reported, coded as 1 for those							
117		reporting no or one sexual partner, 0 otherwise)							
118	iv)	Condom use at last sexual intercourse (self-reported, coded as 1 for those reporting							
119		having used a condom during their last intercourse, 0 otherwise).							
120	v)	VMMC (among men only): based on the self-reported circumcision status and the							
121		qualification of the person who performed the circumcision (health							
122		worker/professional). We only analysed VMMC in 7 countries among of 14 that have							

been prioritized for the implementation of VMMC as HIV-prevention intervention in

124 2007 (mainly in Eastern and Southern Africa) [14].

- vi) *Participation in Prevention of Mother to Child Transmission* (PMTCT, among women
 only): based on self-reported HIV testing during antenatal care among women who
 gave birth in the 12 months preceding the survey (coded as 1 for those reporting
 having been tested, 0 otherwise).
- vii) *Recent HIV testing*: based on self-reported HIV testing within the past 12 months
 (coded as 1 for those reporting having been recently tested, 0 otherwise).
- 131 viii) HIV seronegativity among youth: based on the result of the HIV serological survey 132 among 15-24 years old participants (coded as 1 in seronegative youths, 0 otherwise). 133 trends in HIV prevalence among youth (aged 15-24 years) have been documented to be a surrogate reflecting trends in HIV incidence [15,16]. As the onset of sexual 134 135 activity in this group is likely to be recent, prevalence reflects recent infection and 136 therefore incidence. We thus used the socioeconomic gradient in HIV seroprevalence 137 among the 15-24 years old as a proxy for the socioeconomic gradient in HIV incidence. To consistently consider a level 1 reflecting a favourable condition and 138 139 therefore facilitate the interpretation and comparison of inequalities across indicators, 140 the level 1 was chosen to code HIV seronegativity.

141 Further details on the construction of these HIV-related indicators are provided in Appendix 1

142

143 Statistical analysis

For each country survey and each HIV indicator, we calculated percentages of positivity
taking into account the survey design and sampling weights. We then assessed within-country
socioeconomic inequalities related to each indicator based on participants' relative rank in the

147	cumulative distribution of the wealth index. Inequalities were measured on both relative and
148	absolute scales using the relative index of inequality (RII) and the slope index of inequality
149	(SII), respectively [17]. The RII expresses the ratio of the predicted outcomes between the
150	richest and the poorest people in the wealth distribution. The SII represents the absolute
151	difference in the predicted proportions of these two extremes. For instance, a RII value of 2
152	indicates that individuals at the upper extreme of the wealth distribution (the richest) are twice
153	more likely to report the outcome than individuals at the lower extreme (the poorest). A SII
154	value of 0.2 means that the proportion of the outcome is higher by 0.2 (or higher by 20
155	percentage-points) in the upper extreme of the wealth distribution (the richest) versus the
156	lower extreme (the poorest). Reporting inequalities on both scales is recommended, because
157	conclusions can be skewed when only one or the other is used [18]. Furthermore, the choice
158	of a relative scale over an absolute scale or vice versa carries an implicit normative judgment
159	on what a fair and socially just distribution of health should be [19].
160	Both RII and SII were obtained by fitting a modified Poisson regression with a robust
161	variance and a log link function to estimate the association between participants' relative
162	wealth rank and each indicator, and by using generalised estimating equations to account for
163	the clustering of observations [20]. We used the Wilcoxon rank-sum test to compare indices
164	of inequalities between West and Central Africa (WCA) versus East and Southern African
165	(ESA) countries (except for VMMC, which was studied in ESA only). Lastly, we used
166	random-effects meta-analysis to average inequality estimates across countries [21].
167	

167

168 Results

169 Study population

- 170 DHS included in the present work were conducted between 2010 and 2018 (Figure 1), with
- 171 participation rates ranging from 90% (Ethiopia 2016) to 100% (Rwanda 2014-15) (Table 1).
- 172 Overall, these studies represented 358,591 participants, (238,055 women and 120,536 men).
- 173
- 174

- 176 Figure 1: Demographic and Health Survey (DHS) year (left) and adult HIV prevalence (right) of the
- 177 **18 Sub-Saharan African countries** (NB: For Kenya, HIV prevalence is unavailable in its last DHS 2014).

Table 1: Distribution of HIV-related indicators for 18 Sub-Saharan African countries (Demographic and Health Surveys). PLHIV: People living with HIV; PMTCT : Prevention
 of Mother-to-Child Transmission; VMMC: Voluntary Medical Male Circumcision; NA: Not Available. ¹: as reported in the country's DHS final report; ²: within the past year; ³: at last sexual intercourse; ⁴: among those aged 15-24 y. Countries are ordered west to east.

181 *HIV indicators*

182	Country-specific percentages of positivity for each HIV indicator are presented in Table 1. In ESA
183	countries, good HIV-related knowledge ranged from 22% (Ethiopia) to 43 % (Rwanda) while it
184	was \leq 20% in 8 out of 10 WCA countries (with the exception of Cameroon, 30% and Burkina
185	Faso, 23%). Similarly, positive attitudes toward PLHIV were >60% in 7 out of 8 ESA countries
186	(with the exception of Ethiopia, 40%) while the highest level in WCA was 55% (Cameroon).
187	Reporting no multipartnership in the past 12 months was consistently high across countries,
188	ranging from 88% (Sierra Leone, Côte d'Ivoire and Lesotho) to 98% (Rwanda and Ethiopia).
189	Reported condom use at last sexual intercourse was highest in Lesotho (51%). In other
190	countries reported condom use was lower, ranging from 1% (Niger) to 23% (Zimbabwe).
191	Overall, higher uptake of HIV testing in the past 12 months was observed in ESA, with uptake
192	>20% in all countries, as compared to in WCA, where uptake was <20% in 9 out of 10 countries.
193	Similarly, ESA countries reported levels of participation to PMTCT >95% in 6 out of 8 countries
194	(with the exception of Ethiopia, 57% and Tanzania, 81%), while it was <90% in all WCA
195	countries, with large heterogeneity (from 23% in Mali to 89% in Cameroon). As mentioned
196	earlier, VMMC was reported in ESA countries only, with levels ranging from 9% (Malawi) to 85%
197	(Rwanda).

198

199 Socioeconomic inequalities in the HIV indicators

200 Measures of relative and absolute inequalities pooled across countries are presented in Table 2.

201 Significant levels of relative and absolute inequalities in favour of the richest were observed for

202 HIV-related knowledge, positive attitudes toward PLHIV, condom use at last sex, participation to

203 PMTCT, VMMC and recent HIV testing. In contrast, we observed inequalities in the other

204 direction in reporting no multipartnership and in HIV-seronegativity among youth (that is, the

205 poorest reported lower levels of multipartnership and exhibited lower levels of HIV

seropositivity), although these inequalities were borderline significant and of low magnitude as

207 compared to the other indicators. The ranking of the indicators by level of inequalities varied 208 between the relative and the absolute scales. On the relative scale, the highest level was 209 observed for condom use, with the richest being approximatively 5 times more likely (RII = 5.02; 210 95 Confidence interval, CI, 2.79-9.05) to use condom than the poorest people. In the absolute 211 scales, the largest gap between the richest and the poorest people was observed in positive 212 attitudes toward PLHIV, with a difference of 32 percentage-points (SII=0.32; 95% CI 0.26-0.39). 213 On the relative scale, levels of inequalities were significantly higher in WCA as compared to ESA 214 countries for the following indicators: HIV-related knowledge, positive attitude towards PLHIV, 215 condom use, participation to PMTCT and recent HIV testing (all rank-sum test p-values <0.05). 216 Absolute levels of inequalities were also higher in WCA versus ESA countries for participation to 217 PMTCT (0.43 versus 0.12, respectively, p=0.009) and for recent HIV testing, although this was 218 borderline significant (0.16 versus 0.09, respectively, p=0.06). 219 A more detailed comparison of the levels of inequalities across indicators and across countries is 220 displayed in Figure 2. In WCA countries, the countries exhibiting the higher levels of inequalities 221 were generally not the same when considering the relative or the absolute scale. In contrast, in 222 ESA countries. Ethiopia tended to exhibit the highest levels of inequalities on both the relative 223 and absolute scales. We also observed significant inequalities in favour of the poor in HIVseronegativity among youth in some countries, especially on the absolute scale (for example in 224 225 Sierra Leone, Zambia, Rwanda), although their magnitudes were lower than for other indicators. 226 Table 3 presents the correlations between RII (log-transformed) and SII values across HIV-227 related indicators. We observed significant positive correlations between relative- and absolute 228 inequalities metrics for most of the indicators (Pearson correlation coefficients >0.6 in 6 out of 8 229 indicators), apart from condom use and VMMC presenting no evidence of correlation.

230

257

258 DISCUSSION

259 In this study, relying on cross-sectional population-based surveys, we provide an extensive

assessment of socio-economic inequalities in various HIV indicators capturing knowledge,

attitudes, behaviours and access to and uptake of prevention services in a large set of sub-

262 Saharan African countries. We document important levels of wealth-related inequalities, both on

the relative and absolute scales, in HIV-related knowledge, positive attitudes toward PLHIV,

264 condom use, participation to PMTCT, uptake of VMMC and recent HIV testing. The magnitude of

these inequalities varies across countries and indicators. However, inequalities tend to be more

266 marked in WCA than in ESA countries. In contrast, we document low overall levels of

267 inequalities in multi-partnership and HIV seropositivity among youth, a surrogate of HIV

268 incidence.

269 The arithmetic behind inequality measures

270 The results we provide here allow two types of comparisons: cross-country comparisons of

271 inequalities given a specific HIV indicator, and within-country comparisons of inequalities

272 across HIV indicators. However, first bearing in mind some arithmetic considerations is 273 important when comparing RII and SII across indicators and countries [22,23]. Indeed, for any 274 indicator, the overall level in the population should be considered when interpreting relative 275 and absolute inequalities measures. Relative inequalities tend to be larger at low overall levels 276 of the considered indicator, while absolute inequalities tend to be larger at intermediate levels. 277 This arithmetic explains, for instance, why condom use in Niger (overall self-reported level: 278 1.1%) acknowledges dramatic relative inequalities (RII >100) but relatively limited absolute 279 inequalities (SII = 0.07). This illustrates the importance of reporting both relative and absolute 280 measures when reporting inequalities, as conclusions would be quite different if based on only 281 one or the other indicators in this single example. However, our analysis of correlation showed 282 that the levels of inequalities tended to correlate across both scales for most of the indicators we 283 used.

284 Cross-country comparisons of inequalities

285 Heterogeneity across countries regarding the inequalities reported here may be driven by a 286 potentially large spectrum of socioeconomic, epidemiological or healthcare-related factors. 287 Nevertheless, we observed that geography explained some of this heterogeneity: higher levels of 288 wealth-related inequalities were observed in countries in WCA compared to those in ESA, 289 especially on the relative scale. Several factors may explain higher levels of inequalities in WCA. 290 This may be related to the historical prominence of the private healthcare sector in this region, 291 which generally implies user fees that may act as a barrier to access to care for the poorest [24]. 292 Higher levels of inequalities are also possibly linked to the smaller overall HIV epidemics in WCA 293 compared to ESA. Indeed, ESA countries had higher HIV prevalence than WCA countries in our 294 sample, except for Ethiopia, which precisely had the highest levels of wealth-related inequalities 295 within ESA countries. Previous results suggested that HIV-related inequalities correlated with 296 epidemiological rather than macro-economic factors [25]. In addition, the country-level HIV 297 prevalence has been reported to correlate with levels of HIV donor and national funding for HIV

prevention services [26]. Moreover, donor funding tended to prioritise prevention programs
targeting key populations in WCA, as new HIV infections are often predominantly in these
populations in the region, whilst in ESA HIV prevention efforts are broader encompassing both
key populations and the general populations [27]. While key populations deserve a priority
focus for HIV prevention in WCA, additional efforts should be considered to overcome the
socioeconomic disparities in knowledge and access to HIV testing and prevention services more
broadly.

305 Comparisons of inequalities across HIV indicators

306 Overall, we did not observe large socioeconomic disparities in reporting having multiple sexual 307 partners, consistently with recent results [28]. Large absolute and relative inequalities, overall, 308 remain regarding lack of knowledge and stigmatizing attitudes toward PLHIV, and this may 309 undermine HIV prevention, care and treatment [29]. Concerning inequalities are observed in 310 condom use, PMTCT, VMMC and HIV testing, especially in WCA countries. This is of particular 311 concern because these are interventions that can prevent new infections, directly for condom 312 use and VMMC, or when linked to care and treatment for PMTCT and HIV testing. Large 313 inequalities in condom use may reflect difficulties to access condoms free of charge. However, 314 PMTCT, VMMC and HIV testing are also interventions that are usually provided at no direct cost 315 for the individual, which underlines that providing these services without cost to clients is not 316 the only factor to ensure equitable access to prevention interventions. Lessons should be drawn 317 from the experiences of PMTCT or HIV testing programs in ESA countries that are currently 318 offered to all at no cost, without producing measurable health inequalities. For instance, Rwanda 319 has successfully integrated HIV services within the existing healthy system and assured delivery 320 of services in remote areas. These strategy have strengthened the country response to HIV and 321 have most probably contributed to limiting health inequalities [30].

322 Contrary to what one could expect considering the inequalities disfavouring the poorest in terms323 of access to HIV prevention service that we report here, we did not find any evidence of

324 socioeconomic inequalities regarding HIV prevalence among the youth, an indicator we used as 325 a proxy for HIV incidence. This apparently inconsistent result may however be linked to the 326 complex and changing social epidemiology of HIV. Many early studies reported that higher SEP 327 tended to be associated with a higher prevalence of HIV infection, making this distribution 328 unusual as compared to many health outcomes [31,32]. The absence of overall socioeconomic 329 gradient we report here may represent a transient state were inequalities are inversing, from a 330 higher risk for the wealthiest to a higher risk for the poorest [33,34]. Indeed, a recent study 331 relying on a >20-years follow-up among a population-based open cohort in rural Uganda 332 documented a widening socioeconomic gradient over time, with a higher risk of incident HIV 333 infection among the poorest [35]. An effort to more systematically monitor socio-economic 334 inequalities in HIV incidence is thus of high importance to detect possibly changing SEP 335 gradients. It is anticipated that the newer-generation surveys, such as the population-based HIV 336 impact assessment surveys (https://phia.icap.columbia.edu/) which integrate HIV incidence 337 assays, may provide useful data for this monitoring.

338 Main strengths and limitations of the study

339 This study has several limitations and strengths. The between-country comparison may be 340 affected by the period of data collection for each national survey (from 2010 to 2018). Large HIV 341 programs have been implemented over this study period and may have reduced inequalities 342 over time [9]. Our analysis was limited to indicators pragmatically built on data collected as part 343 of the DHS. As such, it matches only partially the recently proposed unifying framework of the 344 HIV prevention cascade [36]. For instance, an important aspect absent from the DHS data, and 345 therefore from our analysis, relates to knowledge and use of antiretroviral treatment for 346 individual and collective health benefits. For the same reason, our analysis ignores important 347 prevention interventions, such as pre-exposure prophylaxis (PrEP), or interventions targeted to 348 key populations. However, to our knowledge, this study constitutes the first effort to quantify

349	both relative an	d absolute s	ocioeconomic i	inequalities on a	large set of HIV	V-related indicators

350 collected from large, representative surveys conducted in numerous SSA countries.

351 Conclusions

- 352 In conclusion, this study provides a comprehensive monitoring of socioeconomic inequalities in
- 353 HIV knowledge, attitudes, behaviours and prevention in sub-Saharan Africa. In other fields such
- as child health, such monitoring has provided important insight in the way policies may be
- tailored to the patterns of inequalities in order to best address them [37]. We hope that this
- 356 study will help in the strategical articulation of HIV prevention approaches that is required for
- 357 fulfilling the focus on reducing inequalities that the renewed 2021-2026 Global AIDS Strategy
- 358 adopted [38].

359

360 Authors' contributions

- 361 MH, PAA-T and KJ conceived and planned the study with input from LT. MH and PAA-T collated
- 362 and processed DHS data. MH and KJ conducted the analysis and produced output figures and
- tables with input from PAA-T and LT. All authors contributed to the interpretation of the results.
- 364 MH and KJ wrote the first draft of the report and all authors contributed to subsequent revisions.
