23

24 **Abstract**

25 **Background:** Core patient characteristic sets (CPCS) are increasingly developed to identify
26 variables that should be reported to describe the target population of epidemiological studies in the
27 same medical area, while keeping the additional burden on the data collection acceptable.

28 **Methods:** We conduct a systematic review of primary studies/ protocols published aiming to develop
29 CPCS, using the PubMed database. We particularly focus on the study design and the characteristics
30 of the proposed CPCS. Quality of Delphi studies was assessed by a tool proposed in the literature.
31 All results are reported descriptively.

32 **Results:** Among 23 eligible studies, Delphi survey is the most frequently used technique to obtain
33 consensus in CPCS development (69.6%, n=16). Most studies do not include patients as
34 stakeholders. The final CPCS rarely include socioeconomic factors. 60.9% (n=14) and 31.6% (n=6)
35 of studies provide definition and recommend measurement methods for items, respectively.

36 **Conclusion:** This study identified a considerable variation and suboptimality in many
37 methodological aspects of CPCS studies. To enhance the credibility and adoption of CPCS, a
38 standard for conducting and reporting CPCS studies is warranted.

39 **Funding:** No funds, grants, or other support were received during the preparation of this manuscript.

40 **Registration:** This review was not pre-registered.

44 **Introduction**

45 In epidemiological research, collecting and reporting patient characteristics are of crucial
46 importance. These data allow one to assess the generalizability (or external validity) of the obtained
47 findings, by looking at how closely the study samples match patients in a realistic healthcare setting
48 (1). When comprehensive patient characteristics data are available, the difference between a study
49 sample and a clinically relevant patient population can even be statistically accounted for, to improve
50 the applicability of the findings in clinical practice (2).

51 Beyond external validity, patient characteristic data is also helpful to improve internal
52 validity. For instance, by assessing the balance of important outcome prognostic factors across
53 different treatment groups in a trial, one can assess whether there might be imperfect randomization.
54 This is highly important when trials are of small sample size (such as in cancerology, where
55 algorithms like minimization-based methods are often used to determine the treatment assignment
56 for each patient) or trials with specific design (such as clusters randomized) (3, 4). In pragmatic trials,
57 detailed patient characteristic data is also strongly needed to account for adherence and drop-out,
58 especially when the aim is to estimate per-protocol treatment effects or to handle missing data (5).
59 Likewise, in observational studies, assessing the balance of exposure and non-exposure groups after
60 propensity score-based stratification or matching, for instance, require extensive data on patient
61 characteristics (6).

62 In systematic reviews and evidence synthesis, when the eligible studies collect and report
63 data on a common set of patient characteristics, the assessment of the target population (factor P in
64 the PICO criteria) across studies will be facilitated. A more insightful evaluation of the heterogeneity
65 observed among trial results will also be possible (7, 8). Recently, novel methods for causally
66 interpretable meta-analysis have been proposed (8-11). These frameworks also rely on having a rich
67 set of (prognostic) patient characteristics collected across individual studies.

68 Despite its importance in practice, the collection and reporting of patient characteristic data
69 remains inconsistent and suboptimal. Cahan et al (2017) recently showed that among 186,941 trials
70 on ClinicalTrials.gov, only 8.9% reported baseline participant measures, and up to 85% of those
71 measures were reported only once in the entire registry (12). Lack of adequate reporting of important
72 prognostic factors was also highlighted by Wertli et al. (2013), when they assessed 84 low back pain
73 trials and found that almost half of them incompletely reported variables that are of prognostic
74 importance, even with easily obtainable variables such as age or comorbidities (13). Similar issues
75 also prevalent in many other medical fields, including asthma, diabetes, hypertension, or colorectal
76 cancer (14-18).

77 In these recent years, significant efforts have been made to standardize the collection and
78 reporting of patient characteristics in epidemiological research. Across many therapeutic areas, a so-
79 called core patient characteristic set (CPCS) is specifically developed to identify all key prognostic
80 factors that should be commonly collected and reported (among studies and databases evaluating a

81 target medical condition), while keeping the additional burden on the implementation acceptable
 82 (Fig. 1). Above and beyond the variables proposed in the core set, researchers are free to measure
 83 and report additional patient characteristics that are of relevance to their topic. This CPCS concept
 84 is inspired by (and hence closely related to) the concept of core outcome set (COS) proposed in
 85 clinical research. However, while the methodology for COS development is increasingly enriched in
 86 the literature, little attention has been given so far to CPCS and how to develop it in practice.

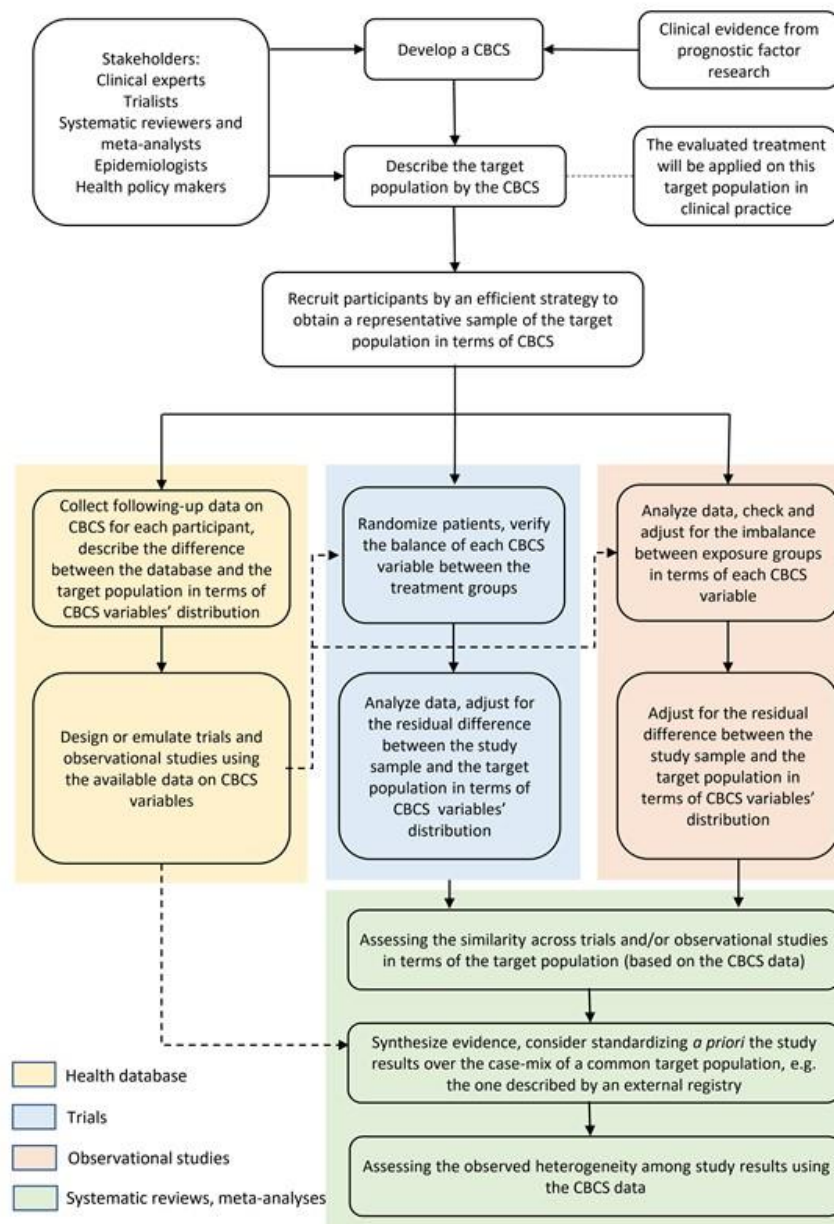

Fig. 1. The use of core patient characteristic sets in epidemiological research

In this paper, we aim to describe the methodology of studies aiming to establish a core set of patient characteristics that should be commonly measured and reported in epidemiological studies and/or in large medical cohorts. By shedding light on current practice and challenges in CPCS

93 development, this review could pave the way for future recommendations and guidelines on
94 methodological standards of CPCS, thus enhancing the adoption of this concept in epidemiological
95 research.

96

97 **Methods**

98 **Study design**

99 We conduct a methodological systematic review conforming to Preferred Reporting Items
100 for Systematic Reviews and Meta-Analyses (PRISMA) 2020 statement (19).

101

102 **Eligibility criteria**

103 We include primary studies or study protocols that aim to establish a core set of patient
104 characteristics that should be commonly measured and reported in epidemiological studies and/or
105 databases of a pre-specified medical condition, published between 01/01/2001 and 11/08/2022. We
106 thus exclude studies that establish patient characteristics sets for other purposes such as to guide
107 therapeutic decision-making in clinical practice. Conference abstracts, editorials, commentaries, and
108 letters to the editor are excluded. Non-English publications and articles without full text accessible
109 are also excluded from our review.

110

111 **Search strategy**

112 A structured search in the PubMed database is undertaken by P.H.T. Tu on 12/08/2022. The
113 full search strategy is available in Appendix S1. This search strategy is first developed by two
114 reviewers (P.H.T. Tu and K.L. Duong), then further optimized by a senior researcher (T.-T. Vo) and
115 a librarian specialized in epidemiological systematic reviews. We also manually screened the
116 reference lists of the eligible articles to identify additional eligible studies.

117

118 **Study selection**

119 The search results are downloaded into Endnote and imported into Rayyan web-based
120 software (20). Duplicates are removed by the duplicate search function in Endnote and by manually
121 reviewing the records list. Four reviewers (P.H.T. Tu, K.L. Duong, M.L. Vuong and T.H.T. Nguyen)
122 independently screen titles and abstracts of retrieved records to select eligible papers based on the
123 inclusion criteria. Each reviewer screens 25% of the total number of records and double-checks 20%
124 of the work of another reviewer. Disagreements are resolved by discussion among four reviewers,
125 and consultation with a senior researcher (T.-T. Vo).

126

127 **Data extraction and assessment**

128 The data extraction form is developed by M.L. Vuong and P.H.T. Tu, pilot-tested and refined
129 by K.L. Duong and T.-T. Vo (Appendix S2). The structure of the data extraction form is partially
130 adapted from Boukdedid et al (2011) and Diamond et al (2014) (21, 22). Data extraction is performed
131 by M.L. Vuong, P.H.T. Tu and K.L. Duong. Each reviewer extracts 33% and double-checks 33% of
132 the total number of records. Any discrepancy is resolved by discussing among the three reviewers.

133 We extract the following information from the eligible studies: [1] publication year, [2]
134 target medical conditions, [3] purposes of the developed CPCS (to use in epidemiological studies or
135 in registry settings), [4] study design (consensus-reaching or non-consensus methods), and [5]
136 geographical scope of the study (international or national-wide).

137 As Delphi technique is the most frequently used method among the eligible studies, we
138 evaluate the methodological and reporting quality of Delphi studies with greater thoroughness. The
139 following characteristics of Delphi studies are extracted: [1] study participants (number, response
140 rate, types, selection criteria of participants, and whether authors report how representativeness of
141 participants is ensured), [2] method to establish the primary list of items before Delphi rounds, [3.1]
142 questionnaire round characteristics: number of rounds, purpose of each round, questions formulation
143 (rating scale or open question), whether the rating scale (if used) is well-defined (i.e. number and the
144 meaning of levels in the scales are specified), whether the questionnaire's content is publicly
145 available and is piloted in advance, summary information sent to respondents after each round, and
146 methods used to encourage participants to complete the questionnaires, [3.2] in-person meetings
147 characteristics: number of meetings and purposes, form of rating scale (if used) and whether the
148 rating scale is well-defined, whether participants from questionnaire rounds are all invited to the
149 meetings or only selectively, and the timing of meetings, [3.3] whether new items are allowed to be
150 added between rounds, and [4] how consensus are defined and attained, and how Delphi process is
151 terminated.

152 In the absence of a standardized, validated quality scores for Delphi studies, we roughly
153 assess the quality of those studies by using the checklist proposed by Diamond et al (2014) (22). Four
154 items in the checklists include [1] the reproducibility of criteria for participant selection and whether
155 [2] the number of Delphi rounds, [3] the criteria for dropping items at each round and [4] the criteria
156 to stop the Delphi process are stated and prespecified. The number of items satisfied in each Delphi
157 study is then reported as quality score. Three reviewers (M.L. Vuong, P.H.T. Tu and K.L. Duong)
158 independently assess the quality of all Delphi studies by this tool and reach final consensus.

159 For the remaining studies, we narratively describe the study design, number and type of
160 participants and organization among them, and method to establish the final CPCS. With non-Delphi,
161 consensus-reaching study, we also extract information on method to establish the primary list of
162 items and the definition and attainment of consensus.

163 Finally, we extract details of the final CPCS obtained. These include, [1] whether description
 164 of item flow reported, [2] whether only the final set or also intermediate results were reported, [3]
 165 whether the items in the final set were ranked and how, [4] number of items in the final set, [5]
 166 whether the definition and measurement of included items were given and [6] domains of items in
 167 the CPCS (demographic, clinical, patient history, socioeconomic or healthcare setting factors).

168
 169 **Data synthesis**

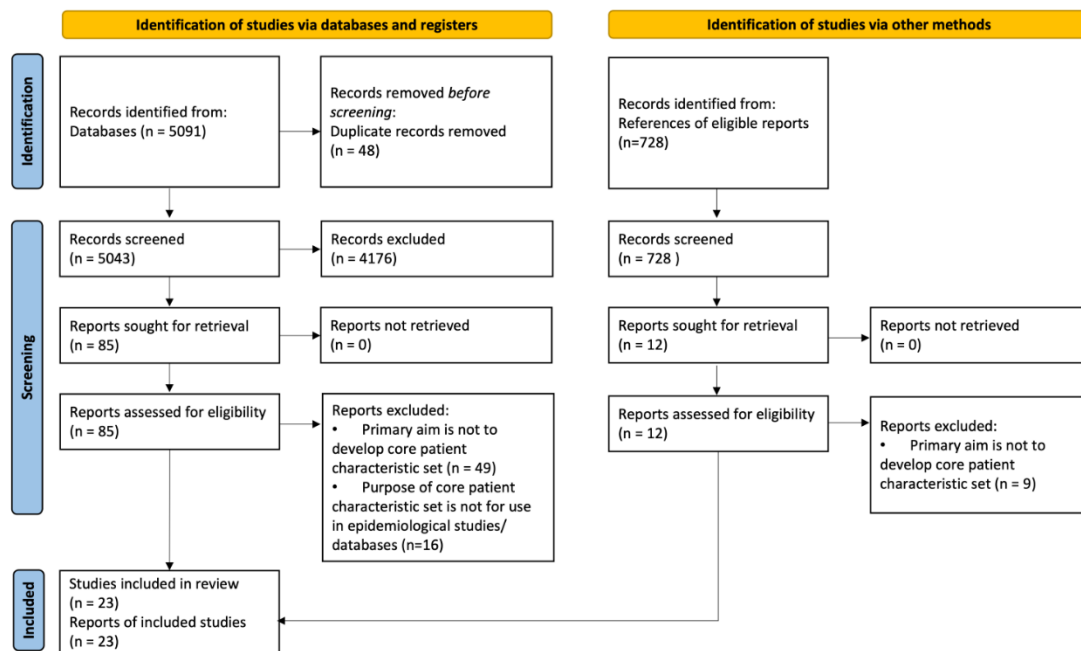

170 Continuous variables were presented with median and interquartile range. Categorical
 171 variables were summarized with frequencies and percentages. To investigate the content pattern of
 172 the final lists of items across eligible studies, we performed a hierarchical, complete-linkage
 173 clustering analysis (23). For each final list, we first calculate the percentage of each domain. The
 174 domain profile for each study was then used to calculate the matrix of between-study Euclidean
 175 distances. Finally, the obtained result was visualized by a tree-structure graphic.

176 Data analysis was performed using Microsoft Excel 365 and R version 4.1.1.

177 **Results**

178 **Study selection**

179 The PRISMA flow diagram summarizing the screening process is presented in **Fig. 2**. Of all
 180 5819 references identified, 23 articles met the inclusion criteria for review.

181

PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses

186 **General characteristic of included studies**

187 The general characteristics of all the studies included (24-42) are provided in Table 1.
188 Among 23 eligible studies, 73.9% (n=17) develop a CPCS for epidemiological studies, 21.7% (n=5)
189 develop such a set for healthcare registries and one study (4.3%) develops a CPCS for both registries
190 and epidemiological studies. About 91% of studies (n=21) were published in the last ten years, and
191 78.3% of studies (n=18) has an international scope. Regarding methodology, 87.0% of studies (n=20)
192 consider a consensus reaching method to develop the core set, with Delphi being the most frequently
193 used technique (69.6%, n=16). Other non-consensus methods include systematic review (8.7%, n=2)
194 and conceptual analysis (4.3%, n=1).
195

- National-wide	1	4.3
- Not reported	4	17.4

^a Including burns, chronic fatigue syndrome, rehabilitation, and hemophilia.

198

199 **Methodological characteristics of Delphi studies**

200 The methodological characteristics of 16 eligible Delphi studies are provided in Table 2
201 and Appendix S3. Remarkably, almost all studies involve healthcare professionals (93.8%, n=15) or
202 researchers (81.3%, n=13), while only one study (8.3%) involves patients or patient representatives.
203 The criteria for selecting participants are quite various across studies, but most commonly based on
204 scientific renown, publishing and/or expertise level (58.3%, n=7). Though the acceptance rate of the
205 eligible studies is relatively low (median of 25 participants versus 40 invitations), only 41.7% of
206 studies (n=5) reported how they ensured the representativeness of participants.

207 Across all studies (100%, n=12), rating scales are used to judge the importance of items
208 during the questionnaire rounds. These scales range from two-point to ten-point, with five-point
209 scales being the most commonly used (33.3%, n=4). The scale is deemed as well-defined in 83.3%

210 of studies (n=10). Apart from item rating, open-ended questions are also included in 66.7% of studies
211 (n=8), mostly to collect qualitative feedback from participants (58.3%, n=7). Besides, 41.7% of
212 studies (n=5) report the use of a specific method to encourage participants to complete the
213 questionnaires (e.g., by sending them reminders or vouchers).

214 In six (modified) Delphi studies, in-person meetings or teleconferences are additionally
215 organized. The median number of meetings is two (IQR 1–4). The aim of these meetings is to have
216 discussions among participants before rerating the existing items (41.6%, n=5) and adding new items
217 (8.3%, n=1). The rating scales used in these meeting rounds are mainly binary scales (25.0%, n=3),
218 and are well-defined in four studies (33.3%). Meetings are scheduled at different timepoints, either
219 before (8.3%, n=1), in between (25.0%, n=3) or after the questionnaire rounds (16.7%, n=2).

220 Finally, 16.7% of studies (n=2) do not report the criteria for selecting or dropping an item
221 (Appendix S3). In 91.7% of studies (n=11), the Delphi process is terminated when the preplanned
222 rounds are completed, regardless of the stability of responses or whether consensus has been obtained
223 for all items. In one study, the reason for termination is unclear. As stopping the Delphi not based on
224 response stability or consensus is deemed as suboptimal (22), all studies are penalized for this in the
225 subsequent quality assessment. More precisely, 50% (n=6) of studies have a quality score of three,
226 and 50% (n=6) of studies have a quality score of one or two, on the four-point quality scoring system
227 proposed by Diamond et al. (2014) (22) (Appendix S3).

228

229 **Table 2** – Methodological characteristics of studies using Delphi consensus approaches (N=16)

Methodological characteristics	N	%
1. Participants		
Type of stakeholders ^a		
• Healthcare professionals	15	93.8
• Researchers, including clinical trialists, epidemiologists, statisticians, and/or public health experts	13	81.3
• Data or registry/program managers	3	18.8
• Policy makers	2	12.5
• Insurance experts	2	12.5
• Patient representatives	1	6.3
The study reports how representativeness of participants is ensured	6	37.5
2. Delphi rounds		
2.1. Questionnaire rounds (in all 16 Delphi studies)		
Number of rounds, median [IQR]		2.5 [2–4]
Question formulation		
• Rating scale for each item	16	100.0
○ Binary scale	2	12.5
○ Likert scale	3	18.8
○ Unclear scale format	1	6.3
• Open questions in addition to rating scale	10	62.5
Rating scale/score well defined	14	87.5
2.2. In-person/teleconference meeting rounds (in 8 modified Delphi studies)		
Number of rounds, median [IQR]		2 [1–3]
Rating scale formulation	7	43.8
• Binary scale	5	31.3
• Six-point Likert scale	1	6.3
• Unclear scale format	1	6.3
Rating scale/ score well defined	4	25.0
3. Consensus definition and attainment		
Criteria for selecting/dropping items at each round based on:		
• (i) Pre-defined cut-off(s) of % of participants voting certain rating level(s)	9	56.3
• (ii) Pre-defined cut-off(s) of a median score on a rating scale	1	6.3
• Both (i) and (ii)	4	25.0
• Unclear/ not reported	2	12.5
Reason to terminate Delphi process		
• After completing the number of rounds prespecified	14	87.5
• When consensus is reached	1	6.3
• Unclear	1	6.3

^a Each study may be classified in more than one category; IQR: interquartile range.

230

231

232

233 **Methodological characteristics of non-Delphi studies**

234 The methodological characteristics of seven non-Delphi studies are provided in Table 3. In
 235 general, only one study (14.3%) reports the types of stakeholders participating in the construction of
 236 the CPCS, and no studies report number nor distribution of stakeholders. Similarly, no studies report
 237 the criteria for selecting/dropping each item, neither how consensus is reached after each round and
 238 at the end.

NDC: non-Delphi consensus, SR: systematic review, CA: conceptual analysis

243 Characteristics of the final lists of patient characteristics

244 The reporting of results and characteristics of the final CPCSs are provided in Table 4 and
245 **Fig. 3**. Almost all studies (91.3%, n=21) report the final CPCS. Studies that develop a CPCS for in
246 registries often have more items than those developing a CPCS for epidemiological studies (26 [10-
247 31] vs 17 [10-23]) (Table 4).

248 The characteristics of the final CPCSs is provided in **Fig. 3**. Most CPCSs contain
249 demographic factors (age, gender, race), clinical factors (e.g., disease severity, presence of a
250 symptom, laboratory test) and patient history factors (e.g., lifestyle, comorbidities, family history).
251 In contrast, socioeconomic factors and healthcare settings factors are often absent in most final lists.

252 Items included are defined in 60.9% of CPCS (n=14). Besides, 34.8% (n=8) and 26.1% (n=6)
253 of CPCS have specific recommendations on the scale and measurement method for non-obvious
254 items, respectively (Table 4).

255

256

257 **Fig. 3.** Hierarchical clustering of 21/23 CPCS based on five variable domains, namely [1]
258 Demographic factors (age, gender, race), [2] Clinical factors (e.g., disease severity, signs and
259 symptoms, laboratory test), [3] Patient history factors (e.g., lifestyle factors, comorbidities, family
260 history), [4] Socioeconomic factors (e.g., level of education, income, occupation), [5] Healthcare
261 setting factors (e.g., ambulatory care, inpatient, or ICU). Each slice of the chart represents one CPCS.

262 The sectors in each chart indicate what type of variables were included in each CPCS, with the area
 263 of each sector corresponds to the proportion of each variable type within one CPCS. For instance,
 264 the CPCS developed by Khalil et al. (2019) consists of two variable domains: demographic factors
 265 and patient history factors, which make up 25% and 75% of the CPCS, respectively. The blue lines
 266 starting from the center of the chart define how the tools are divided into the six clusters. Clusters #3
 267 and #4, and #5 and #6 are grouped as sub-nodes of two major nodes, meaning that the tools in these
 268 sub-nodes have more similar domain profile compared to the tools in other clusters.

Discussion

274 The call for better patient characteristics collection and reporting in epidemiological research
 275 is not new. The Consolidated Standards of Reporting Trials (CONSORT) statement is one of the first
 276 initiatives aiming to improve the reporting of trials, including the selection criteria (item 4a) and the
 277 description of the resulting samples (item 15). A table showing baseline demographic and clinical
 278 characteristics for each treatment group, including the baseline measurement of the outcome is
 279 required. However, the CONSORT statement provides no further indication of which patient
 280 characteristics to report. Extensions of the CONSORT statement specify that information on
 281 socioeconomic variables should be added, and that all relevant prognostic variables should be
 282 reported, but only one CONSORT extension explicitly asks to include comorbidity. Another
 283 initiative is the Food and Drug Administration Amendments Act (FDAAA) mandates which require
 284 all covered studies to report results (including participants' age, gender, race or ethnicity, and the
 285 baseline measures of the primary outcome) within 1 year of completion (43).

286 Constructing core patient characteristics sets is increasingly considered as a new method to
 287 further improve the collection and reporting of patient characteristics. Most CPCSs are developed
 288 within the last ten years. Not only for improving internal and external validity of epidemiological

289 studies, many CPCSs are also developed to increase the quality of patient characteristics data in
290 registries. This is essential because registries are becoming important data sources for recent
291 epidemiological research.

292 In this review, we identify many different methods to construct a CPCS. Among these
293 methods, consensus-reaching techniques such as Delphi survey are the most frequently used. Indeed,
294 Delphi survey is one of the ideal methods to collect expert-based judgements when the available
295 knowledge is incomplete, which is often the case in CPCS or COS development (44).

296 Most Delphi studies in our review do not include patients as stakeholders. This is probably
297 because CPCS development requires specialized knowledge on prognostic factors of a certain
298 disease. Hence, involving patients would bring little benefit to the process. However, embracing
299 patients' perspective on certain variables in the final set could be helpful, especially when these
300 variables are private information of patients such as socioeconomic status, income, family history
301 etc. Methods for patient engagement has recently been proposed for core outcome set, which could
302 be further adjusted for the development of CPCS (45, 46). Besides, many CPCS studies do not report
303 how the representativeness of participants is ensured. Such information is important to determine the
304 quality of the obtained CPCS and its uptake, hence should be better reported in future practice.

305 Our review has identified a wide range of consensus definitions employed by Delphi studies,
306 with the most common definitions based on the pre-defined cut-offs of percentage of participants
307 voting certain rating levels. This is in line with findings from previous reviews (22, 47). Earlier
308 studies also acknowledged the difficulty of ascertaining the validity of consensus definitions, and
309 there has been no specific guidance on best consensus definition method, which could explain the
310 observed variability in our study (22). However, the minimum standard is to report comprehensibly
311 how consensus is defined and achieved throughout the process. This is not satisfied by one-sixth of
312 eligible studies. Lack of clarity on this could render the studies susceptible to bias and arbitrariness
313 during data collection, analysis and interpretation (47).

314 Most of studies stop the Delphi process after completing a prespecified number of rounds,
315 regardless of the consensus attainment status. Considering the scarcity and/or divergence of evidence,
316 perfect consensus for 100% of items may not be achievable. Indeed, it has been shown that the
317 evidence of many prognostic variables greatly suffers from a high risk of publication bias, selective
318 reporting biases, poor statistical analyses and so forth (48). To compromise on this issue, many CPCS
319 studies choose to group items into different sets with different priority (based on level of evidence
320 and/or consensus), so that researchers will also be informed about the quality of the variables in the
321 final set. On the other hand, it is important to update the CPCS over time when novel evidence for
322 new (and current) prognostic factors are available in the literature.

323 Regarding non-Delphi studies, the methodological reporting is relatively weak. Many
324 important factors such as characteristics of experts, method to establish the final list and consensus

325 attainment were often not reported. This raises concern about the rigor of the CPCSs obtained from
326 these studies.

327 Our review also provides many important remarks on the final core sets across studies. First,
328 while demographic, clinical and patient history factors are dominant in all final sets, socioeconomic
329 and healthcare setting factors are often overlooked. This is suboptimal. Indeed, the socioeconomic
330 gradient in health is ubiquitous, and has been described across pathologies, in life expectancy and
331 mortality (49-51). Meanwhile, describing the healthcare setting is important to assess the
332 applicability of any epidemiological findings into practice. These two types of factors are not any
333 less important than other clinical factors often included in the CPCSs.

334 Second, the number of (final) items in CPCSs for registries is often higher than in CPCS for
335 epidemiological studies. This could be because registries are of large scale and have more (financial
336 and human) resources for data collection than in traditional epidemiological research (41). The
337 disparity between CPCS for registries and epidemiological studies, however, could imply the
338 challenges in the interoperability between these two settings, and the adoption of CPCS from one
339 setting to the other within one medical field.

340 Finally, apart from a list of important patient characteristics to collect and report, many
341 CPCSs also provide recommendations on the measurement methods and scales for non-obvious or
342 subjective items. Doing so could further reduce the heterogeneity and inconsistency in data collection
343 practice, as the conversion between different scales for many variables is not straightforward. The
344 downside of this, however, could be that the applicability of the proposed CPCS is reduced in
345 practice. For instance, the recommended measurement methods might be not widely used or have a
346 high cost. These practical factors should be taken into account when making recommendations on
347 the core set.

348 It is important to acknowledge some limitations of our study. First, we limited the eligibility
349 criteria to articles published in English, hence appropriate studies that were not published in English
350 might have been excluded. Second, the great difference between the number of records identified
351 from the literature and the number of eligible studies may arise from the fact that the specificity and
352 coverage of our search strategy is not optimal. Such a challenge stems from the discrepancies and
353 non-standardized terminology for CPCS, as opposed to COS. We mitigate this issue by consulting a
354 librarian specialized in epidemiological systematic reviews to optimize the search strategy, and by
355 manually search for additional eligible studies from the reference list of identified eligible studies.
356 Finally, we were not able to conduct a formal quality assessment for Delphi studies nor CPCS studies
357 in general, as tools for such purpose are not yet available in the literature.

358

359 **Conclusion**

360 This methodological systematic review has revealed the suboptimality of the conduct and
361 reporting of CPCS studies, particularly in participant characteristics, method to obtain the final

362 CPCS, and coverage and detail of the CPCS obtained. A conduct and reporting standard for CPCS
363 studies is thus warranted, to further enhance the quality of CPCSs and promote the adoption of this
364 concept in epidemiological research.

366

367 **Declarations**

368 **Ethics approval**

369 Our study results were based on previously published data, none of which is stated as research
370 involving human or animal subjects. Ethical approval is thus not required.

371 **Data and computing code availability**

372 All data extracted for the systematic review and R code are made available as supplementary
373 information (Appendix S4&S5).

374 **Funding**

375 *The authors received no financial support for the research, authorship, and/or publication of this*
376 *article.*

377 **Registration and protocol**

378 This review includes no clinical studies and therefore no protocol was pre-registered.

379 **Conflicting Interests**

380 The Authors declare that there is no conflict of interest.
