Translational relevance

1 High lymphocytic infiltration (TILs) seem to reflect favorable host antitumor immune
2 responses. In breast cancer, the variation of TILs before and after neoadjuvant chemotherapy
3 (NAC) according to *BRCA* status has been poorly described. Little data is available on their
4 value after treatment. We investigated TIL levels before and after NAC and response to
5 treatment in 267 paired biopsy and surgical specimens.

6 In our study, luminal BCs were associated with pathologic complete response (pCR) and
7 higher TIL levels after chemotherapy completion in patients with *BRCA* pathogenic
8 mutations. Our data supports that (i) NAC should be reconsidered in luminal BCs with *BRCA*
9 pathogenic mutation, (ii) TILs could be a biomarker for response to immune checkpoint
10 blockade in luminal BCs with *BRCA* pathogenic variant who did not achieve a pCR and (iii)
11 exploiting the antitumor immune response in luminal BCs could be an area of active research.

12

1 **Abstract:**

2 *Introduction:* Five to 10% of breast cancers (BCs) occur in a genetic predisposition context
3 (mainly *BRCA* pathogenic variant). Nevertheless, little is known about immune tumor
4 infiltration, response to neoadjuvant chemotherapy (NAC), pathologic complete response
5 (pCR) and adverse events according to *BRCA* status.

6 *Material and methods:* Out of 1199 invasive BC patients treated with NAC between 2002 and
7 2012, we identified 267 patients tested for a germline *BRCA* pathogenic variant. We evaluated
8 pre-NAC and post-NAC immune infiltration (TILs). Response to chemotherapy was assessed
9 by pCR rates. Association of clinical and pathological factors with TILs, pCR and survival
10 was assessed by univariate and multivariate analyses.

11 *Results:* Among 1199 BC patients: 46 were *BRCA*-deficient and 221 *BRCA*-proficient or wild
12 type (WT). At NAC completion, pCR was observed in 84/266 (31%) patients and pCR rates
13 were significantly higher in *BRCA*-deficient BC ($p= 0.001$), and this association remained
14 statistically significant only in the luminal BC subtype ($p= 0.006$). The interaction test
15 between BC subtype and *BRCA* status was nearly significant ($P_{interaction}=0.056$). Pre and post-
16 NAC TILs were not significantly different between *BRCA*-deficient and *BRCA*-proficient
17 carriers; however, in the luminal BC group, post-NAC TILs were significantly higher in
18 *BRCA*-deficient BC. Survival analysis were not different between *BRCA*-carriers and non-
19 carriers.

20 *Conclusion:* *BRCA* mutation status is associated with higher pCR rates and post-NAC TILs in
21 patients with luminal BC. *BRCA*-carriers with luminal BCs may represent a subset of patients
22 deriving higher benefit from NAC. Second line therapies, including immunotherapy after
23 NAC, could be of interest in non-responders to NAC.

1 **Introduction**

2 **Neoadjuvant or pre-operative chemotherapy (NAC)** is classically administered to patients
3 with inflammatory or locally advanced breast cancer (BC). Beyond increasing breast-
4 conserving surgery rates (1), it also serves as an *in vivo* chemosensitivity test and the analysis
5 of residual tumor burden may help understanding treatment resistance mechanisms (2). In
6 addition, it helps refining the prognosis of patients after NAC, as pathological complete
7 response (pCR) after NAC is associated with a better long term survival (1,3).

8 Nearly 5% of breast cancers occur in a context of **genetic predisposition**, mostly represented
9 by monoallelic pathogenic variants of *BRCA1*, *BRCA2* or *PALB2* genes (4). Patients with
10 loss-of-function of the BRCA1 or 2 proteins have a higher cumulated breast cancer risk, with
11 a cumulated life time risk at eighty years old of 72% (*BRCA1*) and 69% (*BRCA2*)(5). The
12 peak incidence for *BRCA1* mutation carriers occurs between 41 and 50 years old (28.3 per
13 1000 person-years), whereas it occurs ten years later for *BRCA2* mutation carriers (30.6 per
14 1000 person-years between 51 and 60) (5). *BRCA1* and *BRCA2* are tumor-suppressor genes
15 that code for proteins involved in homologous recombination (HR) repair. HR deficiency
16 (HRD) occurs when the second allele is inactivated by allelic deletion (often detected by
17 LOH), genic alteration or promoter methylation (for *BRCA1* only). Biallelic *BRCA1/2*
18 inactivation results in genomic instability and theoretically increases the somatic mutational
19 load (6).

20 Tumors associated with germline or somatic *BRCA1/2* pathogenic mutations **display**
21 **different patterns when compared with sporadic BCs**. Cancers occurring among *BRCA1*
22 carriers are more frequently classified as medullary (7), whereas histological subtypes among
23 *BRCA2* carriers tend to be more heterogeneous (8). In addition, *BRCA1* carriers are more
24 frequently ER-negative, PR-negative and lack *HER2* amplification (*i.e.* display a triple

1 negative (TNBCs) phenotype (9))- whereas in *BRCA2* carriers, a similar prevalence of ER-
2 positive tumors has been described when compared with sporadic controls (10–13).

3 Most of patients with TNBCs receive **chemotherapy** (14,15). Due to the alteration of *BRCA1*
4 and *BRCA2* proteins in tumor cells, *BRCA*-mutated cells are unable to properly repair double-
5 strand breaks, classically induced by DNA-alkylating agents (16). Hence, *BRCA* deficiency
6 has sometimes been associated with a higher sensitivity to platinum agents when compared to
7 other types of neoadjuvant chemotherapy regimens (17–19). However, the effectiveness of
8 standard NAC in all BC subtypes associated with *BRCA* pathogenic variants compared to
9 controls has been poorly explored so far.

10 The role of **tumor infiltrating lymphocytes (TILs)** in BC has been extensively studied over
11 the last decade. High levels of TILs before NAC are associated with higher pCR rates and
12 better survival, especially for TNBC and *HER2*-positive BCs (20,21). However, despite a
13 growing interest in the field of immunity and oncology, characterization and quantification of
14 TILs across all BC subtypes according to *BRCA* status has not been extensively described.
15 Similarly, no study has evaluated so far, the evolution of immune infiltration after NAC
16 according to *BRCA* status.

17 The objective of the current study is to determine if pre and post-NAC TILs, chemosensitivity
18 and prognosis differ according to *BRCA* status in a cohort of BC patients treated with NAC.

19

1 **Material and methods:**

2 *Patients and Tumors*

3 The study was performed on a retrospective institutional cohort of 1199 female patients with
4 T1-T3N_xM0 invasive BC (NEOREP Cohort, CNIL declaration number 1547270) treated with
5 NAC at Institute Curie (Paris and Saint-Cloud) between 2002 and 2012. The cohort included
6 unifocal, unilateral, non-recurrent, non-metastatic tumors, excluding T4 tumors
7 (inflammatory, chest wall or skin invasion). Approved by the Breast Cancer Study Group of
8 Institute Curie, the study was conducted according to institutional and ethical rules
9 concerning research on tissue specimens and patients. Informed consent from patients was not
10 required.

11 Information on family history, clinical characteristics (age; menopausal status; body mass
12 index) and tumor characteristics (clinical tumor stage and grade; histology; clinical nodal
13 status; ER, PR and *HER2* status; BC subtype; mitotic index; Ki67) were retrieved from
14 electronic medical records. All the patients received NAC, and additional treatments were
15 decided according to national guidelines (see **Supplementary material**).

16

17 *Tumors samples*

18 In accordance with French national guidelines (22), cases were considered estrogen receptor
19 (ER)-positive or progesterone receptor (PR)-positive if at least 10% of tumor cells expressed
20 estrogen and/or progesterone receptors (ER/PR), and endocrine therapy was prescribed when
21 this threshold was exceeded. *HER2* negative status was defined as 0 or 1 + on
22 immunohistochemistry (IHC) stained tissue section. IHC 2 + scores were subsequently
23 analyzed by fluorescence *in situ* hybridization (FISH) to confirm *HER2* positivity.

1 Pathological BC were classified into subtypes (TNBC, *HER2*-positive, and luminal *HER2*-
2 negative [referred to hereafter as “luminal”]) (see **Supplementary material**).

3

4 ***TIL levels, pathological complete response and pathological review:***

5 TIL levels were evaluated retrospectively for research purposes, by two pathologists (ML and
6 DdC) specialized in breast cancer. TIL levels were assessed on formalin-fixed paraffin-
7 embedded (FFPE) tumor tissue samples from pretreatment core needle biopsies and the
8 corresponding post-NAC surgical specimens, according to the recommendations of the
9 international TILs Working Group before (23) and after NAC (24). TILs were defined as the
10 presence of a mononuclear cell infiltrate (including lymphocytes and plasma cells, excluding
11 polymorphonuclear leukocytes). TILs in direct contact with tumor cells were counted as intra-
12 tumoral TILs (IT TILs) and those in the peri-tumoral areas as stromal TILs (str TILs). They
13 were evaluated both in the stroma and within tumor scar border, after excluding areas around
14 ductal carcinoma *in situ*, tumor zones with necrosis and artifacts, and were scored
15 continuously as the average percentage of stroma area occupied by mononuclear cells.

16 We defined pathological complete response (pCR) as the absence of invasive residual tumor
17 from both the breast and axillary nodes (ypT0/is N0).

18

19 ***BRCA status***

20 Genetic counseling was offered based on individual or family criteria (see Supplemental
21 material). When constitutional genetic analysis of *BRCA1* and *BRCA2* genes were required,
22 Denaturing High Performance Liquid Chromatography (DHPLC) and Sanger sequencing
23 were performed to search for point alterations, and Quantitative Multiplex Polymerase Chain
24 Reaction of Short Fluorescent (QMPSF) to research large gene rearrangements between 2002

1 and 2012. In case of previously known pathogenic familial variants, targeted tests were
2 performed.

3

4 ***Survival endpoints***

5 Relapse-free survival (RFS) was defined as the time from surgery to death, loco-regional
6 recurrence or distant recurrence, whichever occurred first. Overall survival (OS) was defined
7 as the time from surgery to death. For patients for whom none of these events were recorded,
8 data was censored at the time of last known contact. Survival cutoff date analysis was
9 February 1st, 2019.

10

11 ***Statistical analysis***

12 Pre- and post-NAC TIL levels were analyzed as continuous variables. All analyses were
13 performed on the whole population and after stratification by BC subtype. To compare
14 continuous variables among different groups, Wilcoxon-Mann-Whitney test was used for
15 groups including less than 30 patients and for variables displaying multimodal distributions;
16 otherwise, student t-test was used. Association between categorical variables was assessed
17 with chi-square test, or with the Fisher's exact test if at least one category included less than
18 three patients. In boxplots, lower and upper bars represented the first and third quartile
19 respectively, the medium bar was the median, and whiskers extended to 1.5 times the inter-
20 quartile range. Factors predictive of pCR were introduced in a univariate logistic regression
21 model. Covariates selected for multivariate analysis were those with a *p*-value no greater than
22 0.1 after univariate analysis. Survival probabilities were estimated by Kaplan-Meyer method,
23 and survival curves were compared with log-rank tests. Hazard ratios (HR) and their 95%
24 confidence intervals (CI) were calculated with the Cox proportional hazard model. Analyses
25 were performed with R software version 3.1.2. Significance threshold was of 5%.

1 **Results**

2 ***Study population and tumors characteristics***

3 The total number of patients included in the neoadjuvant cohort was 1199. Among the whole
4 population, germline *BRCA* pathogenic variant status was available for 267 patients (22.3%),
5 and was not obtained for 932 patients (77.73%, **Supplementary Figs. S1**). Median age of
6 cohort's population was 48 years old (range 24-80) and most patients (n=747, 62%) were
7 premenopausal. Median BMI index was 24.74, and 25.8% had direct family history of breast
8 cancer. Patients repartition by subtype was as follows: luminal (n=518, 44%), TNBC (n= 376,
9 31%), *HER2*-positive (n= 295, 25%).

10 Patients with available *BRCA* status were significantly different from patients with *BRCA*
11 status unknown. They were younger, had lower body mass index, were more likely to be
12 diagnosed with grade III, TNBC of no specific type (NST), and to receive standard
13 anthracyclines-taxanes containing regimens than patients not screened (p< 0.001) (**Table1**,
14 **Supplementary Figs. S2**).

15 Among the 267 screened patients, the distribution of *BRCA* status was as follows: *BRCA*-
16 proficient n=221 (83%); *BRCA*-deficient, n= 46 (17%) (*BRCA1*-deficient, n=31 (67.39%);
17 *BRCA2*-deficient, n = 14 (30.43%) and *BRCA1+2*-deficient, n=1 (2.17%)). Median age at
18 diagnosis for patient with available *BRCA* mutation status was 40 years old (range 24-70) and
19 most patients (n=227, 85%) were premenopausal. Patients repartition by subtype was as
20 follows: luminal (n=90, 33.7%), TNBC (n= 110, 41.2%), *HER2*-positive (n= 67, 25.1%)
21 (**Supplementary Table S1, Supplementary Fig. S2**).

22 Carriers of a *BRCA* pathogenic variant were more likely to have familial history of breast
23 cancer (73.9% vs. 52.3%, p= 0.012), and to be diagnosed with TNBC (58.7% vs 37.6%; p=

1 0.006) than *BRCA*-proficient patients (**Table 1**). No other pattern among age, body mass
2 index, histology, tumor size, nor proliferation indices (grade, mitotic index, KI67) was
3 significantly different according to *BRCA* variant status. These results were substantially
4 similar after the subgroup analysis of BC subtype (**Supplementary Table S2**).

Table1. Patients' characteristics among the whole population

Characteristics	Class	All	BRCA mutation	BRCA wild-type	Not screened	p

Missing data : Menopausal status, n=10; BMI (continuous), n=6; BMI class, n=6; Family history, n=3; Clinical tumor stage, n=1; Clinical nodal status, n=1; Histology, n=19; Grade, n=42; Mitotic index, n=502; Pre-NAC str TILs, n=482; Pre-NAC IT TILs, n=482; NAC regimen, n=3; pCR status, n=3; Post-NAC Nodal involvement, n=2; Post-NAC str TILs, n=482; Post-NAC IT TILs, n=714.

Abbreviations: NAC=neoadjuvant chemotherapy ; BMI=body mass index; NST= no special type; TNBC= triple negative breast cancer ; str TILs= stromal tumor-infiltrating lymphocytes ; IT TILs= intratumoral-infiltrating lymphocytes;

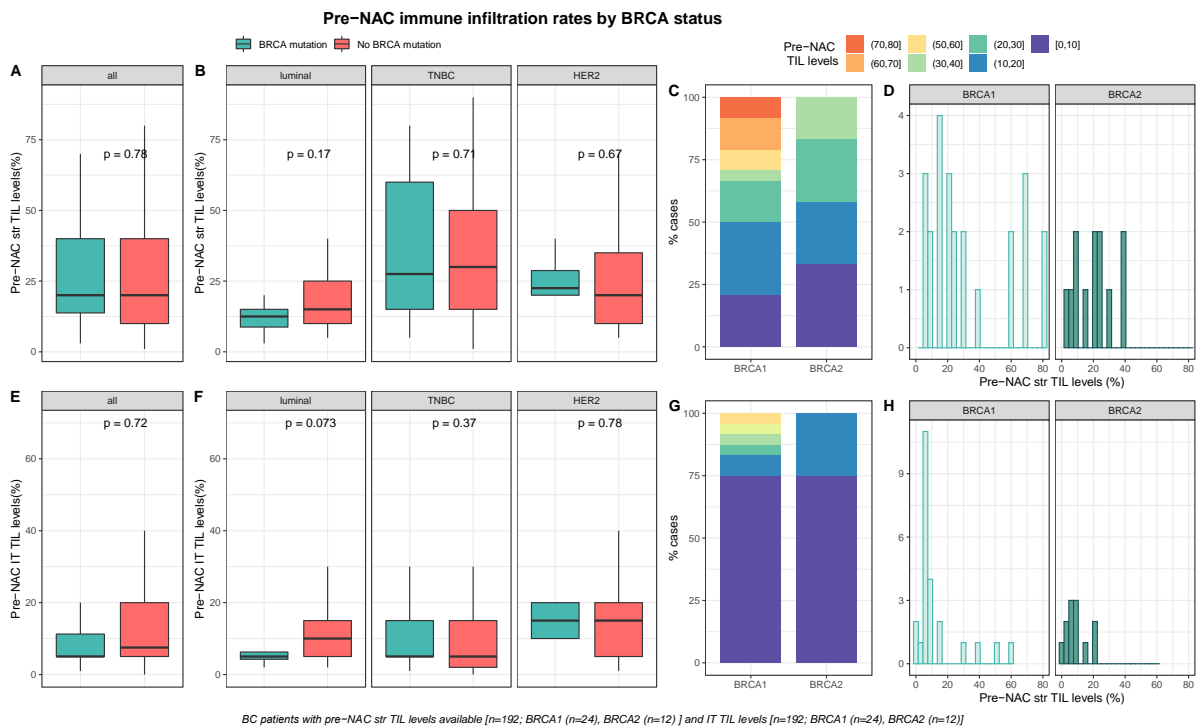

AC=anthracyclines; pCR=Pathologic complete response.

The "n" denotes the number of patients. In case of categorical variables, percentages are expressed between brackets.

In case of continuous variables, mean value is reported. In case of nonnormal continuous variables, median value is reported, with interquartile range between brackets.

- 1
- 2 Baseline TILs were available for 192 out of 267 screened patients (72%). Neither pre-NAC
- 3 str TIL levels (Figs 1A-D), nor IT TILs (Figs 1E-H) were significantly different by BRCA
- 4 status (Supplementary Table S1), nor in each BC subtype (Supplementary Table S2).

- 1 There was a strong, positive, linear relationship between stromal and intra-tumoral TILs
- 2 (Spearman correlation coefficient of 0.74, $p < 0.001$, **Supplementary Fig. S3**)

3
4 **Figure 1.** Associations between pre-NAC TILs and *BRCA* status in whole population, and by breast cancer subtype. Bottom and top bars of
5 the boxplots represent the first and third quartiles, respectively, the medium bar is the median, and whiskers extend to 1.5 times the
6 interquartile range. **A**, stromal lymphocytes among the whole population (All(n=192), *BRCA* mutation (n=36), *BRCA* wild-type(n=156)). **B**,
7 stromal lymphocytes in each BC subtype (Luminal(n=52), *BRCA* mutation(n=8), *BRCA* wild-type(n=44); TNBC(n=97), *BRCA* mutation(n=24),
8 *BRCA* wild-type(n=73); *HER2*(n=43),*BRCA* mutation(n=4), *BRCA* wild-type(n=39)). **C**, percentage of tumor according to pre-NAC stromal
9 lymphocytes levels binned by 10% increment in patients with *BRCA*-deficient (*BRCA1* (n=24), *BRCA2*(n=12)). **D**, distribution of pre-NAC
10 stromal lymphocytes by gene mutations (histogram plot) in patients with *BRCA*-deficient (*BRCA1* (n=24), *BRCA2*(n=12)). **E**, intratumoral
11 lymphocytes among the whole population (All(n=192), *BRCA* mutation (n=36), *BRCA* wild-type(n=156)). **F**, intratumoral lymphocytes in each
12 BC subtype (Luminal(n=52), *BRCA* mutation(n=8), *BRCA* wild-type(n=44); TNBC(n=97), *BRCA* mutation(n=24), *BRCA* wild-type(n=73);
13 *HER2*(n=43),*BRCA* mutation(n=4), *BRCA* wild-type(n=39)). **G**, Percentage of tumor according to pre-NAC intratumoral lymphocytes levels
14 binned by 10% increment in patients with *BRCA*-deficient (*BRCA1* (n=24), *BRCA2*(n=12)). **H**, distribution of pre-NAC intratumoral
15 lymphocytes by gene mutations (histogram plot) in patients with *BRCA*-deficient (*BRCA1* (n=24), *BRCA2*(n=12)).

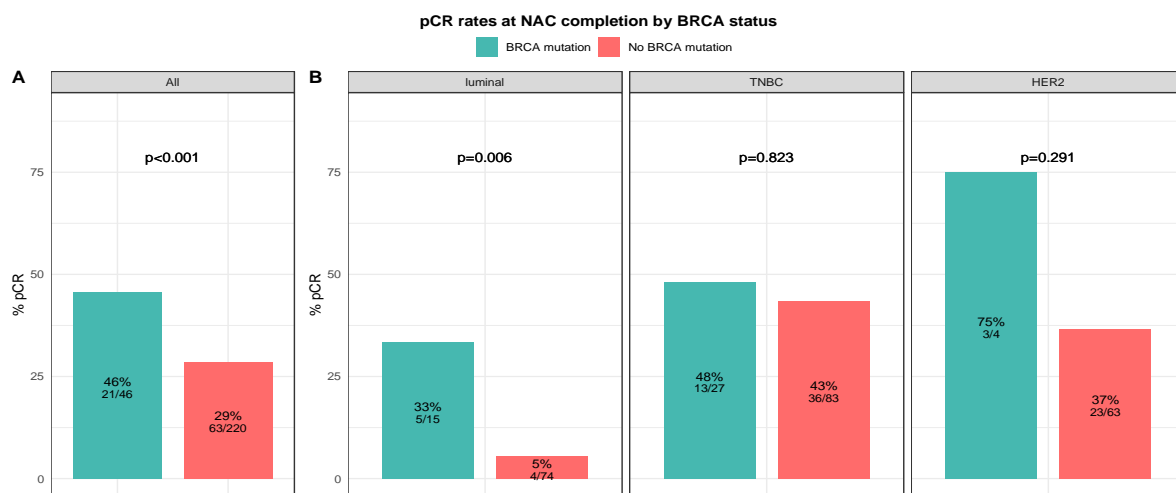

16 17 18 **Response to treatment and post-NAC immune infiltration**

19 *Response to treatment*

20 At NAC completion, pCR was observed in 84 out of 266 (31%) patients and pCR rates were
21 significantly different by BC subtype (luminal: 10% (9/89), TNBC: 45% (49/110) and *HER2*-
22 positive 39% (26/67), $p < 0.001$). Pre-NAC str TIL levels were significantly higher in tumors
23 for which pCR was achieved ($p < 0.001$) and there was a significant association between pre-
24 NAC TIL levels and pCR status in the whole population (all: OR = 1.03, CI95% [1.02 – 1.05

1], $p < 0.001$; Supplementary Fig. S3) and in the TNBC subgroup (luminal: OR = 1.03 , CI95%
 2 [1 – 1.09], $p = 0.21$; TNBC: OR = 1.03; CI95% [1–1.04], $p = 0.007$; *HER2*-positive: OR =
 3 1.02, CI95% [0.99–1.06], $p = 0.23$; **Supplementary Fig. S4**).

4 pCR rates were significantly higher in patients with *BRCA*-deficient breast cancers (45.7%
 5 (21/46) versus 28 % (63/221) in *BRCA*-proficient, $p < 0.035$, **Supplementary Table S1**,
 6 **Figure 2**). After the subgroup analysis of BC subtype, this was confirmed only in the luminal
 7 BC subtype (33.3% (5/15), $p = 0.006$), but not in TNBC and *HER2*-positive BCs (48.1%
 8 (13/27), $p = 0.823$ and 75% (3/4), $p = 0.291$, respectively, **Supplementary Table S2, Figure**
 9 **2**). The interaction test between BC subtype and *BRCA* status was nearly significant
 10 ($P_{interaction} = 0.056$).

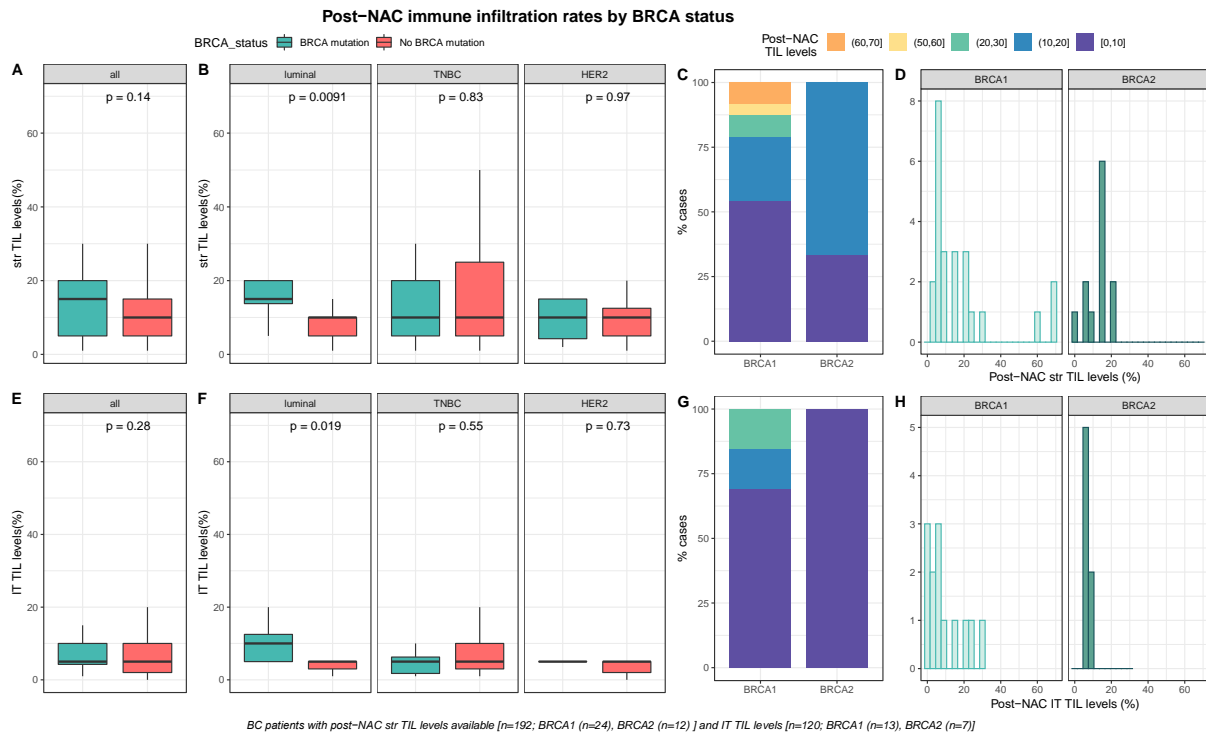

11 BC patients with pCR rates treated with NAC [(n=266); Luminal (n= 89), TNBC (n= 110), *HER2*-positive (n= 67)]

12 **Figure 2.** Barplot of associations between response to treatment and *BRCA* status in whole population, and by breast cancer subtype. **A**,
 13 among the whole population (All(n=266), *BRCA* mutation (n=46), *BRCA* wild-type(n=220)). **B**, by BC subtype (Luminal(n=89), *BRCA*
 14 mutation(n=15), *BRCA* wild-type(n=74); TNBC(n=110), *BRCA* mutation(n=27), *BRCA* wild-type(n=83); *HER2*(n=67),*BRCA* mutation(n=4),
 15 *BRCA* wild-type(n=63)).

16 However, *BRCA* status was not significantly associated with pCR after multivariate analysis,
 17 and only BC subtype (TNBC, OR = 7.14, CI95% [3.39 - 16.57], $p < 0.001$; *HER2*-positive,
 18 OR = 5.64, CI95% [2.5 - 13.78], $p < 0.001$), tumor size (T2, OR = 0.37, CI95% [0.16 - 0.83
 19], $p = 0.017$; T3, OR = 0.21, CI95% [0.08 - 0.55], $p = 0.002$) and pre-NAC str and IT TILs

1 (OR = 1.03, CI95% [1.02 - 1.05], $p= 0.001$ and OR = 1.04, CI95% [1.02 - 1.07], $p= 0.002$)
 2 were independent predictors of pCR (**Supplementary Table S3**).

 16 distribution of pre-NAC intratumoral lymphocytes by gene mutations (histogram plot) in patients with *BRCA*-deficient (*BRCA1* (n=13),
 17 *BRCA2*(n=7)).

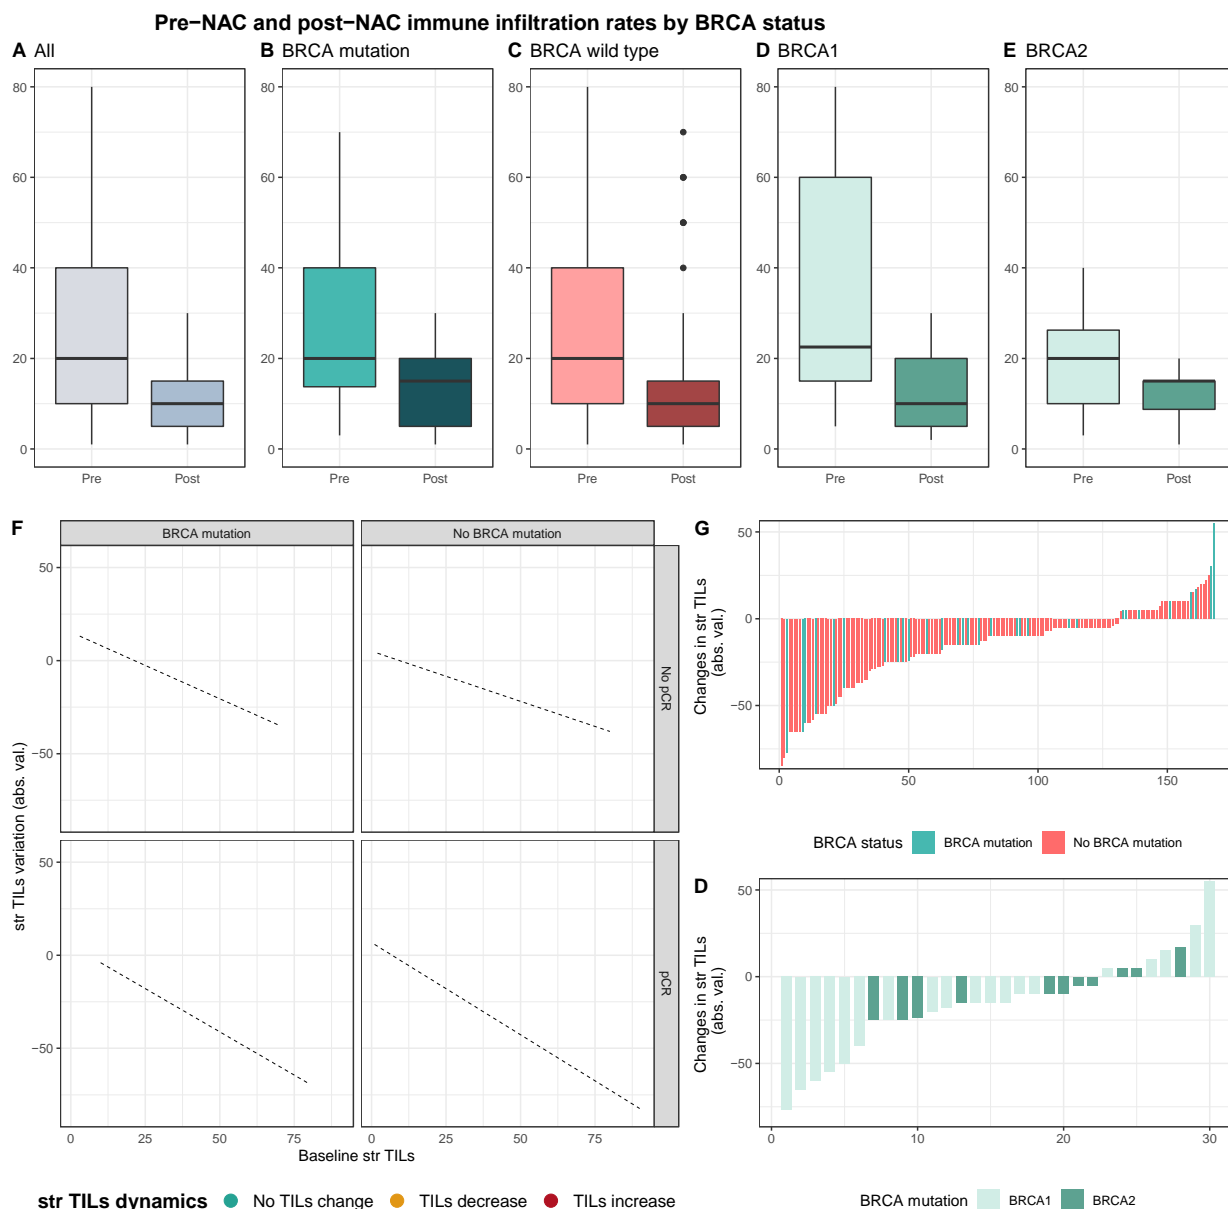

18
 19 After NAC, str and IT TILs were available in 192 (72%) and 120 (45%) patients respectively.
 20 Post-NAC immune infiltration (whether intra-tumoral or stromal) was not significantly
 21 different between *BRCA*-deficient and *BRCA*-proficient carriers (**Supplementary Table S1**,
 22 **Fig. 3A-3E**). However, both str and IT TIL levels were significantly higher in tumors with

1 *BRCA* pathogenic mutations when compared with wild-type tumors in luminal BCs (median
2 str TIL levels: 15% vs. 10%, $p= 0.009$ and median IT TIL levels : 10% vs. 5%, $p= 0.019$,
3 respectively, **Supplementary Table S2, Figure 3**).

4 Median pre-NAC str TIL were higher than after NAC (20% vs 10%, 11.95%), also according
5 to *BRCA* status and type (**Supplementary Table S1, Fig. 4**). There was no correlation
6 between pre and post NAC str TILs (correlation coefficient of 0.13 and $p < 0.06$,
7 **Supplementary Fig. S5A**) and there was a weak, positive, linear relationship between pre
8 and post NAC IT TIL levels (correlation coefficient of 0.31 and $p < 0.001$, **Supplementary**
9 **Fig. S5B**).

10 **Survival analysis**

11 After a median of follow-up of 90.4 months (range from 0.2 to 187 months), 73 patients
12 experienced relapse, and 38 died. RFS and OS were not significantly different between
13 carriers of a *BRCA* pathogenic variant and *BRCA*-proficient patients, neither were they in
14 screened population nor after the subgroup analysis of BC subtype (**Supplementary Figs. S6-**
15 **7**).

1 *BC patients with pre and post-NAC str TIL levels available [n=192; BRCA mutation (n= 36), BRCA wild type (n= 156), BRCA1 (n=24), BRCA2 (n=12)]*

2 **Figure 4.** Pre-NAC and post-NAC stromal immune infiltration rates in the whole population and by BRCA status. **A-E**, bar plots of str TIL
3 levels before and after NAC in the whole population and in *BRCA* pathogenic variant. Bottom and top bars of the boxplots represent the
4 first and third quartiles, respectively, the medium bar is the median, and whiskers extend to 1.5 times the interquartile range. (All(n=192);
5 *BRCA* mutation (n=36), *BRCA* wild-type(n=156); *BRCA1*(n=24), *BRCA2*(12)). **F**, variation of str TIL levels according to the pre-NAC str TIL
6 levels binned by BRCA status and response to chemotherapy. Points represent the difference between pre- and post-NAC paired TIL levels
7 values of a given patient and are colored according to TIL variation category (TIL level decrease: yellow/no change: green/increase: red)
8 (All(n=191), *BRCA* mutation (n=36), *BRCA* wild-type(n=155)). **G-D**, waterfall plot representing the variation of TIL levels according to *BRCA*-
9 deficient (*BRCA1*-deficient, *BRCA2*-deficient); each bar represents one sample, and samples are ranked by increasing order of TIL level
10 change. Paired samples for which no change was observed have been removed from the graph. (All(n=191), *BRCA* mutation [(n=36),
11 *BRCA1*, n= 24; *BRCA2*= 12)], *BRCA* wild-type(n=155)).

1 Discussion

2 In the current study, we did not identify any association between *BRCA* status and immune
3 infiltration whatever the type of TILs (IT, str). We found a better response to neoadjuvant
4 chemotherapy in tumors associated with a germline *BRCA* pathogenic variant when compared
5 to *BRCA*-WT, but the latter was limited to the group of luminal BCs and was not statistically
6 significant after multivariate analysis. Probably in relation, we recovered higher post-NAC
7 lymphocyte infiltration in *BRCA*-deficient tumors in the luminal BC subgroup.

8 Regarding pre-treatment immune infiltration, S nderstrup and colleagues (25) analyzed str
9 TIL levels in a nationwide cohort of *BRCA1* and *BRCA2* carriers with primary BCs. They
10 found a greater prevalence of high stromal TILs (defined as TILs-positive tumors with $\geq 60\%$
11 str TILs) in *BRCA1*-deficient tumors (n=243) when compared with *BRCA2*-deficient tumors
12 (n=168) (36% versus 15 % respectively, $p < 0.0001$). However, no control group with *BRCA*-
13 WT tumors was available in this study. In a small study of 85 TNBC patients, Solinas and
14 colleagues (26) investigated the distribution of TILs subpopulations. The tumors of patients in
15 the *BRCA1* or *BRCA2*-mutated group displayed a higher prevalence of TILs-positive tumors
16 (defined as tumors with $\geq 10\%$ str or IT TILs) when compared with the *BRCA*-WT (93.2%
17 versus 75.6% respectively, $p=0.037$). No other statistically significant differences were
18 identified between *BRCA*-carriers and non-carriers, neither in TILs subpopulations nor their
19 location. More recently, Telli and colleagues (27) investigated the association between TILs,
20 homologous recombination deficiency (HDR) and *BRCA1/2* status in a cohort of 161 TNBC
21 patients pooled from 5 phase II neoadjuvant clinical trials of platinum-based therapy. They
22 found that IT TILs and str TILs density were not associated with *BRCA1/2* status ($p=0.312$
23 and $p= 0.391$, respectively). Consistently with Telli *et al*, we did not observe any difference
24 in baseline immune infiltration according to *BRCA* status.

1 Some retrospective studies suggested that tumors displayed higher chemosensitivity
2 according to *BRCA*-mutation status (17–19, 28–35). Arun *et al.* (31) compared pCR rates after
3 NAC between *BRCA1* or *BRCA2*-carriers (n=57 and n=23, respectively) and WT controls
4 (n=237). The majority of patients (82%) received an anthracycline-taxane containing regimen
5 as NAC. The authors found that *BRCA1* mutation was an independent positive predictor of
6 pCR (OR=3.16, 95%CI 1.55-6.42, $p= 0.002$). In the largest study so far, Wunderle *et al.*(18)
7 investigated efficacy of chemotherapy among a cohort of 355 patients composed with 16.6%
8 (59/355) of *BRCA*-carriers. Across all BC subtypes, 64.4% of patients with a *BRCA1/2*
9 pathogenic variant received anthracycline-based treatments, while the rest received
10 carboplatin. pCR was observed in 54.3% (32/59) of all *BRCA1/2* mutation carriers, and in
11 39.5% (15/34) of the *BRCA*-carriers *versus* 13% of the WT BCs in the anthracycline-regimen.
12 In our cohort, we found similar results after univariate analysis, and we additionally
13 evidenced a nearly significant interaction with BC subtype. The fact that our results were no
14 longer significant after multivariate analysis is possibly due to a lack of statistical power.

15 Furthermore, we found that both str and IT TIL levels were higher after NAC completion in
16 the luminal BCs. Whether this difference in post treatment TILs is a cause, a consequence, or
17 unrelated to response to chemotherapy remains unknown. Indeed, post-NAC TIL levels have
18 been shown to be strongly related to response to chemotherapy in BC cohorts including all
19 BC subtypes (36–38) but only a few studies have investigated the dynamic of TIL levels in
20 response to NAC. Hamy *et al.*(38) noticed that mean TIL levels decreased after chemotherapy
21 completion across all the BC subtype (pre-NAC TILs: 24.1% vs. post-NAC TILs: 13.0%, $p<$
22 0.001). This decrease was strongly associated with high pCR rates, and the variation of TIL
23 levels was strongly inversely correlated with pre-NAC TIL levels (and the variation of TIL
24 levels was strongly inversely correlated with pre-NAC TIL levels ($r= - 0.80$, $p< 0.001$).

1 Finally, in line with several recently published clinical studies (39–41), we found that survival
2 outcomes were not different between *BRCA*-carriers and non-carriers. A multivariate study,
3 including 223 BC patients carrying *BRCA* pathogenic variants and 446 controls with sporadic
4 BC matched for age and year of diagnosis, showed no difference in terms of specific BC
5 survival between *BRCA1* or *BRCA2* mutation carriers and controls (42). Templeton et al.
6 evaluated a total of 16 studies comprising data from 10,180 patients and concluded that *BRCA*
7 pathogenic mutations were not associated with a worse overall survival (43).

8 Limits of our study include its retrospective design as well as small effectives potentially
9 leading to a lack of statistical power. Moreover the incidence of bi-allelic pathogenic
10 alterations in HR-related genes according to somatic origin is well-known and ranges from 1
11 to 2 % (44) but we did not explore somatic mutational status in the tumor tissues in the
12 current study.

13 It also has several strengths, for instance by being the largest cohort with a *BRCA*-WT control
14 group, and analyses performed after stratification by BC subtype. Finally, to our knowledge,
15 we provide data on post-NAC immune infiltration according to *BRCA* status for the first time.

16 Our study has several implications. First, it generates an unprecedented hypothesis that
17 luminal BC patients with germline *BRCA* pathogenic variants may represent a subset of
18 luminal BCs that are more likely to benefit from chemotherapy as primary treatment than the
19 whole luminal BC population. It is known that the absolute benefit of chemotherapy is lower
20 in luminal BC than in the other BC subtypes (45). If further validated in independent cohorts,
21 our findings might lead to reconsider standard use of chemotherapy in patients with luminal
22 BC associated with *BRCA* pathogenic mutations. Second, patients not achieving pCR may be
23 candidates for post-operative clinical trials exploring alternative therapeutic strategies. As
24 post-NAC immune infiltration seems to be higher in post-NAC specimens of luminal tumors

1 with *BRCA* pathogenic mutations, we can hypothesize that those tumors would be more likely
2 to respond to checkpoint inhibitors after chemotherapy. Second line trials using immune
3 checkpoint inhibitors (such as anti-PD-1 and anti-PD-L1 antibodies) alone or in combination,
4 together with endocrine therapy could be a relevant strategy for patients failing to reach pCR
5 at NAC completion.

Table 2. Literature Review. Abbreviations, CMF=cisplatin- methotrexate- fluorouracile ; AT=docetaxel-doxorubicine ; AC=doxorubicine-cyclophosphamide ; FAC=fluorouracile-doxorubicin-cyclophosphamide ; CEF=cyclophosphamide-epirubicine-fluorouracile ; A=anthracycline ; Dx=doxorubicine ; Do=docetaxel ; Cb=carboplatin ; Cis=cisplatin ; BEV=bevacizumab ; PTX=paclitaxel ; T=taxane.

Study	Setting /Design	Control group	Number of patient (n)	TNBC (n)	HER2-positive (n)	Luminal (n)	BRCA1	BRCA2	BRCA 1 and 2	Chemotherapy regimen *	sTILS evaluation	pCR BRCA-carriers vs non-carriers	in survival analyses	Comments
Chappuis (2002) Journal of Medical Genetics	Neoadjuvant Retrospective multicentric clinical trial	Yes	38	NA	NA	NA	7	4	0	FAC AC CEF AC+ AC + Do	No	44% vs 4%	No	pCR was achieved in 44% (4/11) of the BRCA-carriers and 4%(1/27) of the non-carriers (p=0.009). No survival analysis were experienced in this study.
Byrski (2009) JCO	Neoadjuvant Epidemiologic retrospective cohort (nationwide)	No	102	NA	6	NA	102	0	0	CMF ; AT ; AC FAC or Cis	No	23.5%	No	pCR was achieved in 23.5% of 102 patients with a BRCA1 mutation who received NAC. Especially, a complete pCR was observed in 8% (2/25) with AT- regimen (standard of care) compared to 83% (10/12) with cisplatin.
Arun (2011) JCO	Neoadjuvant Epidemiologic retrospective cohort	Yes	317	77	60	NA	57	23	0	A-single agent; AT or T-single-agent	No	46% vs 22%	Yes	pCR was achieved in 46% of BRCA1-carriers and 13% of BRCA2-carriers and 22% of BRCA non-carriers (<0.001). In the multivariate logistic model, BRCA1 status (OR=1.96, p=.03) remained as independant significant predictors of a pCR. No significant difference in overall prognosis.
Wang (2014) Annals of Oncology	Neoadjuvant Epidemiologic retrospective cohort	Yes	652	652	0	0	52	NA	0	A-single agent; AT or T-single-agent	No	53.8% vs 29.7%	Yes	The pCR rate was 31.6% in the 652 patients who received NAC. BRCA1 carriers had a significantly higher pCR rate than non-carriers (BRCA1 carriers versus non-carriers, 53.8% versus 29.7%, P < 0.001). Among women treated with anthracycline with or without taxane regimens, the pCR rate was 57.1% for BRCA1 carriers, 29.0% for non-carriers (P < 0.001). The RFS was similar between BRCA1 carriers and non-carriers.
Byrski (2014) BCRT	Neoadjuvant Epidemiologic prospective cohort	No	10	10	0	0	10	0	0	Cis	No	90%	No	90% (9/10) in BRCA1-mutated BC patients achieved a pCR after NAC with cisplatin chemotherapy.
Byrski (2015) HCCP	Neoadjuvant Epidemiologic prospective cohort	No	107	82	2	NA	107	0	0	Cis	No	61%	No	61% (65/107) in BRCA1-mutated BC patients achieved pCR after NAC with cisplatin chemotherapy. In this study of BRCA1-mutation carriers, a pCR was also achieved in 56% of 16 patients with ER-positive BC. No survival analysis were experienced in the current study.
Paluch-Shimon (2016) BCRT	Neoadjuvant Epidemiologic retrospective cohort	Yes	80	80	0	0	34	0	0	AT	No	68% vs 37%	Yes	The BRCA1-carriers had pCR rate of 68% compared with 37% among non-carriers, p = 0.01. Yet this did not translate into superior survival for BRCA1 carriers compared with non-carriers.
Bignon (2017) Breast	Neoadjuvant Epidemiologic retrospective cohort	No	53	53	0	0	46	6	1	A-single agent or AT	No	66%	Yes	The pCR rate was 38.3% [95% CI, 26%-55%] among BRCA1 mutation carriers, and 66% among the 6 BRCA2 mutation carriers, 15 relapses and 6 second cancers were recorded during the follow-up period. 11 deaths occurred, all of which were in the non-pCR group. DFS (P < .01) and OS (P < .01) were significantly better in the pCR group than the non-pCR group.
Hahnhen (2017) JAMA oncology	Neoadjuvant secondary analysis of the GeparSixto randomized clinical Trial	Yes	291	291	0	0	50		0	AT + BEV +/- Cis	No	66.7% vs 36.4%	Yes	Patients with BRCA-mutation did not derive a pCR benefit from the addition of carboplatine (65.4% vs 66.7%) compared to non-BRCA carriers (55% vs 36.4%). No significant difference in overall prognosis observed in the BRCA-mutated subgroup.
Sharma (2017) CCR	Neoadjuvant prospective, multicenter, non-randomized trial	Yes	190	190	0	0	30		0	Cb + Do	No	59% vs 56%	No	No significant difference in pCR between BRCA-carriers and WT TNBC (59% and 56%, respectively (p=0.83)). The Carboplatin-Docetaxel regimen was well tolerated and yielded high pCR rates in both BRCA associated and WT TNBC. These results are comparable to pCR of previous studies (who investigated pCR after NAC with addition of carboplatin to anthracycline-taxane chemotherapy in TNBC cohort).
Wunderle (2018) BCRT	Neoadjuvant Epidemiologic retrospective cohort	Yes	355	138	58	159	43	16	0	AT ; Cb	No	54.3% vs 12.6%	Yes	pCR was observed in 54.3% of BRCA1/2 mutation carriers, but only in 12.6% of non-carriers. The adjusted odds ratio was 2.48 (95% CI 1.26-4.91) for BRCA1/2 carriers versus non-carriers. No difference in overall survival was observed.
Saether (2018) HCCP	Neoadjuvant Epidemiologic retrospective cohort	No	12	NA	NA	NA	12	0	0	Cis + Dx or Cb + Do	No	83%	No	11 patients received a combination of cisplatin and doxorubicin, and 1 patient received carboplatin and docetaxel. 83% (10/12) of the BRCA1-carriers achieved pCR. This results were comparable to existing results found in similar studies. No information about BC subtype among the study population and the toxicity of the chemotherapy was not evaluated.
Sella (2018) Breast	Neoadjuvant Epidemiologic retrospective cohort	Yes	43	43	0	0	14	0	0	AT +/- Cb	No	67% vs 38%	No	pCR was achieved in 38% in BRCA WT compared to 67% in BRCA-associated TNBC (p = 0.232). No benefit from the addition of carboplatine in BRCA-carriers (64.3% v 67%) compared to non-BRCA carriers (44.8% v 38%) when compared to historic institutional rates with AT.
Telli (2019) CCR	5 pooled analyses of phase II	Yes	161	161	0	0	34		0	Cb + gemcitabine + Irinaparib ; Cis ; Cis + BEV ; Cb + Eribulin ; Cb + nab-PTX +/- Vorinostat	Yes	No	No	pCR was achieved in 51 (31.7%) patients. In patients with TNBC treated with neoadjuvant platinum-based therapy, iTIL and sTIL densities were not significantly associated with BRCA1/2-mutated tumor status (p=0.312 and p= 0.391). In multivariate analyses, sTIL density (OR 1.23, 95% CI 0.94-1.61, p=0.139) was not associated with pCR, but was associated with RCB OI status (OR 1.62, 95% CI 1.20-2.28, p=0.001).
Solinas (2019) Cancer Letters	Epidemiologic retrospective cohort	Yes	85	85	0	0	38	6	0	NA	Yes	No	Yes	The BRCA-mutated tumors had a significantly higher incidence of TIL-positive levels compared to WT (44% and 41%, respectively p = 0.037). No significant difference between BRCA-mutated and WT groups neither in TIL subpopulation nor their location. No difference in i-DFS and OS after stratification on TIL infiltration levels.
Senderstrup (2019) Acta Oncologica	Epidemiologic multicentric prospective cohort (nationwide)	No	411	NA	24	NA	243	168	0	NA	Yes	No	Yes	High sTILs (defined as TILs>50%) were observed in 36% in BRCA1+ and 15% in BRCA2-mutated tumors (p<0.0001). Significant association with survival (OS and DFS) was observed in BRCA1 subgroup. sTILs are an important prognostic factor in BRCA BC and increasing sTILs is associated with a better prognosis.
Our study (2020)	Epidemiologic prospective cohort	Yes	267	110	67	90	31	14	1	A-single agent; AT or T-single-agent	Yes	45.7% vs 28.6%	Yes	Among the whole population, 84 tumors achieved a pCR (31.5%). After stratification by BC subtype, pCR rates were significantly higher in luminal BRCA-mutated BCs when compared with WT tumors (33.3% vs 5.4%, p=0.006). Pre and post-NAC str or IT TILs were not significantly different between BRCA-carriers and non-carriers in whole population. In the luminal BC, both str and IT post-NAC TIL levels were significantly higher in BRCA-mutated tumors when compared with WT tumors but was no longer significant after multivariate analysis. No difference in RFS or OS between BRCA-mutated and BRCA-WT patients.

Supplementary material

1. Patients and treatments

1.1. Patients

In total, patients with T1-3NxM0 invasive breast cancer (BC) (NEOREP Cohort, CNIL declaration number 1547270) treated at Institut Curie (Paris and Saint Cloud) between 2002 and 2012 were included in this study. We included unilateral, non-recurrent, non-inflammatory, non-metastatic tumors, excluding T4 tumors. NAC regimens changed over time (anthracycline-based regimen or sequential anthracycline-taxane regimen) with trastuzumab used in an adjuvant and/or neoadjuvant setting since 2005 for *HER2*-positive tumors. All patients underwent radiotherapy. Endocrine therapy (tamoxifen or aromatase inhibitor) was prescribed when indicated. This study was approved by the Breast Cancer Study Group of Institut Curie.

1.2. Treatments

NAC regimens changed over time (anthracycline-based regimen or sequential anthracycline-taxane regimen), with trastuzumab used in an adjuvant and/or neoadjuvant setting for *HER2*-positive tumors since the middle of the past decade. Trastuzumab treatments change over time due to a change of marketing authorization during the study period. Adjuvant hormone therapy (tamoxifen, aromatase inhibitor, or GnRH agonist) was prescribed when indicated. Surgery (breast-conserving or mastectomy) was performed 4-6 weeks after NAC. Every patient received adjuvant radiotherapy. Adjuvant chemotherapy (ADJ) was decided after multidisciplinary consultation meeting considering patient characteristic, prognosis factor and response to NAC (residual disease and/or node involvement). Patient follow-up after treatment was of every 4 months during the first 2 years, then every 6 months for 3 years, and

once a year starting from the 5th year. Follow-up consisted of clinical examination associated to mammography and mammary ultrasound once a year, with annual Magnetic resonance imaging (RMI) in *BRCA*-carriers.

2. Tumor samples and pathological review

2.1. ER, PR, *HER2* status and BC subtype

Cases were considered to be estrogen receptor (ER)-positive or progesterone receptor (PR)-positive if at least 10% of the tumor cells expressed estrogen and/or progesterone receptors (ER/PR). *HER2* expression was determined by immunohistochemistry, with scoring according to the American Society of Clinical Oncology (ASCO)/College of American Pathologists (CAP) guidelines (1). Scores of 3+ were reported as positive, and scores of 1+/0 as negative. Tumors with scores of 2+ were further tested by fluorescence *in situ* hybridization (FISH). For *HER2* gene amplification, we evaluated a mean of 40 tumor cells per sample and calculated the mean *HER2* signal per nucleus. A *HER2*/CEN17 ratio ≥ 2 was considered positive, and a ratio < 2 was considered negative (1).

2.2. Other pathological parameters

Histological grade was determined as described by Elston Ellis. Mitotic cells were counted on 10 high-power fields (HPF) (x40 objective; field diameter = 0.62 mm) and cutoffs of <11, 12–22 and >22 mitoses were used to define low, intermediate and high mitotic indices, respectively, according to the international recommendations(2). Due to significant differences in distribution before and after NAC, invasive tumor cellularity was binned according to the median value (pre-NAC: 60%; post-NAC: 30%).

2.3 *BRCA* status

Since 2002, patient referral for genetic counseling depends on individual or family criteria. These criteria are based on the probability of identifying a genetic predisposition in the family of at least 10% (in particular a germline *BRCA1* or *BRCA 2* pathogenic variant). The individual criteria are: early age at diagnosis (under 40) or bilateral breast cancer: synchronous or metachronous (with the first breast cancer before age 50), or specific phenotype (triple negative cancer before age 51). The family criteria are: 3 cases of breast cancer in the same branch of heredity, or 2 cases of breast cancer including 1 under 45-50, of breast or ovarian cancer, or 2 cases of breast cancer including 1 male. The 2 cases are women relatives of the first degree (or second degree if paternal transmission).

2.4 TILs levels

Infiltrates were scored on a continuous scale, as the mean percentage of the stromal area occupied by mononuclear cells. After NAC, we assessed TIL levels within the borders of the residual tumor bed, as defined by the RCB index(3). Nothing is known about the clinical, biological and prognostic significance of TILs in the area of regression in cases of pathological response, but the TILs international working group recently called for their evaluation for research purposes. In cases of pCR, the scar area was measured on macroscopic examination. The scar appeared as a white area in the breast parenchyma corresponding to the tumor bed modified by NAC. It was characterized by the presence of histiocytes, lymphocytes, macrophages, fibrosis and elastosis. The whole fibro-inflammatory scar was evaluated on HE sections (size in mm and stromal TIL level evaluation).

Missing data: Menopausal status, n=1; BMI (continuous), n=1; BMI class, n=1; Family history, n=3; Grade, n=5; Mitotic index, n=77; Pre-NAC str TILs, n=75; Pre-NAC IT TILs, n=75; NAC regimen, n=1; pCR status, n=1; Post-NAC Nodal involvement, n=1; Post-NAC str TILs, n=75; Post-NAC IT TILs, n=147.

NAC=neoadjuvant chemotherapy; BMI=body mass index; NST=no special type; TNBC=triple negative breast cancer; str TILs=stromal tumor-infiltrating lymphocytes; IT TILs=intratymoral-infiltrating lymphocytes; AC=anthracyclines; pCR=Pathologic complete response.

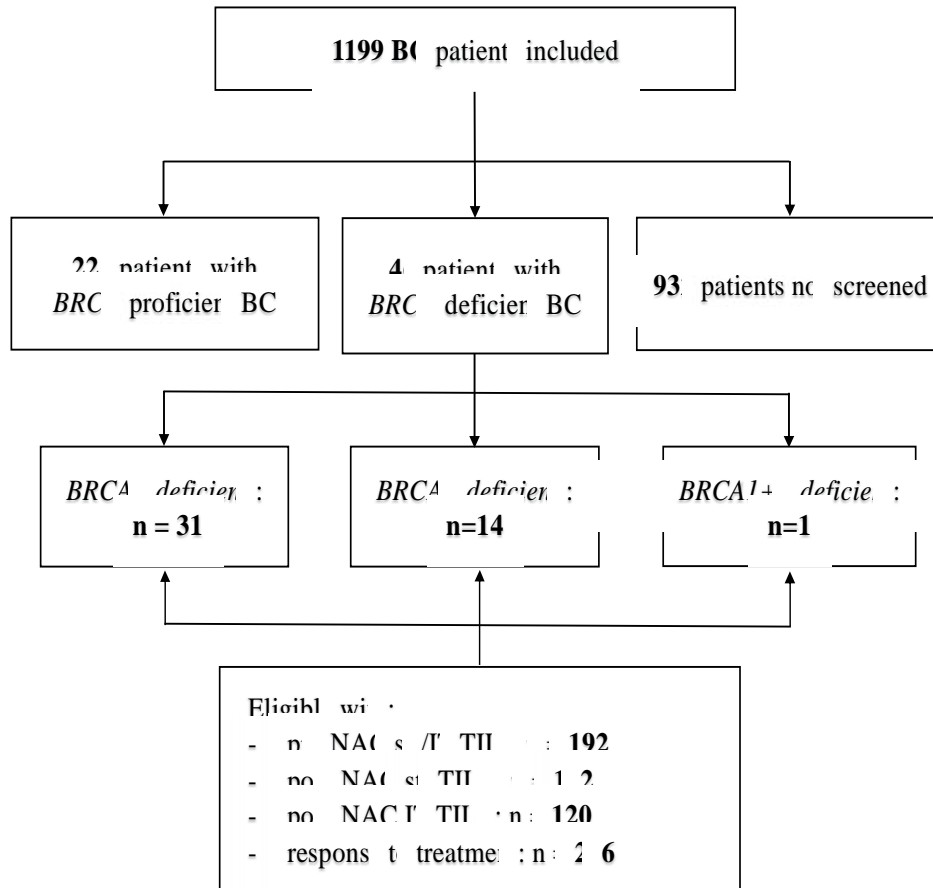

The "n" denotes the number of patients. In case of categorical variables, percentages are expressed between brackets. In case of continuous variables, mean value is reported. In case of nonnormal continuous variables, median value is reported, with interquartile range between brackets.

Supplementary Table S3. Association of BRCA status with pCR after univariate and multivariate analysis in the whole population

Supplementary Figures

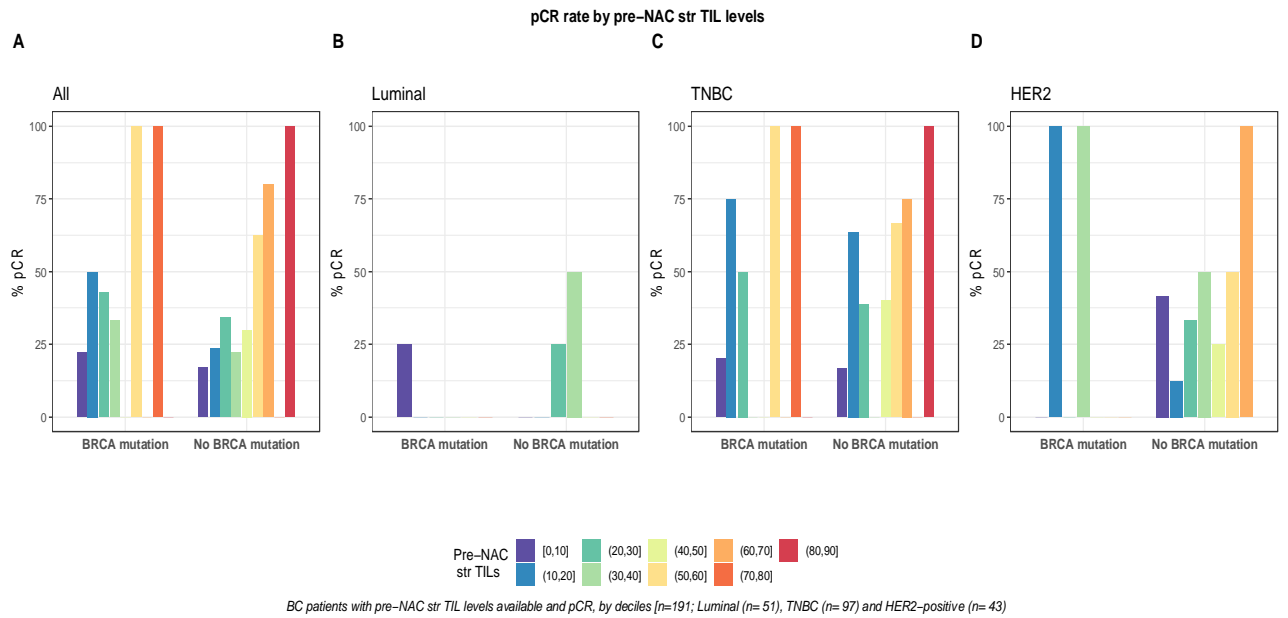

Supplementary Figure S 1. Study flow diagram of included patients and tumors samples available

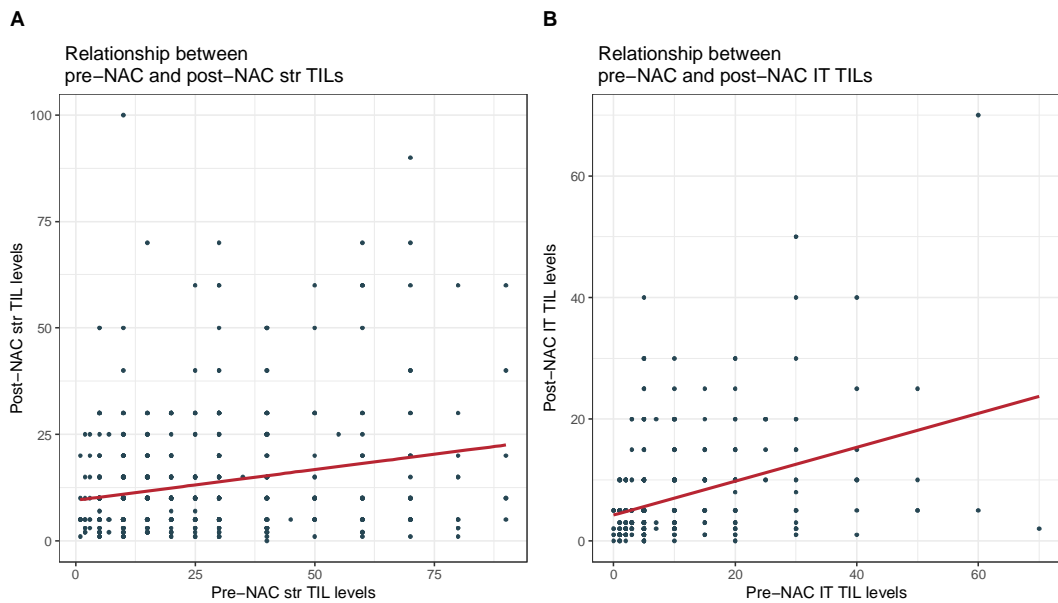

Supplementary Figure S 2. Patients' and tumors' characteristics by BRCA status. (All (n=1199), BRCA mutation (n=36), BRCA wild-type (n=156), not screened (n=1007)). **A**, Age (kernel density plot). **B**, BMI (kernel density plot). **C**, Menopausal status (barplot). **D**, Family history (barplot). **E**, Clinical tumor stage (barplot). **F**, Clinical nodal status (barplot). **G**, Histology (barplot). **H**, Grade (barplot). **I**, BC subtype (barplot).

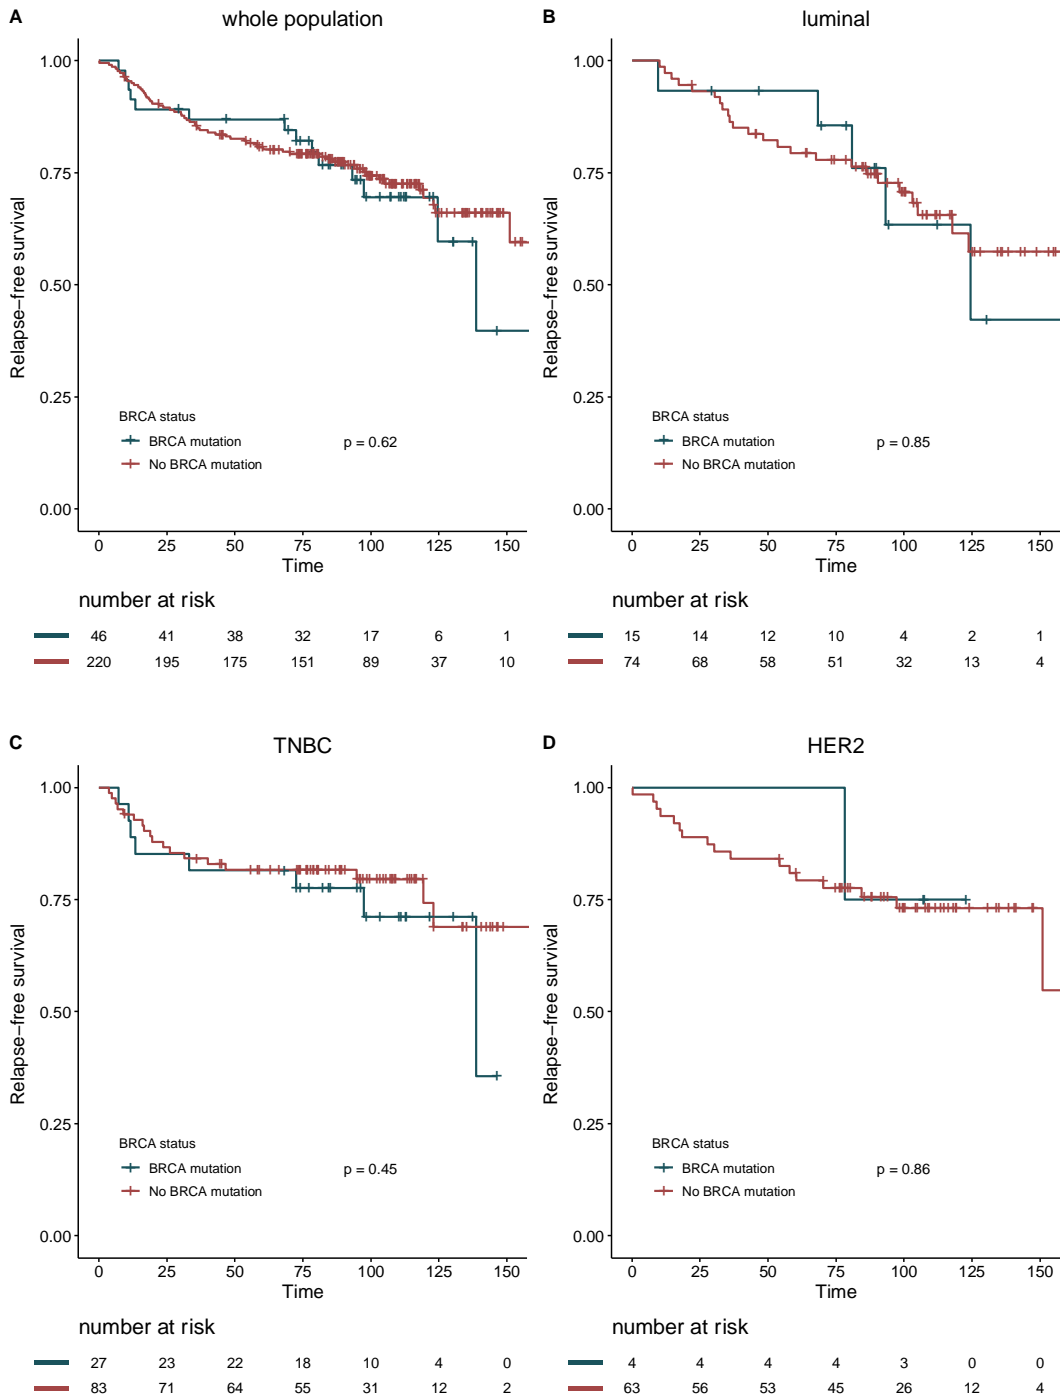

Supplementary Figure S 3. Variation of pre-NAC str TIL levels according to the pre-NAC IT TIL levels (scatterplot) (str TILs (n=192), IT TILs (n=192)).

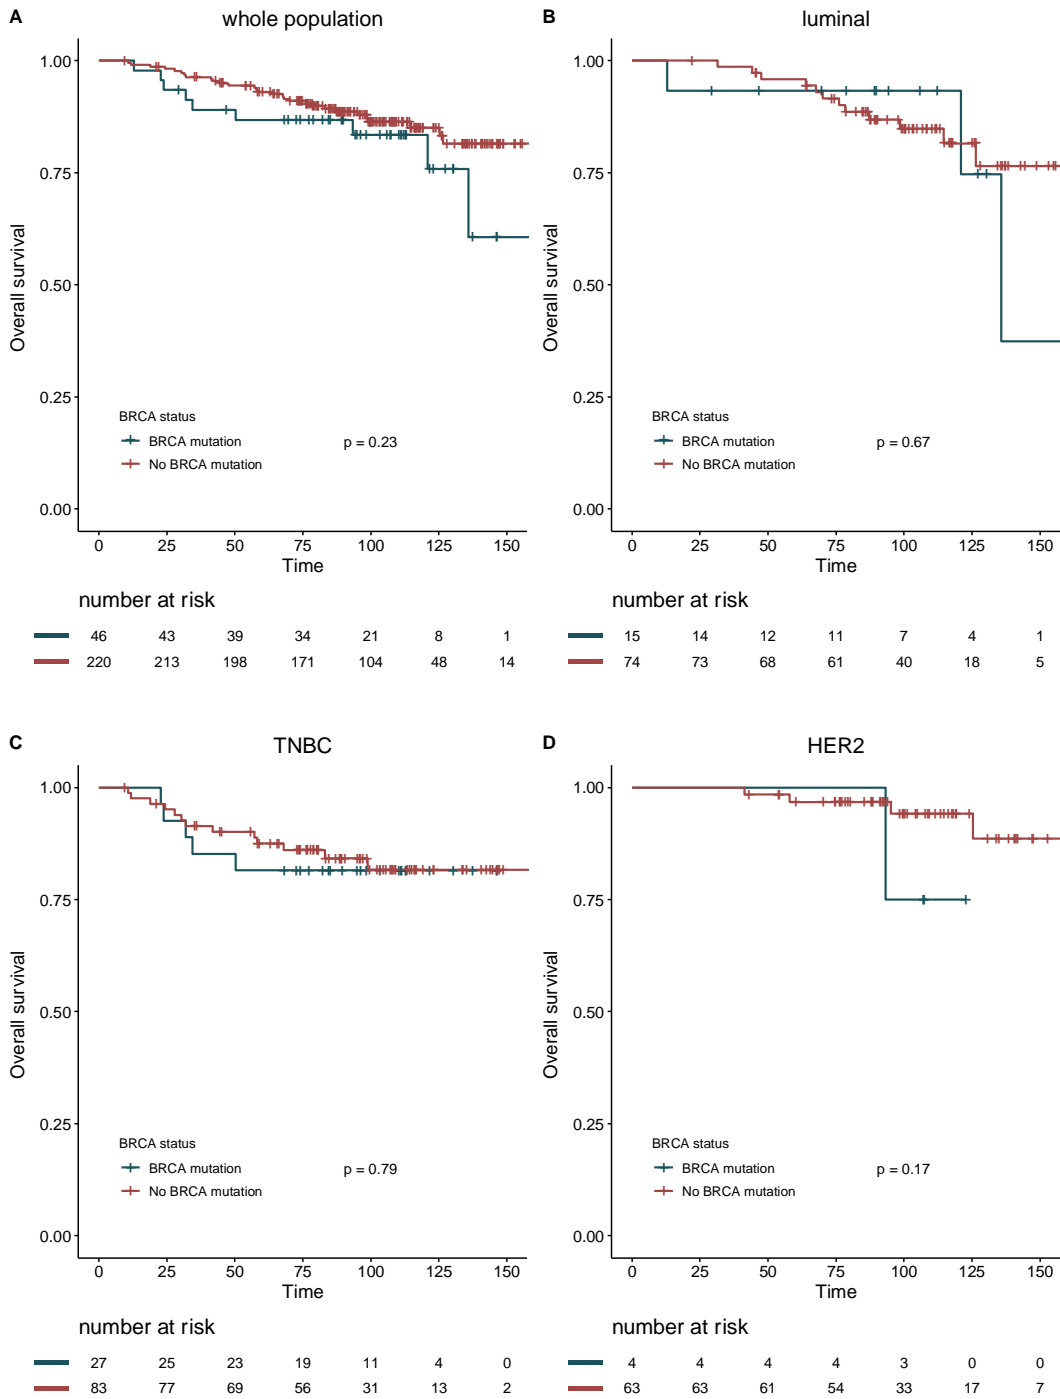

Supplementary Figure S 4. pCR rate by pre-NAC str TIL levels by BRCA status (TILs were binned by increments of 10%). **A**, whole population (n=191, BRCA mutation (n=36), BRCA wild-type(n=155)). **B**, luminal tumors (n=51, BRCA mutation(n=8), BRCA wild-type(n=43)). **C**, TNBC (n=97), BRCA mutation(n=24), BRCA wild-type(n=73)). **D**, HER2-positive BC (n=43, BRCA mutation(n=4), BRCA wild-type(n=39)).

Supplementary Figure S 5. TILs correlation between pre and post-NAC. **A**, Variation of post-NAC str TIL levels according to the pre-NAC str TIL levels (scatterplot) (pre-NAC str TILs (n=192), post-NAC str TILs (n=192)). **B**, Variation of post-NAC IT TIL levels according to the pre-NAC IT TIL levels (scatterplot) (pre-NAC IT TILs (n=192), post-NAC IT TILs (n=120)).

Supplementary Figure S 6. Relapse free survival curves according BRCA status. **A**, whole population (n=267, BRCA mutation (n=46), BRCA wild-type(n=220)). **B**, luminal tumors (n=89, BRCA mutation(n=15), BRCA wild-type(n=74)). **C**, TNBC (n=110, BRCA mutation(n=27), BRCA wild-type(n=83)). **D**, HER2-positive BC (n=67, BRCA mutation(n=4), BRCA wild-type(n=63)).

Supplementary Figure S 7 . Overall survival curves according BRCA status. **A**, whole population (n=267, BRCA mutation (n=46), BRCA wild-type(n=220)). **B**, luminal tumors (n=89, BRCA mutation(n=15), BRCA wild-type(n=74)). **C**, TNBC (n=110, BRCA mutation(n=27), BRCA wild-type(n=83)). **D**, HER2-positive BC (n=67, BRCA mutation(n=4), BRCA wild-type(n=63)).
