24 immunity, HIV-1, ART, Human herpes virus,

25
26 **Summary.** HIV-Exposed Uninfected (HEU) infants are a rapidly expanding population in

27 **NOTE:** This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice.
sub-Saharan Africa and are highly susceptible to disease caused by encapsulated bacteria in

28 the first year of life. The mechanism of this increased risk is still poorly understood. We
29 therefore investigated if HIV exposure dysregulates HEU infant immunity and if this is
30 amplified by human herpes virus infection (HHV). Here, we compared monocyte enzymatic
31 function, innate and adaptive immune cell phenotype, and vaccine-induced antibody
32 responses between HEU and HUU infants. We demonstrate altered monocyte phagosomal
33 function and B cell subset homeostasis, and lower vaccine-induced anti-*Haemophilus*
34 *influenzae type b (Hib)* and anti-Tetanus Toxoid (TT) IgG titers in HEU compared to HUU
35 infants. There was no difference in the prevalence of HHV infection between HEU and HUU
36 infants. Our findings suggest that even in the era of antiretroviral therapy (ART)-mediated
37 viral suppression, HIV exposure dysregulates monocyte and B cell function during a
38 vulnerable period of immune maturation in infancy. This may contribute to the high rates of
39 invasive bacterial disease and pneumonia in HEU infants.

40 **Introduction**

41 HIV-exposed uninfected (HEU) infants are more susceptible to infection-related morbidity
42 and mortality^{1,2}. HEU infants are particularly vulnerable to invasive bacterial disease³⁻⁷
43 particularly, pneumonia⁸⁻¹³ and diarrhea^{14,15}, they have more frequent hospitalisations, more
44 severe infections and increased risk of treatment failure. However, the mechanism of this
45 increased vulnerability remains unknown. The global population of children who are HEU is
46 substantial, estimated at 1.2 million births annually, mainly within developing countries¹⁶. A
47 coordinated strategy is therefore necessary to ensure their optimal health and wellbeing¹⁷.

48

49 The vulnerability of HEU infants is a likely complex intersection of HIV-exposure immune
50 profile ‘remodelling’, an ‘inflammatory’ maternal cytokine milieu¹⁸, time of antiretroviral
51 therapy (ART) initiation¹⁹, ART use²⁰ and prophylactics²¹, increased exposure to maternal
52 viral and bacterial pathogens, and host microbial and environmental factors. Together these
53 result in a more permissive state for the development of infections¹. Many observational
54 studies have reported immunological abnormalities in HEU infants²² including highly
55 differentiated T-cells²³⁻²⁹ and B-cell subsets³⁰, altered responses to vaccines³¹⁻³³, functional
56 impairment of natural killer cells³⁴ and monocytes³⁵⁻³⁷. Furthermore, few studies have
57 considered early transmission of immunomodulatory human herpes virus’ (HHVs),
58 cytomegalovirus (CMV)³⁸ and Epstein Barr virus (EBV)³⁹ recrudescence during pregnancy
59 on HEU immunity. HHVs are important as they are implicated in delayed growth^{40,41}, poor
60 neurodevelopment, altered mitochondria DNA⁴² and inflammation in HEU infants^{43,44}.

61

62 Due to the successful HIV test and treat strategy globally, the prevalence of individuals
63 receiving ART has risen considerably¹⁶. Consequently, the number of HEU infants born to
64 mothers receiving ART has increased markedly^{45,46}, but despite expanded maternal use of

65 ART⁴⁷ or implementation of prevention-of-mother-to-child-transmission (PMTCT)
66 programmes⁴⁸, the risk of infection-related morbidity and mortality among HEU infants
67 remains high², particularly the risk of encapsulated bacterial infection^{7,9,49-51}. The immune
68 profile amongst HEU infants in this context is not well documented. We have therefore
69 addressed the question of whether HIV exposure and HHVs dysregulate infant immunity
70 and/or response to primary vaccination. By comprehensive cellular and serological
71 assessment, we show impaired monocyte phagosomal function, altered B cell homeostasis
72 and selective impairment of vaccine-induced anti-Hib antibody response in HEU babies less
73 than 6 months of age. These findings suggest acquired defects in innate and adaptive
74 immunity, heightened regulation of HEU immune responses, which may increase
75 susceptibility to invasive bacterial disease and pneumonia.

76

77 **Results**

78 **Participant characteristics.** We recruited two cohorts to evaluate the impact of HIV
79 exposure and herpes virus infection on immunity at birth and in early infancy. A birth cohort
80 comprised 34 HIV-infected and 44 HIV-uninfected pregnant women. A longitudinal infant
81 cohort comprised 43 HIV-infected and 61 HIV-uninfected mother-infant pairs, who were
82 followed at 3 timepoints, 5-9, 14-15 and 18-23 weeks of age, corresponding to the Malawian
83 routine infant vaccine schedule of: BCG at birth, then pentavalent vaccine at 6, 10 and 14
84 weeks.

85

86 In the birth cohort, two babies were excluded from the analysis due to death and HIV-
87 positivity detected by digital droplet PCR. HIV-infected pregnant women received ART
88 (Option B+) for an average of 18.7 (range 1-143) months, with a mean nadir CD4+ T-cell

89 count of 294 (range 8-892) and were more likely to have had an elective caesarean birth,
90 compared to HIV-uninfected pregnant women (Table 1).

91

92 In the longitudinal infant cohort, HIV-infected mothers had received option B+ for an
93 average of 9.28 (range 1-72) months at the time of enrollment and had a mean nadir CD4+ T-
94 cell count of 409 (range 159-823). There was no difference between maternal age or
95 breastfeeding status but mode of delivery was more often caesarean section in HIV-infected
96 mothers compared to HIV-negative mothers (Table 1).

97

98 **Impaired CD14⁺ monocyte function in HEU new-borns.** Monocytes are an important first
99 line of defence against invasive bacteria, particularly in early life, before the maturation of
100 adaptive immunity^{52,53} and are crucial in controlling bacterial pneumonia⁵⁴⁻⁵⁶. We used a
101 flow cytometry-based whole blood reporter bead assay⁵⁷ to assess monocyte function in cord
102 blood (Figure 1a-b; Supplementary Figure 1). First, we assessed the ability of monocytes to
103 internalise Alexa Fluor 405-labeled IgG-coated reporter beads at 1 hour post co-incubation,
104 as a proxy of uptake capacity. We showed that the proportion of monocytes that internalised
105 reporter beads was similar between HEU infants and HUU controls (Figure 1c). Second, we
106 assessed the phagosomal superoxide burst activity, an important component of intracellular
107 killing by phagocytes⁵⁸, and found that phagosomal superoxide burst activity was lower in
108 monocytes from HEU infants compared to HUU controls (Figure 1d). Third, we assessed the
109 phagosomal bulk proteolytic activity, an important intracellular protein degradation
110 mechanism that impacts antigen-presentation⁵⁹, and showed that the phagosomal bulk
111 proteolytic activity was lower in monocytes from HEU infants compared to HUU controls
112 (Figure 1e). Collectively, these data indicate altered monocyte phagosomal functional
113 capacity at birth in HEU new-borns.

114

115 **Inhibitory B cell phenotype and reduced T cell mitogen response in HEU new-borns.**

116 Having demonstrated altered monocyte phagosomal function which is part of innate

117 immunity in HEU new-borns, we next sought to investigate whether B and T cell subsets are

118 dysregulated. In the B cell compartment, we observed similar distributions of B cell subsets

119 between HEU and HUU new-born babies, including, CD10⁻CD21⁺CD27⁻ (naive), CD10⁻

120 CD21⁻CD27⁺ (resting memory), CD10⁻CD21⁺CD27⁺ (activated memory), CD10⁻CD21⁻

121 CD27⁻ (tissue-like memory) and CD10⁺CD27⁻ (immature transitional) B cells (Figure 2a).

122 However, we found a higher proportion of Fc-receptor like 4 (FcRL4⁺) expressing B cells in

123 HEU new-borns, but no statistically significant differences in the proportion of PD-1 or

124 CD95-expressing B cells, when compared to HUU controls (Figure 2b). FcRL4⁺ inhibits B

125 cell activation through the B cell receptor (BCR) and is a marker of B cell exhaustion in

126 chronically HIV-infected adults⁶⁰, which suggests increased B cell regulation in HEU new-

127 born babies⁶¹.

128

129 In the T cell compartment, we found that the proportion of naïve and memory, CD4⁺ and

130 CD8⁺ T cell subsets were similar between HEU new-borns and HUU controls (Figure 3a-b).

131 There were also no differences between the two groups in the proportion of CD57 or PD-1-

132 expressing CD4⁺ and CD8⁺ T cells (Figure 3c-d), which are classical markers of T cell

133 immune senescence and exhaustion in chronic HIV infection^{62,63}. IFN γ production in

134 response to tuberculin purified protein derivative (PPD) in an 18-hour ELISpot assay was

135 similar in HEU new-borns compared to controls. In this population BCG is received soon

136 after birth. However, IFN γ production in response to the selective T cell mitogen

137 phytohemagglutinin (PHA)⁶⁴ was reduced in HEU new-borns compared to controls (figure

138 3e), indicating selective regulation of T-cell responses.

139

140 **Persistent dysregulation of the B cell compartment in HEU infants.**

141 Having found an altered innate compartment and increased regulatory B cell phenotype at
142 birth, we then investigated the impact of HIV exposure on adaptive immunity in the first few
143 months of life in the longitudinal infant cohort. We found that the proportions of immature
144 transitional and tissue-like memory B cells were lower in HEU infants than HUU controls
145 (Figure 4a), two B cell subsets that are selectively dysregulated in HIV infection ^{65,66}.

146 However, as seen in the new-born cohort, the proportions of naïve and memory, CD4+ and
147 CD8+ T cell subsets, were similar between HEU infants and HUU controls (Figure 4a-b).

148

149 **Increased IFN γ production to PPD in a T-cell ELISpot assay in HEU infants**

150 To determine if T-cell responses were altered in HEU infants, we evaluated IFN γ spot
151 forming cells (SFCs) to tetanus toxoid (TT), hepatitis B (Hb) and purified protein derivative
152 (PPD) in an 18-hour T-cell ELISpot in infants aged 5-9 weeks of age. We observed increased
153 IFN γ SFCs/million PBMCs to PPD amongst HEU infants compared to HUU controls, but
154 similar Hb, TT and PHA responses between the two groups (Supplementary figure 5a). These
155 data indicate that HEU infants' antigen-specific responses to PPD following BCG
156 vaccination at birth have the potential to be greater in capacity than HUU infants.

157

158 **Impaired IgG antibody responses to routine pentavalent vaccination in HEU infants.** In

159 the longitudinal infant cohort, having demonstrated B-cell dysregulation, we interrogated
160 vaccine-induced memory B cell antibody responses to polysaccharide and protein antigens
161 that are in the Malawian infant primary vaccination series. This included PCV13 and
162 Pentavalent Vaccine (DPT-HepB-Hib) which protect against several important infant disease-
163 causing bacteria, we focused on: *Streptococcus pneumoniae* (13 serotypes) and *Haemophilus*

164 *influenza* type b (Hib), *Clostridium tetani* (tetanus toxoid) and *Corynebacterium diphtheriae*
165 (diphtheria toxoid).

166

167 Following 3 vaccine doses, we found lower anti-*Hib* and anti-diphtheria toxoid (DT) titers,
168 but similar anti-TT titers in HEU infants, compared to HUU controls (Figure 5a-c). In the
169 mothers of these infants, anti-*Hib* IgG and anti-TT IgG titres but not anti-DT titers were
170 lower in HIV-infected mothers than HIV-uninfected controls (Figure 5d-f).

171 Having shown the B cell compartment produces differential antigen specific
172 immunoglobulins to vaccine antigens, we next tested whether HIV exposure influences the
173 levels of vaccine-induced functional antibody. Using a Multiplex
174 Opsonophagocytosis Assay (MOPA), we measured opsonophagocytic activity of 13 vaccine
175 serotypes from the PCV13 (1, 3, 4, 5, 6A, 6B, 7F, 9V, 14, 18C, 19A, 19F, 23F) in infant sera.
176 We found no difference in the geometric mean opsonophagocytic index (GMOI) of 13
177 pneumococcal serotypes and geometric mean concentration (GMC) of serotype-specific IgG
178 titres, between HEU infants and HUU controls (Table 2).

179

180 **Evidence of HIV exposure in early infancy**

181 Next, we sought to ascertain evidence of HIV exposure as a driver of dysregulation in innate
182 and adaptive immunity of HEU new-borns by measuring HIV specific responses from birth
183 to infancy. We measured HIV Gag-specific responses in peripheral blood mononuclear cells
184 ⁶⁷ using an 18-hour *ex-vivo* IFN- γ ELISpot assay in both the HEU new-born and the
185 longitudinal infant cohorts. (Figure 6a; Supplementary Figure 3a) ⁶⁸⁻⁷⁰. Few Gag-specific
186 responses were detectable in cord blood of HEU new-borns (Supplementary Figure 5).
187 Consistent with previous studies ^{71,72}, there was detectable IFN- γ producing HIV Gag-

188 specific cell responses in approximately 50% of the longitudinal cohort of HEU infants
189 (Figure 6b).

190

191 **HEU infants have increased exposure to maternal-derived hCMV**

192 HEU infants are more frequently exposed to human herpes viruses (HHV) *in utero* and/or
193 perinatally than HUU infants^{73,74}, due to the high seroprevalence and reactivation of hCMV
194 and EBV in HIV-infected individuals and pregnant women⁷⁵⁻⁸⁰. We therefore sought to
195 determine the extent of immune-modulating HHV, hCMV and EBV infection in our
196 longitudinal infant cohort.

197

198 We found that anti-hCMV IgG titers were higher in sera from HEU infants than HUU
199 controls (Figure 6c), but hCMV PCR detection was similar (Figure 6d), indicating potential
200 differences in the pattern of exposure to hCMV but not increased infection. We then
201 measured hCMV in maternal breastmilk as a potential source of transmission or transfer of
202 viral products to the infants. We found that the proportion of mothers with an hCMV positive
203 PCR result in breast milk was higher in the HIV-infected mothers compared to HIV-
204 uninfected controls (Figure 6e). In contrast, we did not observe any statistically significant
205 differences between potential EBV exposure in HEU infants compared to HUU controls,
206 whether by EBV IgG ELISA (Figure 6f) or PCR (Figure 6g). Overall, these results
207 demonstrate that HHV (hCMV and EBV) infection are common in infancy, irrespective of
208 HIV-exposure status. High hCMV titres in HEU infants may indicate immune boosting from
209 breastmilk of HIV-infected women.

210

211 **Discussion**

212 HIV-exposed but uninfected infants are at an increased risk of a wide variety of infections
213 even in the era of universal access to maternal ART, but the underlying immunological basis
214 is not well understood ^{7,51}. We show altered monocyte phagosomal function, dysregulated B
215 cell homeostasis and selective impairment of vaccine responses in HEU infants within the
216 first 6 months of life. We also demonstrate evidence of HIV exposure and increased
217 likelihood of hCMV exposure in HEU infants. HIV and hCMV are immunomodulatory
218 viruses ⁸¹, so co-exposure to these two pathogens in early life may contribute to this immune
219 dysregulation. We postulate that the complexity, variable severity and/or persistence of this
220 immunological phenotype explain the variable clinical manifestations reported in HEU
221 infants ^{8,9,11,40,82-86}, which may depend on the duration and intensity of exposure to HIV and
222 other infectious co-factors.

223
224 The impaired monocyte phagosomal function in HEU new-borns highlights their potential
225 vulnerability to bacterial infection before the primary immunisation series. Monocyte
226 bactericidal activity requires uptake, reactive oxygen species (ROS) formation and
227 phagosomes-lysosomes fusion resulting in inhibition, killing and degradation of internalised
228 bacteria ^{87,88}. In our setting, the validated flow cytometer reporter assay of phagocyte function
229 which uses zymosan has shown poor immune function and superoxide burst activity in HIV-
230 infected adults with active tuberculosis (TB)⁸⁹. Monocyte functional impairment against
231 encapsulated bacteria has also been observed in “age-associated” inflammation, where
232 monocyte-activating cytokines TNF- α and IL-6 are augmented ⁹⁰. Similarly, increased
233 monocyte inflammatory markers, including sTNF-RI, IL-6, IP-10, oxLDL and sCD14 are
234 reported in HEU new-borns ⁸⁷; as well as enhanced pro-inflammatory cytokine secretion
235 following stimulation with diverse PAMPs at 6 weeks of age ⁹¹. Moreover, recent PBMC
236 transcriptomic profiling in HEU infants at 1-2 years of age, revealed down-regulated genes

237 (LCN2, CAMP, HP, MMP8, BPI, LTF) associated with neutrophil function⁹². It is therefore
238 plausible that the observed impaired monocyte phagosomal function is a consequence of an
239 inflammatory microenvironment in HEU infants, from an inflammatory maternal cytokine
240 milieu and/or exposure to HIV antigens that could explain their increased susceptibility to
241 bacterial infection including pneumonia¹⁴.

242 In line with the proposed inflammatory environment in HEU new-borns⁹³, we observed high
243 proportions of FcLR4 expressing B cells. In HIV-infected adults, B cells expressing the
244 inhibitory receptor FcLR4 are over-represented, an ‘exhausted’ B cell phenotype, that
245 displays poor B cell receptor mediated activation and antigen-specific antibody production in
246 chronic HIV infection^{60,94,95}. Additionally, in HEU infants at 6 to 14 weeks of age, we
247 observed low proportions of tissue-like memory (TLM) and immature-transitional B-cell
248 subsets. TLM and immature transitional B cells are augmented in HIV-infected adults,
249 occurring most profoundly during chronic HIV infection^{96,97}. The contraction of atypical
250 memory B cells in HEU infants may be indicative of dysregulated B cell homeostasis⁹⁸.

251 Importantly, our data presents evidence of increased exposure to HIV and hCMV in HEU
252 infants from maternal HIV and/or viral proteins, hCMV recrudescence and high PPD specific
253 IFN γ , that may promote B cell dysregulation in the first 2 months of life. PPD responses are
254 shown to be increased in *mycobacterium tuberculosis* (Mtb) sensitised mothers, which may
255 explain our findings⁹⁹, furthermore, others have described a bimodal response to BCG/PPD
256 (high/low) in HEU infants in our setting¹⁰⁰. Taken together, the mechanisms of B cell
257 dysregulation are likely distinct from those seen in chronic HIV infection
258 (hypergammaglobulinaemia)¹⁰¹, due to the lack of replicative virus and preserved CD4 T-
259 cells.

260

261 Altered B cell homeostasis is associated with impaired antibody responses during chronic
262 HIV infection ^{102–105}. Consistent with this observation, HIV-infected mothers in our cohort
263 exhibited lower anti-Hib and anti-TT antibody titers than HIV-uninfected mothers. In
264 agreement with maternal titers, we observed low anti-Hib titers in HEU infants. It is known
265 that HIV-infected children are at greater risk of vaccine failure compared to HIV-uninfected
266 children ^{106–108}. However, our observation is in contrast with studies conducted in South
267 Africa ¹⁰⁹ and Uganda ^{110,111}, who reported robust anti-Hib and anti-DT antibody titers in
268 HEU infants. In our setting the Pentavalent Vaccine (DPT-HepB-Hib) was used, in South
269 Africa it was (DTP-Hib and DTaP-IPV/Hib) ¹⁰⁹, and in Uganda (aP-HibCV and
270 DTwP/HBV/PRP-T) ^{110,111}. Differential vaccine immunogenicity is likely multifactorial,
271 influenced by persistent immune exposure to HIV proteins, the time to maternal ART use and
272 the unique burden of infectious co-factors that likely contribute to a microenvironment of
273 pro-inflammation. Furthermore, HIV proteins are reported to cause aberrant binding to
274 surface immunoglobulins ^{112–115}, which may interfere with specific antibody responses.
275 Consistent with previous observations ¹¹⁶, we observed that a relatively large number of HEU
276 infants mounted an IFN- γ response following stimulation with HIV Gag, however we did not
277 detect IFN- γ responses in HEU new-borns. Detection of HIV-specific T cell responses in
278 HEU infants was first described nearly 30 years ago ^{71,72}. Others have reported that HEU
279 infants have increased regulatory T cells (Tregs) that correlate with decreased T cell function
280 ²⁹ and have shown that depletion of Treg cells from the cord blood of HEU new-borns reveals
281 HIV-1-specific T responses ¹¹⁶. We also observed poor IFN- γ responses in cord blood of
282 HEU new-borns following stimulation with the T cell mitogen PHA (which crosslinks the
283 TCR and glycosylated surface proteins). Taken together, these data point towards HIV
284 exposure as a possible driver of increased regulation/inhibition of T cell activation at birth.
285

286 Our study has some limitations, including use of a surrogate assay to measure monocyte
287 function and the limited number of assays we could perform on each sample. Additionally,
288 our cohorts were too small to establish direct associations with immune dysregulation and
289 clinical presentation of disease.

290

291 In conclusion, we show altered monocyte phagosomal function, dysregulated B cell
292 homeostasis and selective impairment of vaccine antibody responses in HEU infants within
293 the first 6 months of life. This period of vulnerability likely contributes to increased
294 susceptibility to disease-causing bacteria that commonly cause life-threatening illness such as
295 pneumonia in HEU infants.

296

297 **Methods**

298 **Study Design and population.** The study was conducted in Southern Malawi, at Ndirande
299 Health Centre (NHC) (a primary healthcare facility in the city of Blantyre) and at Queen
300 Elizabeth Central Hospital (QECH) (a tertiary teaching hospital in the city of Blantyre). We
301 recruited the infant cohort in two contiguous groups that were followed longitudinally. The
302 first group were aged 5-9 weeks (pre-1st vaccine dose) who were followed up to age 14-15
303 weeks (post-2nd vaccine dose) and the second group were aged 14-15 weeks (post-2nd vaccine
304 dose) who were followed up to 18-23 weeks of age (post-3rd vaccine dose). We recruited
305 pregnant women in the early stages of labour at QECH maternity ward and subsequently their
306 babies at birth (termed birth cohort). Participating mothers were healthy, asymptomatic adults
307 (>18 yr) comprising HIV-infected and HIV-uninfected volunteers. HIV testing was
308 performed on whole blood using two commercial point-of-care rapid HIV test kits,
309 Determine HIV 1/2 kit (Abbott Diagnostic Division, Abbott Park, IL) and Unigold HIV 1/2
310 kit (Trinity Biotech Inc., Bray, Ireland). HIV-infected participants received first line ART

311 (Option B+ (Lamivudine, Tenofovir DF and Efavirenz (3TC/TDF/EFV)) at any point during
312 pregnancy and had a CD4+ T-cell count performed. All HEU babies received single dose
313 nevirapine at birth and co-trimoxazole until 6 months of age. Exclusion criteria for the study
314 participants were current or past history of smoking, heart disease, tuberculosis, high blood
315 pressure, drug use, syphilis, severe anaemia (haemoglobin <8 g/dl), placental abnormalities,
316 infant death and existing comorbidities. All babies received Bacille Calmette Guerin (BCG)
317 vaccine at birth. Written informed consent was obtained from all participants prior to
318 recruitment. Ethical approval was obtained from the University of Malawi College of
319 Medicine Research and ethics committee (COMREC), Blantyre, Malawi, protocol numbers
320 P.11/11/1140, P.06/11/1088.

321

322 **Sample collection and processing.** To maximise the number of samples we were able to
323 collect from very young infants, we collected 5ml of venous blood from the infants, at 5-9,
324 14-15 and 18-23 weeks of age following attendance at the vaccination clinic for pentavalent
325 DPT-HepB-Hib immunisation. Participants who did not complete their vaccine course were
326 excluded from the analysis. From their mothers, 10ml of venous blood were collected only at
327 the first visit and 3mls of breastmilk at all three time points. We collected up to 40ml cord
328 blood from the umbilical vein into sodium heparinised tubes using a 50ml syringe from the
329 baby interface of the placenta immediately after birth. Whole blood was kept at RT for no
330 longer than 2 hours from collection to processing. Peripheral blood mononuclear cells were
331 isolated by density centrifugation. Diluted whole blood was layered on top of Histopaque
332 Ficoll gradient (Sigma-Aldrich, UK) at a ratio of 2:1 and centrifuged (900g, 24 °C for 30
333 minutes). The PBMC fraction was removed using a Pasteur pipette and washed immediately
334 in HBSS (Sigma Aldrich, UK) by centrifugation (500g, 4 °C for 5 minutes). Cells were re-
335 suspended in 2mL of complete media ((RPMI 1640 plus (Sigma-Aldrich, UK) with 10mM

336 HEPES (Sigma-Aldrich, UK), 1% v/v penicillin, 1% V/V streptomycin (Sigma Aldrich) and
337 2mM L-glutamine (Sigma-Aldrich, UK)), then agitated to ensure complete mixing and
338 counted using a haemocytometer with 1:10 trypan blue (Sigma Aldrich, UK) staining to
339 confirm viability. Plasma was separated by centrifugation at 1500rpm for 10 minutes,
340 aspirated, aliquoted and stored at -80 for later use. Breastmilk samples were collected by
341 hand expression, fractionated into lipid and aqueous phase and stored at -80. Due to
342 limitations in the volume of blood collectable from very young babies and limited cell
343 numbers, not all the assays were performed on samples obtained from every participant.

344

345 **HIV testing.** New-borns and infants qualitative HIV DNA PCR tests were performed in
346 batches of 23. Total RNA was isolated from 0.5×10^6 cells using AMPLICOR HIV-1 DNA
347 test, V1.5 (Roche, USA) according to the manufacturer's instructions.

348 Three HIV-RDT kits, from two separate manufacturers (Unigold™ and Determine™) were
349 used to confirm the presence or absence of HIV specific immunoglobulins (Ig) in maternal
350 peripheral blood. Cord blood mononuclear cells (CBMCs) from were stored in 500ul of
351 RNAlater and analysed at UCL by digital PCR as described elsewhere ¹¹⁷.

352

353 **Maternal CD4 counts.** Peripheral blood CD4 T-counts and full blood count (FBC) were
354 performed at the Malawi-Liverpool Wellcome Trust Clinical Research Programme
355 Diagnostic Laboratory on an Hmx analyser (Beckman Coulter, USA) using a standardized
356 protocol.

357

358 **Phenotypic analysis.** Multicolour flow cytometry analysis was performed on whole blood
359 (WB). Samples were stained with the following fluorochrome conjugated antibodies, anti-
360 CD14 Phycoerythrin Cyanine-7 (PECy7), anti-CD3 Allophycocyanin-H7 (APC-H7), anti-

361 CD4 Pacific Blue (PB), anti-CD8 Fluorescein (FITC), anti-CD8 (PECY7), CD45RA
362 Phycoerythrin (PE), CD45RA PECY5, CCR7 Allophycocyanin (APC), anti-CD19 (APC),
363 anti-CD19 Peridinin-Chlorophyll-Protein (PERCP), anti-CD27 (PE), , CD10 PE-Cy7, CD21
364 FITC, CD27 APC-Cy7, CD95 e450, FcLR4 PE, CD57 FITC, PD-1 APC, PD-1 PE
365 (Supplementary Tables 1 and 2, Gating strategy supplementary figure 2). Samples were
366 acquired on Beckman Coulter Cyan ADP and analyses were performed using FlowJo Version
367 7.6.5 and 10.5 software (Treestar).

368

369 **Measurement of monocyte phagosomal enzymatic activity.** Phagosomal oxidative burst
370 and bulk proteolytic function in monocytes was measured using a flow cytometry–based
371 reporter bead assay as described previously^{57,118,119}. Briefly, 3µm diameter silica beads were
372 derivatized with the calibration fluorochrome (Alexa Fluor 405-SE) and the fluorogenic
373 reporter substrates Oxyburst Green succinimidyl ester (Oxybeads) (Molecular Probes,
374 Eugene, OR) for superoxide burst, or DQ Green bovine serum albumin (DQ-beads)
375 (Molecular Probes, Eugene, OR) for bulk proteolysis. When the beads are internalised by
376 monocytes the fluorescence intensity is proportional to the degree of activity in the
377 phagosome, which provided a readout of phagosomal enzymatic activity. The readout for the
378 assay is reported as the ratio of the median fluorescent intensity of the reporter fluorochrome
379 at 60mins:10mins and 240mins:10mins for oxidative burst and bulk proteolysis, respectively.
380 The uptake cut-off was 35% in the assay.

381

382 **T cell IFN γ ELISpot.** 2x10⁶ PBMCs were stimulated in an 18-hour IFN- γ T cell ELISpot;
383 plates were coated with purified anti-human interferon- γ monoclonal antibody (α human-
384 IFN- γ -mAb) 1-D1K (Mabtech, UK) 1:66 at a concentration of 3.78µg/mL in sterile PBS. The
385 enumerated IFN- γ producing cells after antigen stimulation were used as an index of effector

386 memory T cell responses, as previously described ¹²⁰. Data were reported after deducting 2x
387 the value of the negative well. Stimulating antigens were: Phaseolus vulgaris lectin (PHA)
388 5ug/ml (NIBSC, UK), purified protein derivative (PPD) 10ug/ml (Statens serum institute,
389 Denmark) and HIV-1 consensus C gag 15-mer peptides (GAG peptide) 10ug/ml (NIH AIDS,
390 USA)¹²⁰

391

392 **Human cytomegalovirus PCR** . Real time PCR was used to detect hCMV in HIV-infected
393 and uninfected maternal breast milk and plasma. The results were based on a standard curve
394 constructed using an in-house plasmid previously calibrated against quality controls for
395 molecular diagnostics and external quality assessment panels (Hamprecht et al. 1998). The
396 positive control was assessed again and an expected value of 2,500 copies seen with results
397 read on the ABI Prism 7500 (Thermofisher, UK). The amplification plot was assessed against
398 a standard slope range of -3.10 to -3.60 and a R² value > 0.9.

399

400 **Detection of Cytomegalovirus specific IgG and IgM antibodies.** hCMV specific IgM in
401 plasma was measured using a commercial ELISA kit (IBL International, Hamburg) according
402 to manufacturer's instructions. A semi-quantitative, in-house hCMV IgG assay was used at
403 the laboratories in the University of Birmingham, UK. Plasma was diluted 1/4 in a dilution in
404 a 1:1:1 mix of plasma from three healthy donors, the top concentration was assigned an
405 arbitrary unit of 1000. The unknown samples were related to the standard curve and a titre
406 calculated. Briefly, Nunc 96-well plates Maxisorb (Fisher Scientific # 442404) were coated
407 with 50µL UV activated hCMV-lysate (1:4000) and mock-lysate (1:4000) in carbonate-
408 bicarbonate buffer pH 9.6 (sigma capsules), then covered with parafilm and incubated at 4°C
409 overnight in the fridge. The following day, plates were washed three times in 200µL (PBS +
410 0.05% Tween20), 100µL of samples were added 1:600 in dilution buffer (PBS + 1%BSA +

411 0.05% Tween20), blank dilution buffer, and standards, then incubated for 1h at room
412 temperature (RT). Plates were washed again three times, then 100µL of the secondary
413 antibody, anti-human IgG-HRP (1/8000 dilution in PBS+1% BSA+0.05% Tween20) goat
414 anti- human IgG (Southern Biotech #2040-05). Plates were incubated and washed again as
415 described, after which 100µL of tetramethyl benzidine (TMB-solution) (Tebu-Bio) was added
416 for 10 min at RT. The reaction was stopped with 100µL 1M HCl and plates were read at
417 405nm (Biotek instrument).

418

419 **Sandwich enzyme-linked immunosorbent assay to detect IgG specific to vaccine**

420 **antigens.** In an in-house ELISA, TT or DT (both NIBSC, UK) were diluted to 0.5 Lf/mL or
421 Hib capsular polysaccharide 0.1µg/mL in 10 mL carbonate coating buffer (0.015 M Na₂CO₃,
422 0.035 M NaHCO₃ pH9.6); 100 µL per well of the solution was pipetted into a 96-well flat
423 bottom Maxisorp plate. Plates were incubated overnight at 4 °C then washed seven times with
424 PBS 0.05% Tween. 50 µl goat anti-human alkaline phosphatase-conjugated secondary
425 antibodies (Southern Biotech, UK) were diluted to 1ug/mL in PBS 0.05% Tween 2% BSA
426 and added to each well. The plates were incubated for 1 h at 37 °C, then washed seven times
427 with PBS 0.05% Tween. 100 µL of Sigma-fast p-nitrophenyl phosphate substrate was added
428 to each well (Sigma, UK). A standard curve was generated using a set of 2- fold dilutions of a
429 standard pooled serum (NIBSC, UK). Optical density was measured (without acid stopping
430 the reaction) after 10 min using an ELISA plate reader (Biotek, UK) set at 405nm and
431 SoftMax Pro software ¹²¹.

432

433 **Multiplexed opsonophagocytosis killing assay and serotype-specific IgG .** Sera from 20

434 infants were sent on dry ice to the UCL Great Ormond Street Institute of Child Health (UCL;
435 United Kingdom). Infants had received 3 doses of Prevnar (PCV13) at 6, 10, and 14 weeks of

436 age. Sera were stored at -20°C until analysis. Analyses were performed at the World Health
437 Organization pneumococcal reference laboratory (University College London, United
438 Kingdom). Immunoglobulin G (IgG) serum concentrations specific for the 13 vaccine
439 serotypes (1, 3, 4, 5, 6 A, 6B, 7F, 9V, 14, 18C, 19A, 19F, and 23F) were measured using an
440 enzyme-linked immunosorbent assay (ELISA) after adsorption with cell-wall and 22F
441 polysaccharides to increase the assay specificity¹²². A standardized opsonophagocytic assay
442 (OPA) was used to measure functional antibodies against the same serotypes¹²³. The OPA
443 titre was defined as the reciprocal of the lowest serum dilution that induces $\geq 50\%$ bacterial
444 cell death compared to the assay control.

445

446 **Statistical analysis.** Statistical analysis and graphical presentation were performed using
447 Prism 7/8 (GraphPad Software, San Diego, USA) and Python (Python Software Foundation)
448 was used to calculate summary statistics. Demographic and clinical characteristics were
449 compared using Mann-Whitney-U for continuous and Fisher's exact tests or χ^2 for discrete
450 variables. ELISpot data were reported as subtracted 2 x background. Serotype-specific
451 opsonophagocytic indexes (OIs) were reported using geometric means and 95% confidence
452 intervals. The OIs were classified as being positive or negative based on the current
453 recommended cut-off value of < 8 (negative) and ≥ 8 (positive). Results are reported as
454 median and IQR as stated.

455

456 **Acknowledgments**

457 The authors are grateful to the participants for their willingness to participate in this study.
458 This work was supported by a studentship from the Franklin Adams Trust and a project grant
459 from the Wellcome Trust . The Malawi-Liverpool-Wellcome Trust Clinical Research
460 Programme was supported by a strategic award from the Wellcome Trust.

461

462 **Author contribution**

463 L.A, A.F, R.S.H, S.R.J, D.M contributed to study design. L.A, A.B, B.F, R.K, D.H.B, D.G,

464 P.M, D.M performed the experiments. W.N recruited and monitored the participants. L.A,

465 K.C.J analysis and interpretation. H.M, D.M, A.F., K.C.J, R.S.H, reviewing the manuscript

466 L.A, K.C.J, S.R.J, A.F, R.S.H, final approval.

818

819 Abbreviations: GMOI (geometric mean opsonophagocytic index), GMC (geometric mean concentration) 95% CI (95% confidence interval),

820 PCV13 (pneumococcal conjugate vaccine 13) The geometric mean opsonic index (GMOI) and 95% confidence intervals (CI) of results are

821 reported for MOPA (HUU n = 11, HEU n = 9) ; the serotype-specific IgG geometric mean concentration (GMC) (HUU n = 11, HEU n = 8)

822 for all PCV13 serotypes (1, 3, 4, 5, 6 A, 6B, 7F, 9V, 14, 18C, 19A, 19F, and 23F) are reported, less than 8 was reported as no response.

823

824 **Figure Legends**

825 **Figure 1. Monocyte phagosomal functional capacity in HEU new-borns and HUU**

826 **controls.** The proportion of CD14⁺ cells that performed **a)** phagosomal superoxide burst
827 activity, **b)** phagosomal bulk proteolytic activity, **c)** and that were associated with beads, **d)**
828 the phagosomal superoxide burst activity index and **e)** the phagosomal bulk proteolytic
829 activity index. The readout for the assay are reported as the median fluorescent intensity of
830 the reporter fluorochrome at 60mins:10mins and 240mins:10mins for oxidative burst and
831 bulk proteolysis, respectively. The activity index was calculated using a ratio of the reporter
832 fluorochrome over the the calibration fluorochrome. Only individuals with an uptake of
833 greater than $\geq 30\%$ were used in the phagosomal analysis. Data are presented as medians and
834 analysed using Mann Whitney U test (HUU, n=16; HEU, n=12).

835

836 **Figure 2: Characterisation of B cell immune profiles in HEU and HUU new-borns**

837 Cord blood was stained with the following fluorochrome-conjugated antibodies, anti-CD19
838 APC, anti-CD10 PE-Cy7, anti-CD21-FITC and anti-CD27 APC-CY7. Singlets were defined
839 using FSC-A vs. FSC-H parameters and lymphocytes were gated using SSC-A and FSC-A. B
840 cells were then gated using CD19 against SSC-A. **a)** The proportion of B cell subsets were
841 clasified using CD10, CD21 and CD27 as follows, **b)** CD10⁻CD21⁺CD27⁻ (naive), CD10⁻
842 CD21⁻CD27⁺ (resting memory), CD10⁻CD21⁺CD27⁺ (activated memory), CD10⁻CD21⁻
843 CD27⁻ (tissue-like memory) and **c)** CD10⁺CD27⁻ (immature transitional).
844 **d-e)** Expression of CD95e450, FcLR4 PE and PD-1 APC (exhausted and activatory inhibited
845 B-cells) were gated as a proportion of CD19⁺ cells.
846 Data are presented as medians [IQR] and analysed using Mann Whitney U test (HUU n=42,
847 HEU n=18).

848

849 **Figure 3. Characterisation of T cell subsets in HEU and HUU new-borns.** a) Whole cord
850 blood was stained with the following fluorochrome-conjugated antibodies, anti-CD3
851 APCCY7, anti-CD4 Pacific Blue, anti-CD8-FITC, anti-CCR7 APC and anti-CD45RA
852 PECY7. Singlets were defined using FSC-A vs. FSC-H parameters and lymphocytes were
853 gated using SSC-A and FSC-A. T cells were then gated using CD3 against SSC-A, then a
854 CD4 versus CD8 plot was used to separate the two main T cell subsets. b) CD4⁺ and CD8⁺ T
855 cell subsets were classified using CCR7 and CD45RA as follows CCR7-CD45RA⁻ (effector
856 memory), CCR7⁺CD45RA⁻ (central memory), CCR7⁺CD45RA⁺ (naïve) and CCR7⁻
857 CD45RA⁺(terminally-differentiated).
858 c) Whole cord blood was stained with the following fluorochrome-conjugated antibodies,
859 anti-CD3 APCCY7, anti-CD4 Pacific Blue, anti-CD8-PECY7 and CD57 FITC, PD1-PE.
860 Singlets were defined using FSC-A vs. FSC-H parameters and lymphocytes were gated using
861 SSC-A and FSC-A. T cells were then gated using CD3 against SSC-A, then a CD4 versus
862 CD8 plot was used to separate the two main T cell subsets. d) CD4⁺ and CD8⁺ T cell subsets
863 were classified using CD57 (senescent) and PD-1 (exhausted). (HUU, n =36; HEU, n =25). e)
864 Isolated CBMCs were incubated with PHA or PPD for 18 hours and IFN- γ producing cells
865 were detected on a 96-well microtitre ELISpot plate. The frequency of SFCs/million CBMCs
866 are plotted for all subjects. (HUU, n =34; HEU, n =22) Data analysed using Fisher's exact
867 test.

868

869 **Figure 4: Characterisation of B cell and T cell subsets in HEU and HUU infants**

870 Cord blood was stained with the following fluorochrome-conjugated antibodies, anti-CD19
871 APC, anti-CD10 PE-Cy7, anti-CD21-FITC and anti-CD27 PE. Singlets were defined using
872 FSC-A vs. FSC-H parameters and lymphocytes were gated using SSC-A and FSC-A. B cells
873 were then gated using CD19 against SSC-A. a) The proportion of B cell subsets were

874 classified using CD10, CD21 and CD27 as follows, **b)** CD10⁻CD21⁺CD27⁻ (naive), CD10⁻
875 CD21⁻CD27⁺ (resting memory), CD10⁻CD21⁺CD27⁺ (activated memory), CD10⁻CD21⁻
876 CD27⁻ (tissue-like memory) and **c)** CD10⁺CD27⁻ (immature transitional).
877 Whole blood was stained with the following fluorochrome-conjugated antibodies, anti-CD3
878 APCH7, anti-CD4 Pacific Blue, anti-CD8-FITC, anti-CCR7 APC and anti-CD45RA PE.
879 Singlets were defined using FSC-A vs. FSC-H parameters and lymphocytes were gated using
880 SSC-A and FSC-A. T cells were then gated using CD3 against SSC-A, then a CD4 versus
881 CD8 plot was used to separate the two main T cell subsets. **d-e)**CD4⁺ and CD8⁺ T cell
882 subsets were classified using CCR7 and CD45RA as follows CCR7⁻CD45RA⁻ (effector
883 memory), CCR7⁺CD45RA⁻ (central memory), CCR7⁺CD45RA⁺ (naïve) and CCR7⁻
884 CD45RA⁺(terminally-differentiated).
885 Data are presented as medians [IQR] and analysed using Mann Whitney U test (HUU n=42,
886 HEU n=31).

887

888 **Figure 5. Infant and maternal antibody responses.** Preceding and following Penta-
889 DTwPHibHepB vaccination we measured vaccine titers using an ELISA to **a)** anti-Hib IgG
890 **b)** anti-TT IgG **c)** anti-DT IgG in infant serum at 5-7 (HUU, n=50; HEU n=39), 14-15 (HUU,
891 n=22; HEU, n=27) and 18-23 (HUU, n=25; HEU, n=19) weeks. HIV- uninfected (n=61) and
892 HIV-infected (n=43) and maternal titres for **d)** anti-*Hib* IgG **e)** anti-TT IgG **f)** anti-DT IgG
893 are depicted. Blue circles are controls and red are HEU infants or HIV-infected mothers.
894 Green dotted horizontal line represents cut-off for protective titers. Data are presented as
895 medians and analysed using Mann Whitney U test. Minimum putative protective titres are
896 0.15ug/mL (passive) and 1.0ug/mL (acquired) for *Hib*¹²⁴, and 0.01IU/mL for TT¹²⁵and DT
897 ¹²⁶.

898

899 **Figure 6: Infant exposure to immune modulating viruses HCMV and HIV**

900 **a)** Detection of Gag-specific T-cells by T-cell ELISPOT assay in HUU and HEU infants, and
901 ART naïve/experienced HIV-infected adults . Isolated PBMCs were incubated with 15-mer
902 Gag peptide pool, PHA as a positive control or RPMI media as a negative control. IFN- γ
903 producing cells were detected on a 96-well microtitre ELISpot plate. **b)** The frequency of
904 SFCs/million PBMCs are plotted for all subjects. Data analysed using Fisher's exact test
905 (HUU, n =22; HEU, n=34; HIV+ART+, n=17; HIV+ART-, n=8). **c)** Plasma anti-CMV IgG
906 was measured in infants at 5-15weeks of age and assigned an arbitrary titer; blue circles are
907 HUU controls and red circles are HEU. Data are presented as medians [IQR] and analysed
908 using Mann Whitney U test (HUU n=57, HEU n=42). The proportion of **d)** HUU and HEU
909 infants and **e)** HIV-infected and uninfected mothers with RT-PCR detected CMV DNA in
910 their oropharangeal throat swab and breast milk respectively, (HIV- n=23, HIV+ n=35). The
911 proportion of **f)** HUU and HEU infants who were seropositive for anti-EBV IgG in their
912 plasma (HUU n=57, HEU n=42) and **g)** mothers who had detectable EBNA4 protein by RT-
913 PCR, (HIV- n=23, HIV+ n=35). Data analysed using Fisher's exact test and effective size
914 reported as a relative risk.

915

916

917 **Supplementary Figures**

918 **Supplementary Figure 1: Gating strategy to detect monocyte phagosomal functional**

919 **capacity at birth.** Singlets were defined using FSC-A vs. FSC-H parameters and
920 lymphocytes were gated using SSC-A and CD14 PE-CY7. Then FSC-A vs. AF405 to gate
921 cells with beads. The readout for the assay are reported as the median fluorescent intensity of
922 the reporter fluorochrome at 60mins:10mins and 240mins:10mins for oxidative burst and
923 bulk proteolysis, respectively. The activity index was calculated using a ratio of the reporter

924 fluorochrome over the the calibration fluorochrome. Only individuals with an uptake of
925 greater than $\geq 30\%$ were used in the phagosomal analysis.

926

927 **Supplementary Figure 2: Gating strategy to characterise B cells.** a) Blood was stained
928 with the following fluorochrome-conjugated antibodies, anti-CD19 APC, anti-CD10 PE-Cy7,
929 anti-CD21-FITC and anti-CD27 PE. Singlets were defined using FSC-A vs. FSC-H
930 parameters and lymphocytes were gated using SSC-A and FSC-A. B cells were then gated
931 using CD19 against SSC-A. The following populations were determined: CD10⁻
932 CD21⁺CD27⁻ (naive), CD10⁻CD21⁻CD27⁺ (resting memory), CD10⁻CD21⁺CD27⁺ (activated
933 memory), CD10⁻CD21⁻CD27⁻ (tissue-like memory) and c) CD10⁺CD27⁻ (immature
934 transitional). b) Blood was stained with CD19 PERCP, anti-CD10 PE-Cy7, anti-CD21-FITC
935 and anti-CD27 APCCY7, FcRL4 PE, CD95e450 and CD27 APCCY7 to determine B cells
936 expressing inhibitory markers.

937

938

939 **Supplementary Figure 3: IFN- γ producing cells to HIV protein GAG at birth**

940 A 15-mer GAG peptide pool was used to stimulate isolated CBMCs from cord blood in an
941 18hour T cell EliSpot assay. IFN- γ producing cells were detected on a 96-well microtitre
942 ELISpot plate. a) The frequency of GAG SFCs/million CBMCs are plotted for all subjects.
943 Data analysed using Fisher's exact test (HUU, n =35; HEU, n=23).

944

945 **Supplementary Figure 4: Gating strategy to characterise T cell subsets.** a) Whole blood
946 was stained with the following fluorochrome-conjugated antibodies, anti-CD3 APCH7, anti-
947 CD4 Pacific Blue, anti-CD8-FITC, anti-CCR7 APC and anti-CD45RA PE. b) Cord blood
948 was stained with the following fluorochrome-conjugated antibodies, anti-CD3 APCY7, anti-

949 CD4 Pacific Blue, anti-CD8-PECY7, anti-CCR7 APC and anti-CD45RA PECY5, PD-1 PE
950 and CD57 FITC.
951 Singlets were defined using FSC-A vs. FSC-H parameters and lymphocytes were gated using
952 SSC-A and FSC-A. T cells were then gated using CD3 against SSC-A, then a CD4 versus
953 CD8 plot was used to separate the two main T cell subsets. FMO were used to determine
954 gating. CD4⁺ and CD8⁺ T cell subsets were classified using CCR7 and CD45RA as follows
955 CCR7-CD45RA⁻ (effector memory), CCR7⁺CD45RA⁻ (central memory), CCR7⁺CD45RA⁺
956 (naïve) and CCR7⁻CD45RA⁺(terminally-differentiated).

957

958 **Supplementary Figure 5: IFN- γ producing cells to vaccine antigens in HEU and HUU**
959 **infants**

960 Detection of IFN- γ producing cells using a T-cell ELISPOT assay in HUU and HEU infants..
961 Isolated PBMCs were incubated with either PPD, TT, Hb or PHA as a positive control or
962 RPMI media as a negative control for 18 hours. IFN- γ producing cells were detected on a 96-
963 well microtitre ELISpot plate. **a)** The frequency of SFCs/million PBMCs are plotted for all
964 subjects. Data analysed using Fisher's exact test (HUU, n =22; HEU, n=34).
