19

20 **Text**

21 **Summary text**

22 **Historically, Sir Isaac Newton, with a great perspective of geometry, analysed an elliptical**
23 **orbit derived from Kepler's primary astronomical data analysis, and the sir elicited the theory of**
24 **gravitation. Namely, secondary analysis with geometry was an essential step in physics. Then, with a**
25 **geometrical perspective, a re-analysis of a chart in the figure is also practical in biomedicine?**
26 **Nowadays, some image-checking AI detects research misconduct but not for useful, latent findings¹.**
27 **Taking our concept one step further, we focused on a geometrical meaning of the confidence interval**
28 **error bar. As an exploratory data analysis know-how in a figure of meta-regression analysis, we**
29 **conceived a method based on recognising geometrical patterns (layered hyperbolic shapes) suspected of**
30 **overlapping subgroups. Here we show the result that we applied our ideas to the traveller's thrombosis**
31 **(economy class syndrome) and coronavirus disease 2019 (COVID-19), both of which were suspected of**
32 **having overlooked information from many controversy²⁻²¹. Our analysis implied two S-curve types of**
33 **risk increasing during a flight in the traveller's thrombosis. Also, our analysis demonstrated overlooked**
34 **cyclic patterns on the onset of thrombosis. This result suggests a strong relationship between travel and**
35 **starting oral contraceptives (e.g., honeymoon and starting birth control oral contraceptives), which**
36 **means that risk diversification might allow more safe use of oral contraceptives. In the COVID-19, our**
37 **analysis demonstrated unrecognised scatter plot patterns on cardiac biomarkers, which may serve**

38 **studies for pathophysiology in COVID-19 patients. Regarding the above findings, pattern recognition of**
39 **hyperbolic shapes can contribute to a significant discovery in data mining.**

40

41 **Main text**

42 Recently, software improvements have allowed us to make a beautiful chart, but the understanding
43 chart is required²². As readers of a scientific article, we took the idea of "reading a chart carefully" one step
44 further and made a question that "something new exploratory data analysis (data mining) method assisted us
45 to find important knowledge from previously published figures?". In addition, although statistics based on
46 probability theory have applied the mathematical method to biomedicine (e.g., P-value), we turned our
47 attention to the viewpoint of geometry regarding its importance in history.

48 Subsequently, we were interested in a research field, traveller's thrombosis, in which many
49 controversies seemed to be associated with something overlooked (**Supplementary discussion 1: history of**
50 **traveller's thrombosis**). In the literature review, we focused on a figure that showed a result of meta-
51 regression analysis (Chandra et al., *Ann Intern Med.* 2009;151(3):180-90., Figure 3)⁷. In this figure, we saw a
52 geometrical shape (layered hyperbolic shapes) that seemed to be formed by overlapping two subgroups (**Fig. 1**
53 **a-d, Fig. 2, a**).

54 Through those trains of thought, we conceived a methodological process based on our basic concept
55 that approaching biomedical data from geometry was essential for exploratory data analysis. As know-how,

56 here we propose a kind of pattern recognition, which is searching for layered hyperbolic patterns in a figure
57 showing a result of meta-regression analysis.

58 To validate our ideas, we worked on consecutive exploratory data analyses, such as Analysis 1 (1A,
59 1B) and Analysis 2, setting a working hypothesis that the shape formed by multiple subgroups for **(overall**
60 **study framework is shown in Extended Data Fig. 1).**

61

62 **Numerical Experiment**

63 Considering theoretical consideration and numerical experiment, we constructed three mathematical
64 formulas for fitting hyperbolic patterns to data (**see Fig. 1 & Methods**). The numerical experiment indicated
65 that a U-shaped curve formed by the end of the confidence limit could be approximated by a parabola (**Fig. 1,**
66 **c).**

67

68 **Analysis 1A (dataset: Chandra et al.)⁷**

69 To assess eligibility for regression analysis, we reviewed a dataset, which was consisted of four
70 study data gathered by Chandra et al.⁷ for meta-regression analysis (Martinelli et al., 2003; Parkin et al., 2006;
71 Cannegieter et al., 2006; Kuipers et al., 2007)²³⁻²⁶. In this assessment, two study data (Martinelli et al., 2003;
72 Cannegieter et al., 2006)^{23,25} were judged inappropriate and excluded. Also, the odds ratio reported by Parkin
73 et al.²⁴ was suspected to be affected by a miscalculation, but qualitatively, it could only be used (**see Extended**
74 **Data Fig. 1 & Methods**).

75 In a part of the original dataset (Parkin et al., 2006 & Kuipers et al., 2007)^{24,26}, layered hyperbolic
76 patterns appeared and applied regression analysis with the above three formulas. The inflexion points of the S-
77 curves (centres of distributions) were 7.1 hours and 11.8 hours, respectively (**Fig. 2, b**).

78 Notably, we observed an overlooked cyclic pattern in the figure reported by Cannegieter et al²⁵
79 during the data review process. The cycle was 27.4 days (**Extended Data Fig. 2**). They did not mention this
80 wave pattern, and this notable oversight allowed to be accounted for by an inappropriate 3-dimensional graph
81 that disrupted human visual recognition (**Fig. 2, c, d, & Extended Data Fig. 2**).

82

83 **Analysis 1B (dataset: Philbrick et al.)⁴**

84 Considering that only a few data were available for the first analysis, to validate the first result, we
85 performed a similar analysis using another dataset, which was gathered by Philbrick et al. for a systematic
86 review. As a preparation, we conducted a data review to confirm eligibility for regression analysis (**see**
87 **Extended Data Fig. 1**). Then, only S-curves were applied because the dataset did not contain risk ratio data,
88 and hyperbolic shapes could not be fitted (for the details, see Methods). In this analysis, we found that two
89 inflexion points of S-curves were divided similarly to the first analysis (< 10 hours, > 10 hours) in the
90 stratified datasets by pulmonary embolism (PE) and deep vein thrombosis (DVT). The inflexion point of PE
91 was about 9.2 hours, and the point of DVT was about 12.1 hours, respectively (**Extended Data Fig. 3**).

92 Additionally, we found that unrecognised periodic pattern in the data reported by Clérel and
93 Caillard²⁷ during the data review, which was suspected to be the effect of circadian rhythm (**Extended Data**

94 **Fig. 4).** We also found a post-travel cyclic pattern in the Kelman et al.²⁸ same cases as Cannegieter et al²⁵. The
95 wave was less clear than the wave observed in the data reported by Cannegieter et al²⁵. In the waveform, there
96 was a raw-risk period just before 90 days. In this data, there was an uptrend (**Extended Data Fig. 5**).

97 Furthermore, we found a correlation between the stepped stages of increasing PE patients and the
98 issuance of the guidelines²⁹⁻³² for preventive hormone replacement therapy (HRT) to a menopause woman in a
99 figure reported by Clérel and Caillard²⁷ (**Extended Data Fig. 6**).

100

101 **Analysis 2 (dataset: COVID-19)³³**

102 Considering the above two analysis results, we decided to apply our ideas to the current complex
103 COVID-19 pandemic problem to find some overlooked things because there was some controversy about the
104 COVID-19 related thrombosis. This situation was similar to that of the traveller's thrombosis.
105 (**Supplementary discussion 2: research situations of COVID-19 related thrombosis**), and we started this
106 analysis under the inspiration from the famous mathematician Polya who stated that solving a similar problem
107 helped us solve a more difficult problem³⁴.

108 One of us (KK) searched for the layered hyperbolic pattern using a search engine and extracted a
109 figure reported by Matsushita et al.³³ (**Fig. 3, a-c**). After evaluating eligibility (**see Extended Data Fig. 1**),
110 patterns that allowed to be fitted hyperbolic shapes appeared (**Fig. 3, d-f, & g-i**).

111 Considering the cause of these patterns, we found the matching between grouping the data by
112 hyperbolic patterns and grouping by data cut-off days (**Extended Data Fig. 7**). We calculated weighted

113 averages of age by grouping. In the earlier days group, non-severe was 46.5, severe was 57.7, and middle age
114 (45-64). In the late date group, non-severe was 40.9, and severe was 68.6, which were mature age (25-44) and
115 elderly (> 65), respectively.

116 Surprisingly, we found unrecognized patterns during the data review process in a figure reported by
117 Guo et al.³⁵, which showed a relationship between N-terminal pro-brain natriuretic peptide (NT-proBNP) and
118 Troponin T (TnT). There were three clusters of subgroup patterns, and each cluster could be fitted parabola
119 **(Fig. 4 a, b, Extended Data Fig. 8 & Extended Data Fig. 9)**.

120 The third subgroup pattern was similar to the pattern of ST-elevating myocardial infarction in the
121 figure report by Budnik et al³⁶. That study was a comparative study between Takotsubo cardiomyopathy (also
122 known as stress cardiomyopathy or broken heart syndrome) and ST-elevating myocardial infarction. This tiled
123 parabola appeared in another study on COVID-19 patients³⁷, and the pattern had already appeared in other
124 studies^{38,39} before the pandemic. However, those patterns were not recognised by each author.

125 Additionally, In the case of dropping points to the horizontal axis (troponin axis), the histogram on
126 the troponin axis results in bimodality. The above results matched the patterns reported by other studies
127 **(Extended Data Fig. 8)**^{37,40,41}.

128 Furthermore, by mounting the data of high-sensitivity C-Reactive protein (hsCRP) onto the third
129 subgroup and constructing a parabolic cylinder, we found a pattern that might further be subdivided into two
130 subgroups on the side surface of this parabolic cylinder **(Fig. 4, c, d, & Extended Data Fig. 10)**.

131

132 **Discussion**

133 Using pattern recognition of hyperbolic shape as a key to discoveries in exploratory data analysis,
134 we started research for traveller's Thrombosis and COVID-19, and as a result, our concept of the geometrical
135 viewpoint allowed us to discover many unrecognised patterns. Therefore, approaching data from geometry
136 and exploring data focusing on hyperbolic patterns can be a practical option for researchers.

137 In traveller's thrombosis, we obtained consistent results from two analyses (7.1 hours and 11.8 hours
138 vs 9.2 hours and 12.1 hours) (**Fig. 2, b, Extended Data Fig. 3**). The discrepancy between the value of 7.1
139 hours and 8.5 hours seems to be explained by the miscalculation found in the data review process (see
140 Methods). Although many researchers have led controversial discussions based on a single curve, our results
141 implied two S-curves. We hypothesised two high-risk periods and two types of high-risk groups, which may
142 have to be considered with the "factor V Leiden paradox"⁴² (**Supplementary discussion 3: two high-risk
143 periods and two types of high-risk groups?**).

144 Another noteworthy point is the cyclic patterns (wave) (**Fig. 2, c, d**) and the raw-risk period just
145 before 90 days in Kelman et al.²⁷ (**Extended Data Fig. 5**). In Cannegieter et al.²⁴, the cyclic pattern
146 disappeared around 90 days, consistent with that the high-risk period in oral contraceptive (OC) use was the
147 first three months (90 days)⁴². Also, the above raw-risk period explains extended-use type OC, which has a
148 planned drug withdrawal, such as 84 active days and seven placebo days⁴³⁻⁴⁵. In addition, the uptrend in the
149 data by Kelman et al.²⁷ could be explained by depot agent type OC administrated 90 days cycle⁴⁶. So, our
150 findings imply that the 28 days cycle OC is attributable to the cyclic pattern, and both cycle type and

151 extended-use type OC use is triggered by travel. An opposition may arise considering that both of relative risk
152 reported by Martinelli et al.²² and Cannegieter et al.²⁴ were low (**Fig. 2, b**), but it seems to be explained by
153 bias derived from using their partner as control (**Supplementary discussion 4: OC users and bias by their**
154 **partner**).

155 A halfway cycle (17.9 days) in Kelman et al.²⁸ was explained by a mixture of the 28 days OC cycle
156 and a type of HRT cycle (sequential type; daily estrogen dosing and 10–14 days progestogen)⁴⁶. Also, another
157 problem is that the wave in Cannegieter et al. was clear (thrombosis onset: March 1999-March 2000)²⁵.
158 However, the wave in Kelman et al. (1981-1999)²⁸ was not clear despite the exposures in Cannegieter et al.
159 (air travel, train, bus, and 48.5% car trip)²⁵ was more complex than Kelman et al. (only air travel)²⁸, was
160 answered by the history of HRT. In Kelman et al.²⁸, there might be both young women taking OC and
161 menopausal women receiving HRT, but only OC users might remain after the HERS study reported risk of
162 HRT (1998)³¹, which was assisted by the growth of thrombosis onset slowed at the HERS study³¹ (**Extended**
163 **Data Fig. 6**). Also, the above cars might be honeymoon cars. Although it was not decreasing, the result might
164 be caused by some woman's desire for joyful travel to Paris with HRT.

165 Our thought on pharmacoepidemiology in the real world, starting OC or HRT was triggered by
166 travel and decision making of HRT connected to travel, which means that well-planned usage based on risk
167 diversification may allow more safe use of OC and HRT.

168 In appreciation of our ideas to COVID-19, the dataset grouping by Matsushita et al.³² matched the
169 grouping by data cut-off dates (**Extended Data Fig. 7**), and age structure diverged from middle age to mature

170 and elderly, which was consistent with the hypothesis that COVID-19 spread from the seafood market.

171 Middle-aged people might go into the workforce for manual labour treating fish containers, mature people

172 might want to select IT jobs, and elderly people might stay in the house.

173 Interestingly, our analysis of the data by Guo et al.³⁴ showed three clusters of subgroups, and one of

174 those formed the tilted parabola. Also, the patterns matched the other studies (**Fig. 4 a, b, Extended Data Fig.**

175 **8 & Extended Data Fig. 9**)³⁶⁻⁴¹. Considering the study by Budnik et al.³⁶, those subgroups may have different

176 biological mechanisms.

177 Additionally, we found patterns on the side surface of this parabolic cylinder (**Fig. 4, c, d, &**

178 **Extended Data Fig. 10**). A paradoxical result on troponin was obtained just before the pandemic⁴⁸, and

179 Meisel et al. mentioned that the CRP to troponin ratio (CRP/troponin) could serve to differentiate between

180 myopericarditis and acute myocardial ischemia (AMI), although not the study on COVID-19 patients. In

181 COVID-19, Caro-Codón et al. reported interesting behaviour of CRP³⁵. Also, a meta-analysis by Lagunas-

182 Rangel reported that the lymphocyte-to-C-reactive protein ratio (LCR) level, which was not a simple

183 measurement value but a ratio, might be related to an inflammatory process⁴⁷.

184 The above studies might imply complex data structures in 2-dimensional and 3-dimensional scatter

185 plots consisting of biomarker values, and our findings may serve cardiac biomarkers' research field.

186 Supplementary, we explain the misuse of linear regression analysis in the study by Guo et al.³⁵

187 (**Supplementary discussion 5: misuse of linear regression analysis**).

188 Although many studies on visualization of meta-analysis have been conducted⁴⁸, our simple idea
189 (hyperbolic pattern) has not been proposed. As named “error”, researchers usually view an error bar
190 negatively. Also, in the wheel's history, an invention of carriages, which was achieved by arranging the
191 wheels in parallel, appeared in ancient times, but the idea of the bicycle, which was innovatively arranging
192 wheels vertically, had not been conceived before the 19th century^{49,50}. Those mental blocks might have made
193 it hard to imagine that vertical error bars provided information on a horizontal axis.

194 Evaluating our ideas, we discovered many oversights which were entirely beyond the initial scope.
195 Appearing overlapped hyperbolic patterns may show poor data review and analysis. Currently, pattern
196 recognition based on Artificial Intelligence (AI) detects cancer sites from images. Considering our discoveries
197 by an analogy that Newton's theory enabled the prediction of a planet's orbit, implementing our idea (a kind of
198 mathematical model or theory) in an AI system might assist another discovery of clinical issues.

328 **Methods**

329 **1. Numerical experiment**

330 Unavoidably, this study conducted a numerical experiment to determine what curve approximates an
331 edge of a confidence limit (**Fig. 1, c**).

332 Generally, a dose-response relationship often indicates an S-curve. Considering the distribution of a
333 population at thrombosis risk and the cumulative thrombosis onset, each of those is monomodal distribution
334 and the S-shaped curve, respectively. So, we decided to use the sigmoid function, which is generally used in
335 curve fitting to dose-response data, as the formula for the S-curve fitting.

336 Contrastively, the curve expressing the end of a confidence interval (confidence limit) is a sum of
337 the S-shaped curve and U-shaped curve because the width of the confidence interval narrows near the centre
338 of distribution due to many cases around the points. Similarly, the confidence interval widens at the
339 distribution edge due to the small number of cases (**see Fig. 1, d**).

340 Based on the above consideration, we selected the parabola as a candidate for the U-shaped curve
341 because this curve was mathematically easy to handle (just junior high school level mathematics). So, we
342 examined the validity of using parabola. However, mathematical proof of our conjecture was difficult because
343 normal distribution was continuous probability distribution. So, we used a kind of discrete probability
344 distribution, binomial distribution, to prove our conjecture experimentally because normal distribution could
345 be approximated by binominal distribution. This idea was thinking in reverse of the usual statistical technique.

346 To generate binomial distribution data, we used the "BINOM.DIST" function, which is a function
347 for calculating the probability of binomial distribution in a kind of spreadsheet software, Microsoft Excel[®]
348 (Microsoft Corporation, Redmond, Washington, US).

349

350 2. Equations for regression analysis

351 The equations for the S-shaped curve, the upper end of the confidence limit, and the lower end of the
352 confidence limit, those equations are the following (1), (2), and (3), respectively. Note that in the below
353 equations, the coefficient L is generally set as 1. So we used this equation under the condition as L=1 unless
354 there is some reason.

355

$$356 \quad y = \left\{ \frac{K_1}{1+e^{L(x-M)}} + K_2 \right\} \quad (1)$$

$$357 \quad y = \left\{ \frac{K_1}{1+e^{L(x-M)}} + K_2 \right\} + (ax^2 + bx + c) \quad (2)$$

$$358 \quad y = \left\{ \frac{K_1}{1+e^{L(x-M)}} + K_2 \right\} - (ax^2 + bx + c) \quad (3)$$

359

360 Also, a complete square of the quadratic function that represents the parabola is the following equation (4).

361

$$362 \quad ax^2 + bx + c = a \left(x + \frac{b}{2a} \right)^2 - \frac{b^2 - 4ac}{4a} \quad (4)$$

363

364 Besides, the point P is the apex of the parabola is the following (5).

365

366

$$P\left(-\frac{b}{2a}, -\frac{b^2-4ac}{4a}\right) \quad (5)$$

367

368 The following equations are the formula that expresses the outline of the distribution obtained by differential
369 calculation on the S-shaped curve (6).

370

371

$$\frac{dy}{dx} = -\frac{K_1 L e^{L(x-M)}}{\{e^{L(x-M)} + 1\}^2} \quad (6)$$

372

373 3. Analysis tools in this study

377

378

379

380

381

382

383

Reading values from the published figures were performed using the public domain software ImageJ in the public domain (<https://imagej.net/Welcome>). Regression analysis was performed using Python (Python Software Foundation, Delaware, USA <https://www.python.org/psf/records/incorporation/>). At this time, Python's functional modules NumPy (NumFOCUS sponsored open-source project, <https://numpy.org/>), Pandas (NumFOCUS sponsored open-source project, <https://pandas.pydata.org/>), SciPy (NumFOCUS sponsored open-source project, <https://www.scipy.org/>) and Matplotlib (NumFOCUS sponsored open-source project, <https://matplotlib.org/>) were also used. Additionally, a function as "Chart option" of Microsoft Excel[®], which was shown in the "Trendline Options" section contained in "Format Trendline," was used. In the case of symbolic formula manipulation was required, formula manipulation software wxMaxima (Project Maxima maintained by 27 volunteers, <https://maxima.sourceforge.io/>) was used.

384

385 **4. Analysis 1A (dataset: Chandra et al.)⁷**

386 1) Data review to validate eligibility for regression analysis

387 a. The process of data review in this analysis

388 As the first step, we performed data mapping. In the figure of meta-regression analysis reported by
389 Chandra et al.⁷, it was not described what the data points correspond to the four original papers (Martinelli et
390 al., 2003; Parkin et al., 2006; Cannegieter et al., 2006 and Kuipers et al., 2007)²³⁻²⁶. So, we measured the
391 positions of each point and compared them with the original descriptions in the papers. In the second step, we
392 performed a data review, which was an examination of the accuracy of cited values, and appropriately from
393 the viewpoint of biomedicine. Our re-calculation confirmed the odds ratio (OR), confidence interval of the
394 OR, and adjusted OR. In examining the values, we did not confirm Chandra et al.⁷ and the four authors²³⁻²⁶
395 because Chandra et al. described that each author did not respond to inquiry⁷. As a final step, we performed
396 regression analysis using the eligible data for using regression analysis.

397

398 b. Data review

399 The data review showed some problems in the research reported by Cannegieter et al. and Martinelli
400 et al.^{23,25}, and we excluded those data in the regression analysis. Also, there was a point to notice in the data
401 reported by Parkin et al.²⁴ (see **Extended Data Fig. 1**).

402 In confirming the accuracy of the values, there were no problems with the two studies (Kuipers et al.
403 and Cannegieter et al.)^{25,26}, but there were problems in the other two studies (**Martinelli et al. and Parkin et**
404 **al.**)^{23,24}.

405 In Martinelli et al.²³, the problem was gender imbalance and unadjusted OR. In addition, although
406 there were no explanations for the odds ratio described in the text cited by Chandra et al.⁷, the above OR was
407 presumed to be an unadjusted value, judging from the context. Comprehensively, judging from both
408 calculation results and the original article, the odds ratio cited by Chandra et al.⁷ was strongly suspected of
409 being an unadjusted value.

410 In Parkin et al.²⁴, there was a discrepancy between the OR and the described OR calculated by us.
411 Also, it was suspected that cells in the cross table were mistaken (*e.g.*, in the table of Fig. 1a, the cell for
412 control and the cell for total were mistaken). However, the error bar's length was relatively small since the
413 total number of cases was notably smaller than other studies. So, qualitatively, it could only be used to group
414 data to find hyperbolic patterns.

415 In confirming from the viewpoint of the biomedicine side, there were no problems with two studies
416 (Kuipers et al. and Parkin et al.)^{24,26}, but there were problems in the other two studies (**Martinelli et al. and**
417 **Cannegieter et al.**)^{23,25}. In Martinelli et al.²³, judging from the subtitle, "interaction with thrombophilia and
418 oral contraceptives," oral contraceptive (OC) bias was suspected. Initially, the study aimed to evaluate the
419 interaction between OC use and travel. Considering the above, the OR had to be considered a value that
420 contained a strong bias (**see also Supplementary discussion 4: OC users and bias by their partner**). In

421 Cannegieter et al.²⁵, the data contained car travel, and the other studies contained only air travel. So exposure
422 factors were different, and there was a problem from the viewpoint of comparability (e.g., air pressure,
423 dehydration, and time difference). Also, Chandra et al.⁷ showed two types of analysis results, including
424 Cannegieter et al.²⁵ and not. Besides, the cyclic pattern could be explained by OC use was observed (see Fig.
425 **2, c & d**). Also, Cannegieter et al.²⁵ did not adjust the OR by sex and OC use. So, it was strongly suspected
426 that there was a strong bias derived from the different types of exposure factors and OC.

427 Judging from the above two types of data reviews, we excluded the data reported by two studies
428 (**Martinelli et al. and Parkin et al.**)^{23,24}. In the data reported by Kuipers et al.²⁶, there was no problem. The
429 data reported by Parkin et al.²⁴ seemed to be used only for the purpose described above.

430 Interestingly, in four studies used in meta-regression analysis by Chandra et al.⁷, all the first authors'
431 names seem to be women's names ("Suzanne" Cannegieter²⁵, "Saskia" Kuipers²⁶, "Ida" Martinelli²³, "Lianne"
432 Parkin²⁴).

433

434 2) Regression Analysis

435 For the data judged as eligible, hyperbolic patterns were visually searched, and each data point was
436 grouped into two groups. Then, a non-linear regression analysis using the formulas above was performed. In
437 the fitting of the U-shaped curve, since there were many unknown coefficients for the number of data (there
438 are seven unknowns, K_1 , K_2 , M , a , b , and c . in the equations (2) and (3)), the S-curve was fitted first, and the

439 remaining unknown coefficients (a, b, c) were fitted to the residuals of the S-curve fitting (see equation (2)
440 and (3)).

441

442 3) Additional analysis

443 As described above, the cyclic pattern in the data reported by Cannegieter et al.²⁵ was observed, and
444 we performed additional analysis. To conduct an appropriate non-linear regression analysis, we made an
445 equation by combining two types of equations. The exponential decay equation was usually used to express
446 radioactive decay in physics and clearance in medicine. The other was a trigonometric function (sine function)
447 to express waveforms. The equation is shown in as below equation (7). Also, this scientific model (model
448 formula) was used to estimate the ratio of patients by integral calculation.

449

$$450 \quad y = N_1 e^{-\lambda_1(t-b)} + N_2 e^{-\lambda_2(t-b)} \text{Asin}\{B(t-b)\} \quad (7)$$

451

452 The data reported as a bar graph was weekly data (see Fig. 2, c and Extended Data Fig. 2). So, the
453 week was converted into the number of days before the analysis, such as; the day getting off the vehicle was
454 set as days 0, the first week was set as days 4, the second week was set as days 4 + 7, and the third week was
455 set as days 4 + 7 × two, and the Nth week was set as days 4 + 7 × N.

456 Supplementary, according to the original description by Cannegieter et al.²⁵, 68 patients developed
457 thrombosis in the first week, and "233" patients developed thrombosis within eight weeks after travelling.

458 However, there was a slight discrepancy in the values read from the bar graph. The value in our measurement
459 within eight weeks after travelling was "234", but the effect of only one patient was allowed to be regarded as
460 small (the description of 68 patients was the same.).

461 Cannegieter et al. described the number of patients who travelled with their partners to evaluate the
462 effect of OC (Cannegieter et al., PLoS Med. 2006 Aug;3(8):e307., Table 2)²⁵. We found some mismatches for
463 the number of patients in the table, and the overall discrepancy was only one person by offset, and
464 Cannegieter et al. described that there were derived from missing value²⁵. The mismatch between our
465 measurement and description might be related to the described explanation.

466

467 **5. Analysis 1B (dataset: Philbrick et al.)⁴**

468 1) Dataset search and data review

469 a. Dataset search

470 To validate the result of analysis 1A, we searched another dataset from meta-analysis or systematic
471 review on the traveller's thrombosis. To conduct this search, we used PubMed[®] setting the following search
472 keywords: "economy class syndrome [Title]" OR "traveler's [Title] AND thrombosis [Title]" OR "traveler's
473 [Title] AND thromboembolism [Title]" OR "flight [Title] AND thrombosis [Title]" OR "flight [Title] AND
474 thromboembolism [Title]" OR "flight-related [Title] AND thrombosis [Title]" OR "flight-related [Title] AND
475 thromboembolism [Title]" OR "travel [Title] AND thrombosis [Title]" OR "travel [Title] AND

476 thromboembolism [Title]" OR "travel-related [Title] AND thrombosis [Title]" OR "travel-related [Title] AND
477 thromboembolism [Title]" (Filters: Meta-Analysis, Systematic Review).

478 As a result, we obtained the eight articles (da Silva LF et al. *J Vasc Bras.* 2021 10;20:e20200164;
479 Benhaberou-Brun *Perspect Infirm.* 2010 7(3):16-7; Chandra et al. *Ann Intern Med.* 2009 151(3):180-90;
480 Kuipers et al. *J Intern Med.* 2007 262(6):615-34; Philbrick et al. *J Gen Intern Med.* 2007 22(1):107-14; Hsieh
481 et al. *J Adv Nurs.* 2005 51(1):83-98; Ansari et al. *J Travel Med.* 2005;12(3):142-54; Adi et al. *BMC*
482 *Cardiovasc Disord.* 2004 19;4:7).

483 Subsequently, we selected articles containing available abstracts on PubMed® online, confirming the
484 contents. As a candidate for our analysis, we selected a systematic review reported by Philbrick et al.⁴. The
485 study was taken up by the ACP Journal Club of the American College of Physicians⁵ and another journal
486 club¹⁰. So, it seemed to be a highly reputed study. Therefore, we regarded that the dataset contained in the
487 research was suitable for validation.

488 Also, the research contained two lists of tables, one of which was a cohort studies dataset, and the
489 other was the case-control studies. However, the case-control studies had many different exposure factors. So,
490 we decided to use only the cohort studies dataset.

491

492 b. Data review

493 In the data review process, we reviewed the table containing ten cohort studies^{27,28,51-58} and found
494 seven eligible cohort studies^{27,51,54-58} for regression analysis. In Gajic et al. and Kelman et al., the only

495 distances were described^{28,52}, and Hughes et al. reported duration data for not per one flight (e.g., mean 39.4
496 h)⁵³, so time data for regression analysis was unavailable.

497 Additionally, although Philbrick et al. described that incidence per million was 0.5 in table 2 of their
498 article⁴, the number was incorrect because it was based on only 1998. In the original description, Clérel &
499 Caillard mentioned that "According to the number of the passengers landing in the Aeroports de Paris, the
500 incidence during 1998 is 0.5 per million passengers"²⁷.

501

502 2) Regression Analysis

503 For the seven studies, data stratified by Pulmonary Embolism (PE) and Deep Vein Thrombosis
504 (DVT), regression analysis was performed using an S-shaped curve formula (see equation (1)). In the case of
505 curve-fitting on DVT data, we cancelled the setting of coefficient L=1 to increase the degree of freedom of the
506 S-curve (**Extended Data Fig. 3, b**). To show the error bar in the figure (**Extended Data Fig. 3**), we did not
507 use the values of confidence limits described in the report by Philbrick et al.⁴, but values were re-calculated
508 from the number of cases using Wilson's method because data review result described above showed the error
509 of values at the citation.

510 In the seven studies, not OR or relative risk (RR), only the data indicating the incidence rate of
511 thrombosis was available. So, the hyperbolic pattern did not appear in the figure theoretically, and we
512 performed only the S-shaped curve fitting. This mechanism is explanted from the following calculation on a
513 confidence interval of a ratio.

514 The formula for a 95% confidence limit of a ratio using binomial approximation is expressed by the
515 following formula: P is a ratio, and N is the number of trials.

516

$$517 \quad P - 1.96 \frac{\sqrt{P(1-P)}}{\sqrt{N}} \leq P \leq P + 1.96 \frac{\sqrt{P(1-P)}}{\sqrt{N}} \quad (8)$$

518

519 In the above equation, the fraction's numerator is not a constant value and does not depend on only the N,
520 which is associated with a data point's position in a population (see Fig. 1).

521 In this regression analysis, converting time categories to time points was necessary, so we performed
522 this in three directions. The first one was taking the midpoint if the category was not the end of a category
523 sequence (e.g., 10-15 h could be converted to 12.5 h). The second one was taking the midpoint between the
524 time point of 0 and the lower limit of the category if the category was the lower end of a category sequence
525 (e.g., <3 h could be converted to 1.5 h). The third one was taking the sum of the value of the upper limit and
526 the value of the midpoint between the time point of 0 and the lower limit of the category sequence if the
527 category was the upper side of a category sequence (e.g., > 12 h could be converted to 12 h + 1.5 h =13.5 h).
528 Details of conversions are shown below (the original time category is shown in brackets).

529 Belcaro et al. [10-15 h]: 12.5 h (Belcaro, G. et al., *Angiology*. 2001;52(6):369-74.)⁵¹; Clérel et al.
530 [12.7 h]: 12.7 h (Clérel, M., & Caillard, G., *Bull Acad Natl Med*. 1999;183(5):985-97.)²⁷; Jacobson et al. [11
531 h]: 11 h; Lapostolle et al. [<3 h, 3-6 h, 6-9 h, 9-12 h,> 12 h]: 1.5 h, 4.5 h, 7.5 h, 10.5 h, 13.5 h (12 + 1.5 = 13.5
532 h) (Jacobson, B.F. et al., *S Afr Med J*. 2003;93(7):522-8.)⁵⁴; Pérez-Rodríguez et al. [<6 h, 6-8 h,> 8 h]: 3 h, 7

533 h, 11 h (8 + 3 = 11 h) (Pérez-Rodríguez, E. et al., *Arch Intern Med.* 2003;163(22):2766-70.)⁵⁶; Schwarz et al.
534 2002 [> 8 h]: 12 h (midpoint of 0-8 h is 4 h and 8 + 4 = 12 hours) (Schwarz, T. et al., *Blood Coagul*
535 *Fibrinolysis.* 2002;13(8):755-7.)⁵⁷; Schwarz et al. 2003 [> 8 h]: 12 h (midpoint of 0-8 h is 4 h and 8 + 4 = 12
536 hours) (Schwarz, T. et al., *Arch Intern Med.* 2003 2003;163(22):2759-64.)⁵⁸.

537

538 3) Additional analysis

539 a. Regression analysis (data: Kelman et al.²⁸)

540 In the review process, a cyclic pattern was observed. So, we worked on regression analysis.

541 Considering that onset of thrombosis tends to increase again, an equation upward-sloping curve was added to

542 equation (7). The equation is the following (9).

543

$$544 \quad y = N_1 e^{-\lambda_1(t-b)} + N_2 e^{-\lambda_2(t-b)} \text{Asin}\{B(t-b)\} + (ax^2 + bx + c) \quad (9)$$

545

546 b. Analysis by using correlogram (data: Clérel & Caillard²⁷)

547 We considered using the "correlogram" in this study because it was more practical than observing

548 the original data's fluctuation. Periodic fluctuation patterns may be unclear when looking at the original data

549 alone, but potential patterns can be obtained using a correlogram, a data visualization method for analyzing

550 time-series data. Also, as the correlation coefficient plotted on the correlogram, we decided to use Spearman's

551 rank correlation coefficient instead of Pearson's product-moment correlation coefficient, which is easily

552 affected by outliers. Also, we performed a non-linear regression analysis using a mathematical formula (10)
553 that includes two sine functions.

554

$$555 \quad y = n_1 \sin\{a_1(x - b_1)\} + n_2 \sin\{a_2(x - b_2)\} \quad (10)$$

556

557 In correlogram creation, firstly, a combination of data (data X1, data X1) was created by arranging
558 the original time series data (data X1) and a new combination (data X1, data X1') was created by shifting one
559 of them. Secondary, the correlation coefficient (also called the auto-correlation coefficient) between the
560 original time-series data (data X1) and the sifted time-series data (data X1'), except at the ends of two types of
561 time-series data where some correspondence could not be formed. By repeating shifting the time string data
562 and calculating the correlation coefficient, the locus of the correlation coefficient becomes the shape of waves.
563 Firstly (original waves of time strings are overlapped), the correlation coefficient is 1, and the value of the
564 correlation coefficient gradually decreases as the distance of the overlap increases. Finally (the wave is
565 inverted), the correlation coefficient is -1.

566 In this study, since the risk of developing thrombosis is expected to increase as travel time increases
567 by cumulative exposure to environmental risk factors, it was necessary to investigate whether the fluctuations
568 in the number of patients really reflect the periodicity by confirming the fluctuation of the percentage of onset
569 patients to the total number of passengers to examine whether the fluctuation reflects the increase or decrease
570 in the number of passengers. However, this confirmation could not be made because data on the total number

571 of passengers was not available. So, we focused on a method that suppressed the influence of the height of the
572 wave and evaluated only curved shapes. Therefore, we decided to draw a correlogram that reduced wave
573 height by the property of the correlation coefficient, which fluctuates only between -1 and 1.

574 However, Pearson's product-moment correlation coefficient has a weakness: it is easily affected by
575 outliers. Also, as the progress of shifting the one side of the data string against the original data, their
576 correspondence decreases. In other words, the number of data that can be used to calculate the correlation
577 coefficient gradually decreases. This problem may cause considerable variation between the calculated
578 correlation coefficients. Also, the thrombosis onset was recorded in 1-hour increments, and the length of the
579 data was limited to 24 hours (24 data points). Therefore, instead of Pearson's product-moment correlation
580 coefficient, we decided to create a correlogram using Spearman's rank correlation coefficient.

581

582 **6. Analysis 2 (dataset: COVID-19)³³**

583 1) Dataset search and data review

584 c. Dataset search

585 To apply our idea to COVID-19 problems, one of the authors (KK) searched hyperbolic patterns
586 using a search service Google (<https://www.google.com/>) provided by Google Inc., which allows displaying
587 search results as "images." The search keyword was "COVID-19 AND Meta-analysis". In the case of
588 displaying bubble charts instead of the error bars, the size of the bubble chart (inversely proportional to the
589 length of the error bars) was converted in mind. Consequently, we selected a suspicious study reported by

590 Matsushita et al. (Matsushita, K. et al., *Glob Heart*. 2020;15(1):64.)³³ that included eight research papers in
591 Figure 5⁵⁹⁻⁶⁶.

592

593 d. Data review

594 As in the case of Analysis 1, we reviewed to evaluate numerical accuracy and appropriateness from
595 the viewpoints of biomedicine. Since Matsushita et al.³³ originally made web Figure 5 and excluded 17
596 studies^{35,67-82} from avoiding duplication of studies in Wuhan city in the making of Figure 5, we inspected both
597 of studies in Figure 5 (8 studies) and only in web Figure 5 (17 studies).

598 Based on the results shown below, considering the issue of comparability, we excluded the data
599 reported by Yuan et al.⁶⁵ and Wang L. et al⁶³. Also, we re-calculated age difference using data reported by
600 Guan et al. ⁶¹ (**see Extended Data Fig. 1**).

601 As a side note, the numbers assigned to each point in figure 3 were the same numbers described in
602 the original figure by Matsushita et al.³³, and the correspondence relationship is the following (**Fig. 3**): **No.2**:
603 Cao et al. (Cao, J. et al., *Intensive Care Med*. 2020;46(5):851-853.)⁵⁹, **No.7**: Deng et al. (Deng, Y. et al., *Chin*
604 *Med J (Engl)*. 2020;133(11):1261-1267.)⁶⁰, **No.8**: Guan et al. (Guan, W.J. et al., *N Engl J Med*.
605 2020;382(18):1708-1720.)⁶¹, **No.19**: Wang D. et al. (Wang, D. et al., *JAMA*. 2020;323(11):1061-1069.)⁶²,
606 **No.20**: Wang L. et al. (Wang, L. et al., *J Infect*. 2020;80(6):639-645.)⁶³, **No.21**: Wu et al. (Wu, C. et al., *JAMA*
607 *Intern Med*. 2020;180(7):934-943.)⁶⁴, **No.23**: Yuan et al. (Yuan, M. et al., *PLoS One*. 2020;15(3):e0230548)⁶⁵,
608 **No.25**: Zhou et al. (Zhou, F. et al., *Lancet*. 2020;395(10229):1054-1062.)⁶⁶.

609

610 (i) No.8 Guan et al. (Guan, W.J. et al., *N Engl J Med.* 2020;382(18):1708-1720.)⁶¹

611 We found a matter of consideration in the data reported by Guan et al.⁶¹. Initially, features of that
612 data differed from the other studies, which contained only cases reported from Wuhan city. In contrast, the
613 data reported by Guan et al.⁶¹ contained cases outside of Wuhan city. Also, regarding the situation of the early
614 pandemic, there were concerns about the presence of patients who could not take appropriate medication,
615 especially in non-urban areas. Also, Matsushita et al.³³ did not use the data divided into the severe and non-
616 severe groups by Guan et al.⁶¹ but used the data divided into yes and no by Guan et al.⁶¹ using "Presence of
617 Primary Composite End Point", which means entry to the intensive care unit (ICU), use of mechanical
618 ventilation, or death.

619 Since Cao et al. (Wuhan University Zhongnan Hospital in Wuhan; affiliation of Dr Jianlei Cao:
620 Department of Cardiology)⁵⁹ and Wang et al. (Zhongnan Hospital of Wuhan University in Wuhan; affiliation
621 of Dawei Wang, MD: Department of Critical Care Medicine)⁶² also used ICU admission as a criterion for
622 severe or non-severe, we examined the rate of severely ill patients and resulted in 21.4% (18/84) and 35.3%
623 (36/102), respectively. However, in the case of using the "Presence of Primary Composite End Point", the
624 percentage was only 6.5% (67/1032). Whereas, in the original categorisation by Guan et al.⁶¹, the percentage
625 was 18.7% (173/926). Therefore, we prioritised the original classification of severe or non-severe by Guan et
626 al.⁶¹.

627

628 (ii) No. 9 Guo et al. (Guo et al. *JAMA Cardiol.* 2020;5(7):811- 818)³⁵ (only in eFigure5)

629 We read this paper carefully, a report from Wuhan city published in March 2020. Although this
630 document may significantly influence the studies on COVID-19 (according to the JAMA Cardiology website,
631 the article was cited more than 1,500 as of 20th September 2021), we found that misuse of linear regression
632 analysis in Guo et al. on a figure (see Extended Data Fig. 8 & **Supplementary discussion 5: misuse of linear**
633 **regression analysis**)³⁵.

634 Additionally, three subgroup patterns appeared in a figure reported by Guo et al., although they did
635 not mention it. Precautionary, we considered whether the subgroups in the Guo et al.³⁵ affected the meta-
636 analysis on the web Figure 5. The data in other studies allowed to be expected to have the same subgroups
637 because the patient data described by Guo et al.⁷¹ and other studies were reported from China (most of them
638 were in Wuhan City).

639

640 (iii) No. 20 Wang L. et al. (Wang, D. et al., *JAMA.* 2020;323(11):1061-1069.)⁶³

641 In confirming from the viewpoint of the biomedicine side, it was found that a significant matter of
642 consideration on eligibility, patient population reported by Wang L. et al. was limited to over age 60⁶³. The
643 title was "Coronavirus disease 2019 in elderly patients: Characteristics and prognostic factors based on 4-
644 week follow-up", and Matsushita et al.³³ had to pay attention to the word "elderly".

645

646 (iv) No.23 Yuan M. et al. (Yuan M. et al., *PLoS One*. 2020;15(3):e0230548.)⁶⁵

647 In confirming the accuracy of values, we found a mixture of values derived from different
648 calculation types in Figure 5: Odds Ratio (OR), hazard ratio, and a value derived from the imputation of 0.5
649 for the zero cells in the cross table. The zero cells appeared in the study reported by Yuan et al⁶⁵. Yuan M. et
650 al. studied 27 patients who confirmed novel coronavirus infected pneumonia (NCIP) during the early phase of
651 the pandemic to evaluate radiologic characteristics⁶⁵. In other words, the difficulty of patient enrollment might
652 cause a small sample size, which seemed to be a concern from the viewpoint of comparability (c.f., Guan W.
653 et al., n=1099⁶¹; Zhou F. et al., n=191⁶⁶; Wang D. et al., n=138⁶²; Wu C. et al. n=201⁶⁴; Cao J. et al., n=102⁵⁹;
654 Deng Y. et al., n=225⁶⁰).

655

656 (v) The term "Cardiovascular disease (CVD)."

657 There was an inconsistency in the studies on "Cardiovascular disease (CVD)." For example, vascular
658 diseases such as arrhythmia and arteriosclerosis are also classified as CVD, but in the studies reported by
659 Guan et al.⁶¹ and Zhou et al.⁶⁶, the term "Coronary heart disease" was used. Also, "Cardiac disease" was used
660 by Yuan et al.⁶⁵, "Heart disease" was used by Deng et al.⁶⁰, and "Cardiovascular disease" was used by Wang L
661 et al⁶³.

662

663 2) Regression analysis

664 Considering the problem of comparability, we re-calculated OR and visually grouped it into two
665 hyperbolic patterns. In the case of S-shaped curve fitting, since there were many unknown coefficients for the
666 number of data (3 unknown coefficients of K_1 , K_2 , and M), the regression analysis was performed after setting
667 the zero point value. In the fitting of upper and lower curves, since there were many unknown coefficients
668 (K_1 , K_2 , M , a , b , c), we firstly obtained the coefficient of M (see equation (1)) by the curve fitting of the S-
669 shaped curve, and then performed curve fitting of parabolas. After substituting M for x value of apex in
670 equation (4) (see equations (4) & (5)), regression analysis was performed on the data in the middle row of
671 Figure 3 (**Fig. 3, d-f**). Finally, the S-shaped curve and the parabola were merged (**Fig. 3, g-i**).

672

673 3) Calculation of weighted average

674 In earlier days group, the median age and the number of cases are tabulated by severe and non-
675 severe cases as follows. Guan W. et al. (severe $n=173$ [age: 52] vs non-severe $n=926$ [age: 45])⁶¹, Zhou F. et
676 al. (non-survival $n=54$ [age: 69] vs survival $n=137$ [age: 52])⁶⁶, Wang D. et al. (ICU $n=36$ [age: 66] vs non-
677 ICU $n=102$ [age: 51])⁶², Wu C. et al. (ARDS $n=84$ [age: 58.5] vs non-ARDS $n=117$ [age: 48])⁶⁴, and whole of
678 earlier days group (severe $n = 347$ vs non-severe $n = 1282$).

679 The weighted average of severe and non-severe in the earlier days group was calculated from these
680 values by the following formulas. In the earlier days group, the weighted average of severe and non-severe
681 were 57.7 and 46.5, respectively.

682

683
$$\text{Number of patients in earlier days group (severe)} = 173 + 54 + 36 + 84 = \mathbf{347}$$

684
$$\text{Weighted mean of earlier days group (severe)} = \frac{173}{347} \times 52 + \frac{54}{347} \times 69 + \frac{36}{347} \times 66 + \frac{84}{347} \times 58.5$$

685
$$\cong 57.7$$

686

687
$$\text{Number of patients in earlier days group (non - severe)} = 926 + 137 + 102 + 117 = \mathbf{1282}$$

688
$$\text{Weighted mean of earlier days group (non - severe)}$$

689
$$= \frac{926}{1282} \times 45 + \frac{137}{1282} \times 52 + \frac{102}{1282} \times 51 + \frac{117}{1282} \times 48 \cong 46.5$$

690

691 In later days group, the median age and the number of cases are tabulated by severe and non-severe

692 cases as follows. Cao J. et al. (ICU n=18 [age: 66] vs non-ICU n=84 [age: 31])⁵⁹, Deng Y. et al. (Death n=109

693 [age: 69] vs survival n=116 [age: 48])⁶⁰, and whole of later days group (severe n = 127 vs non-severe n =

694 200).

695 The weighted average of severe and non-severe in the late date group was calculated from these

696 values by the following formulas. In the late date group, the weighted average of severe and non-severe were

697 68.6 years and 40.9, respectively.

698

699
$$\text{Number of patients in late date group (severe)} = 18 + 109 = \mathbf{127}$$

700
$$\text{Weighted mean of late date group (severe)} = \frac{18}{127} \times 66 + \frac{109}{127} \times 69 \cong 68.6$$

701
$$\text{Number of patients in late date group (non - severe)} = 84 + 116 = \mathbf{200}$$

702
$$\text{Weighted mean of late date group (non - severe)} = \frac{84}{200} \times 31 + \frac{116}{200} \times 48 \cong 40.9$$

703

704 4) Additional analysis: Regression analysis on the parabolic cylinder

705 One of the authors (KK) found a way to fit an appropriate curve to the data reported by Guo et al.,
706 performing trial and error with his mathematical intuition (**Fig. 4**). Firstly, he calculated the centre of gravity
707 of the data by each subgroup cluster (centre of gravity: the average of the values on the horizontal axis x and
708 the average of the values on the vertical axis y). Second, he obtained equations of three straight lines passing
709 through the origin and centres of gravity. Thirdly, he obtained the equation of a straight line passing through
710 each centre of gravity and intersecting the straight lines obtained above. Fourthly, he re-set new origin as each
711 centre of gravity and regarded the above two crossed lines as a small cartesian coordinate system. Finally, he
712 applied parabola fitting with Excel[®] in each new cartesian coordinate system. In this curve fitting, he used the
713 data of distance between each data point and the straight line obtained secondary, and the data of distance
714 between each data point and the straight line obtained firstly (see "distance from a point to a line" in a high
715 school textbook).

716

717 5) Making example data

718 To explain the misuse of linear regression analysis in Guo et al.³⁵, we made the following data to
719 show the example. It allows being used in R by copying and pasting the following.

720

721 Value_X<-

722 c(0.04,0.08,0.12,0.16,0.2,0.24,0.28,0.32,0.36,0.4,0.44,0.48,0.52,0.56,0.6,0.64,0.68,0.72,0.76,0.8,0

738

739 **7. Statement of our intention for data review results**

740 To clarify our stance, we mention this statement of intention for results. In this article, we pointed
741 out many overlooking and errors. However, we have no intention to attack previous works because our
742 analysis results owing to their original works, including original research articles, reported valuable data and
743 articles of meta-analysis synthesised valuable datasets. Since just a scientist had better reconfirm the previous
744 studies with no preconception with being grateful to the researchers of those studies, we carefully reviewed
745 the data reported by previous studies. We highly respect previous works, which have the intention to solve
746 medical issues, although some articles contained technical errors.

884 same method as Chandra et al. *Ann Intern Med.* 2009; 151(3):180-190. Figure 3⁷. We added information from

885 original studies and our hypothesis to the previously published form, such as latent distribution. The original

886 figure has been shown on the American College of Physicians website, which links to PubMed[®]

887 (<https://pubmed.ncbi.nlm.nih.gov/19581633/>). From Chandra D, Parisini E, Mozaffarian D. Meta-analysis:

888 travel and risk for venous thromboembolism. *Ann Intern Med.* 2009 Aug 4;151(3):180-90. doi: 10.7326/0003-

889 4819-151-3-200908040-00129. Epub 2009 Jul 6. © 2009 American College of Physicians. Adapted with

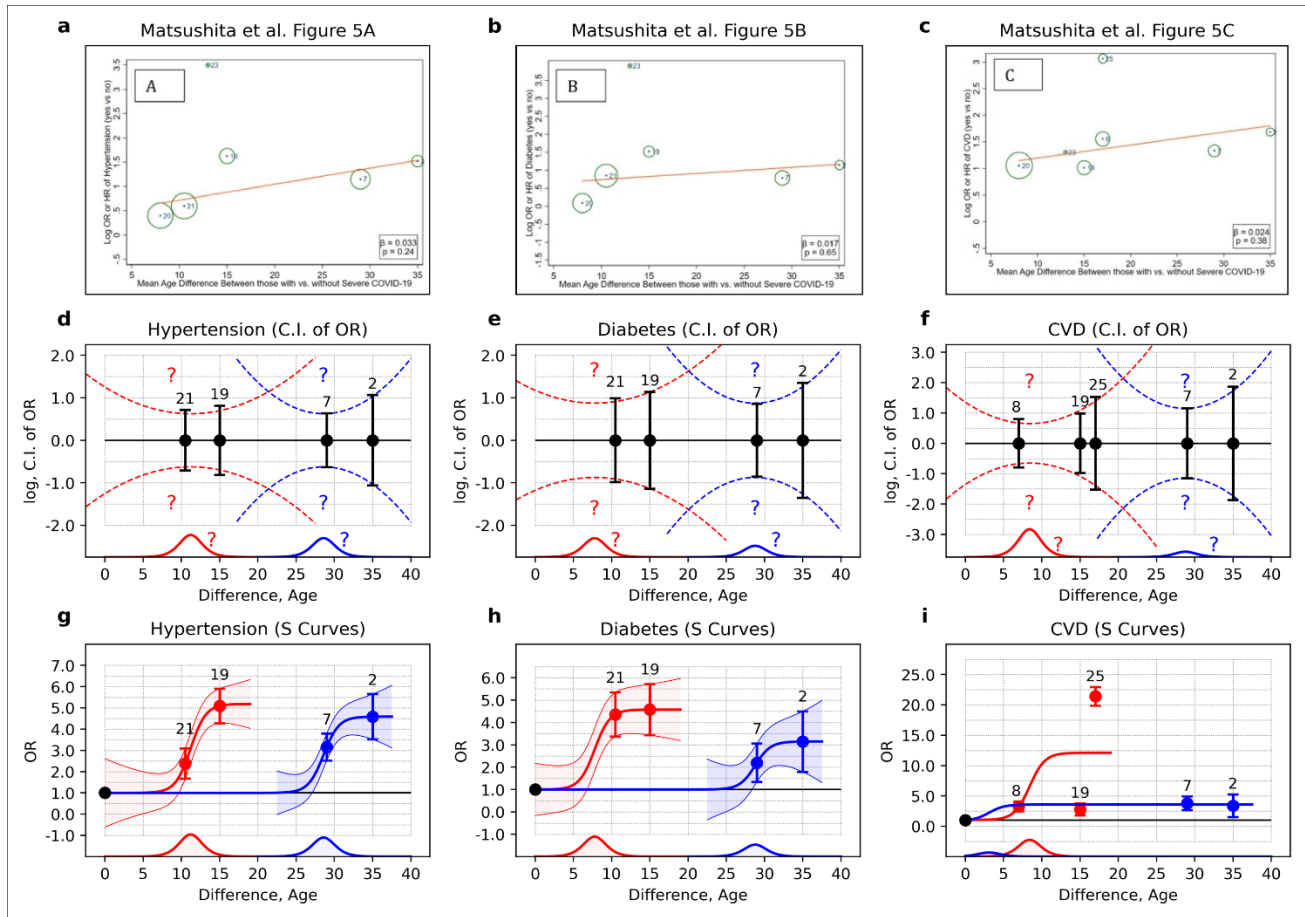

890 permission. **b**, grouping the data and hyperbolic shape fitting. **c**, Onsets of thrombosis after travel reported by
891 Cannegieter et al.²⁵. This figure was re-used and re-drawn from Cannegieter et al. Travel-related venous
892 thrombosis: results from a large population-based case-control study (MEGA study). *PLoS Med.* 2006;
893 3(8):e307. Figure 1. [https://www.ncbi.nlm.nih.gov/labs/pmc/articles/PMC1551914/figure/pmed-0030307-](https://www.ncbi.nlm.nih.gov/labs/pmc/articles/PMC1551914/figure/pmed-0030307-g001/)
894 [g001/](https://www.ncbi.nlm.nih.gov/labs/pmc/articles/PMC1551914/figure/pmed-0030307-g001/) Copyright © 2006 Cannegieter et al. Creative Commons Attribution License. In 2006, the Creative
895 Commons Attribution 2.0 Generic, License was available. <https://creativecommons.org/licenses/by/2.0/> **d**,
896 Applying the damped wave function to the data shown in panel c. We decided that the data from Martinelli et
897 al.²³ and Cannegieter et al.²⁵ should be excluded, and the odds ratio from Parkin et al.²⁴ may decrease (see
898 Methods). At 2 hours point, Chandra et al.⁷ did not use available data (panel a). On the original regression
899 line, Chandra et al.⁷ might conduct a meta-regression analysis reversing the front head and the front side of the
900 cross-tabulation. Comparing panels c and d helps us understand that using a three-dimensional graph disrupts
901 our recognition.

902

903

904

905 **Fig. 3**

906

907 **Fig. 3 | Hyperbolic shapes found in the figure reported by Matsushita et al³³. a, A figure shows the**

908 relationship between the severe and non-severe groups reported by Matsushita et al.³³, which shows age

909 difference on the horizontal axis and odds ratio (OR) or hazard ratio of hypertension on the vertical axis. To

910 evaluate potential confounding for relative risk by age, Matsushita et al. conducted meta-regression analyses

911 based on the assumption that there was the possibility of confounding by age in the case that the study with a

912 larger age difference has a higher relative risk³³. **b, Diabetes. c, Cardiovascular disease (CVD). d-f,**

913 Comparisons of error bars, which show 95% confidence interval (C.I.) s. It corresponds to the upper figure. **g-**

914 i, Hyperbolic patterns were fitted to the OR and the 95% confidence limit of the OR. In the panel i, a
915 hyperbolic shape could not be fitted due to the considerable data variation, likely due to the inconsistency of
916 the term "CVD" (see Methods). The numbers marked to each point are the same as the numbers shown in the
917 original figure. The sources of each data are shown in Methods. This figure was re-used from Matsushita et al.

938

939

940 **Extended data figures & figure legends**

941 **Extended Data Fig. 1**

942

943

944 **Extended Data Fig. 1 | Overall framework of this study.** We applied our concept to traveller's thrombosis

945 and COVID-19. These were similar in research history (see Supplementary discussion 1: history of traveller's

946 thrombosis & Supplementary discussion 2: research situations of COVID-19 related thrombosis). In the case

947 of traveller's thrombosis, we analysed a dataset collected by Chandra et al. and Philbrick et al.^{4,7}. In the case of

948 COVID-19, we analysed a dataset collected by Matsushita et al.⁷. Flow charts show data accept or reject flows.

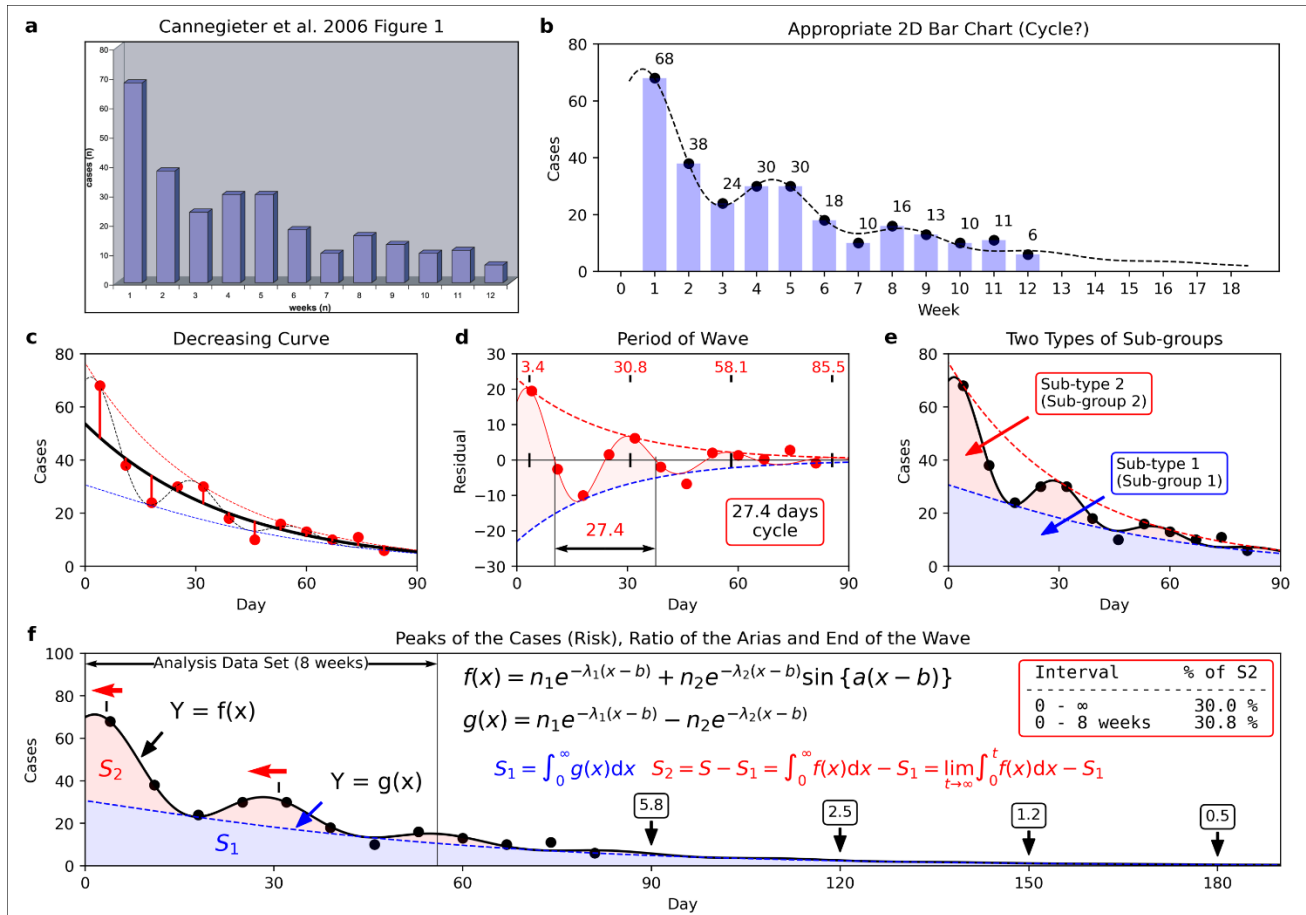

949 Since duplicating data, Matsushita et al. selected only eight studies data (25 studies included in initial web Figure

950 5)³³.

951

952

953 **Extended Data Fig. 2**

954

955 **Extended Data Fig. 2 | Unrecognised cyclic pattern of thrombosis onset after travel²⁵. a, A bar graph**

956 showing the relationship between weeks after travel and the number of thrombosis onset in a figure reported

957 by Cannegieter et al²⁵. **b, Re-expressing as a two-dimensional bar graph avoiding the three-dimensional**

958 representation. **c, Applying a damped wave by non-linear regression analysis. d, Extraction of damped wave**

959 part by subtracting the monotonic decrease function. **e, Dividing into 2 sub-group areas by the envelopes of**

960 the damped wave that touch the lower parts of the wave. **f, Enlarged and added explanation of the ratio of the**

961 area. Cannegieter et al.²⁵ used the data up to week eight, and the ratio of subgroup 2 to the total number of

962 patients (ratio of S_2 to the area of $S_1 + S_2$) was 30.0%. In the integration for the infinite interval, it was 30.8%.

963 Peak shifts of the wave (peak position of the wave shifted from the original to the other) appeared when

964 comparing panels d and f due to putting by regression curve located in the centre. Panel a was re-used from

965 Cannegieter et al. *PLoS Med.* 2006; 3(8):e307. Figure 1.

966 <https://www.ncbi.nlm.nih.gov/labs/pmc/articles/PMC1551914/figure/pmed-0030307-g001/>

970

971

972 **Extended Data Fig. 3**

973

974 **Extended Data Fig. 3 | Curve fitting to the dataset reported by Philbrick et al⁴.** a, data stratification by

975 Pulmonary Embolism (PE) and Deep Vein Thrombosis (DVT). b, Application of S-shaped curve by

976 regression analysis to the stratified data. The value in the bracket (panel b) is the point of time converted from

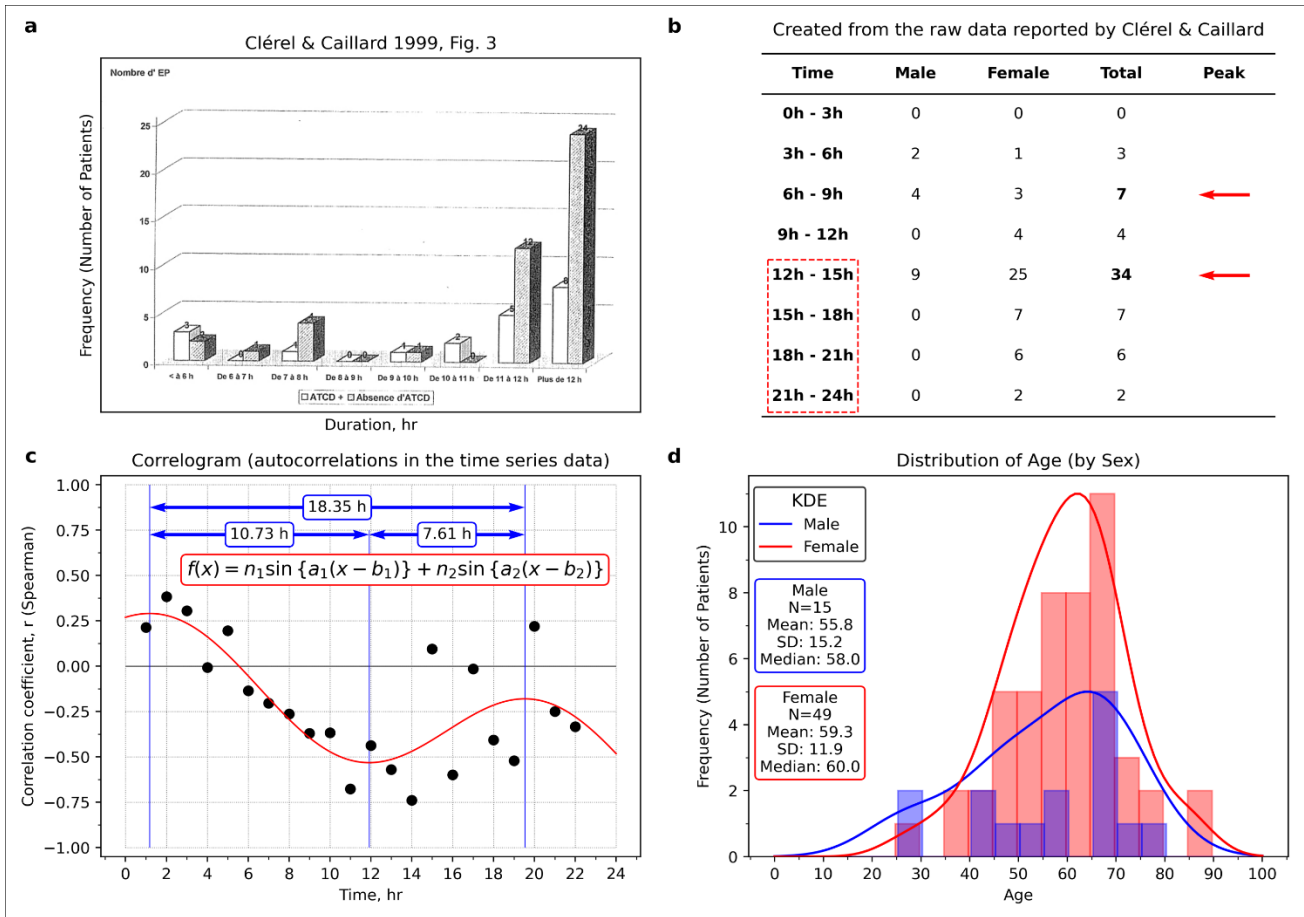

977 the time category (see Methods). Philbrick et al.⁴ reported the result of a systematic review with a table (list).

978 In contrast, this visualising allows us to extract latent information.

979

980

981 **Extended Data Fig. 4**

982

983 **Extended Data Fig. 4 | Re-analysis of the data in Table 1 by Clérel & Caillard²⁷.** a, A figure made by

984 Clérel & Caillard²⁷ showed a relationship between travel time and the thrombosis onset in the case of

985 stratification by medical history of thrombosis. b, The relationship between time and thrombosis (prepared

986 from Table 1 reported by Clérel & Caillard²⁷). c, Correlogram (prepared from Table 1 reported by Clérel &

987 Caillard²⁷). d, Age distribution by sex (made from Table 1 reported by Clérel & Caillard²⁷). As shown in panel

988 a, Clérel & Caillard²⁷ summarised all the data for 12 hours or more, but there were two peaks (see panel b).

989 Judging from the age distribution (panel d), the number of women patients was more significant than that of

990 men, but there was no difference between the age ranges. In panel c, there was a periodic pattern. Panel a
991 reproduced from Clérel & Caillard. Syndrome thrombo-embolique de la station assise prolongée et vols de
992 longue durée: l'expérience du Service Médical d'Urgence d'Aéroports De Paris. *Bull Acad Natl Med.* 1999;
993 183(5):985-997. discussion 997-1001. Figure 3.

1010 confirm this figure adaptation. Also, we obtained permission to re-use.

1011

1012

1013

1014 **Extended Data Fig. 6**

1015

1016 **Extended Data Fig. 6 | Thrombosis reported by Clérel & Caillard²⁷ & our novel annotations. a, Clérel &**

1017 Caillard mentioned that "their incidence increases during the last years, corresponding to the growth of air

1018 traffic and mainly to the increase of long duration without stop flight."²⁷ **c, Chronology of various guidelines**

1019 on HRT. In the newly figure (panel b), the increase in thrombosis was associated with the issuance time of

1020 guidelines for HRT. HRT was recommended for menopausal women in the 1990s, but its effectiveness was

1021 questioned in the HERS trial (1998)³¹. Also, the risk was discovered in the WHI trial at the interim analysis

1022 (2002)³². It might be the effect of the publication on the HERS study (1998)³¹ that the increase of thromboses

1023 was relatively small in 1998 despite the publication of two documents recommended in 1997. Panel a was
1024 reproduced from Clérel & Caillard. Syndrome thrombo-embolique de la station assise prolongée et vols de
1025 longue durée: l'expérience du Service Médical d'Urgence d'Aéroports De Paris. *Bull Acad Natl Med.* 1999;
1026 183(5):985-997. discussion 997-1001. Figure 1.

1079 origin of the coordinate system). **g**, Group 2 in the small coordinate system. **h**, Group 3 in the small coordinate
1080 system. In panel f-h, the upper curve is expressed by a quadratic function, in which a coefficient of the
1081 quadratic term is equal to a value of the coefficient of the quadratic term for the solid curve multiplied by $3/2$.
1082 In the lower curve, a coefficient of the quadratic term of the solid curve multiplied by $2/3$. Most data points
1083 located inside the crescent-shaped region enclosed by the parabolas, but the reason was unclear. Panel a was
1084 re-used from Guo T et al. *JAMA Cardiol.* 2020; 5(7):811-818. Figure 1B

1092

1093 **Extended Data Fig. 10**

1094

1095 **Extended Data Fig. 10 | A three-dimensional plot reconstructed from the data reported by Guo et al³⁵.**

1096 **a**, Scatter plot showing the relationship between high sensitive C-reactive protein (hsCRP) and troponin T

1097 (TnT)³⁵. **b**, Re-drawn scatter plot with a vertical line around hsCRP = 200 mg/mL = 2.0×10^2 mg/mL. **c**,

1098 Enlarged subgroup 3 in the panel d of Extended Data Fig. 9 (data exceeding hsCRP = 200 mg/mL are

1099 indicated by red, data not exceeding hsCRP = 200 mg/mL are indicated by blue). **d**, Enlarged subgroup 3 of

1100 the panel d in Extended Fig. 9 with the foot of the perpendicular from each data point to the parabola. **e**, The

1101 hsCRP value of each patient placed on panel d (shown as a three-dimensional plot). **f**, The side surface of the

1102 parabolic cylinder. The point of $TnT = 1.31$ observed in panel b is not included in panel c, and the point of
1103 $TnT = 1.71$ in panel c is not included in panel b (inconsistent). In panel e, the projection of the data points
1104 onto the parabola was used as new points. In panels, e and f, some points of CRP value could not be
1105 determined because of overlapping, so those points were replaced with the average value (the points indicated
1106 by the left-pointing arrows and the error bar, which are the average values and the range of values,
1107 respectively). Panel a was re-used from Guo et al. *JAMA Cardiol.* 2020; 5(7):811-818. Figure 1.
