24  
25 **Abstract**

26 **Background**

27 In Italy, population-based screening programs for breast, cervical and colorectal cancers are mandatory,  
28 and Regions are in charge of their delivery. From March to May 2020, a severe lockdown was imposed due  
29 to the Covid-19 pandemic by the Italian Ministry of Health, with the suspension of screening programs. This  
30 paper describes the impact of the pandemic on Italian screening activities and test coverage in 2020.

31 **Methods**

32 The regional number of subjects invited and of screening tests performed in 2020 were compared with  
33 those in 2019. Invitation and examination coverage were also calculated. PASSI surveillance system,  
34 through telephone interviews, investigated the population screening test coverage, before and during the  
35 pandemic, accordingly to educational attainment, perceived economic difficulties and citizenship.

36 **Results**

37 A reduction of subjects invited and tests performed, with differences among periods and geographic macro  
38 areas, was observed in 2020 vs. 2019. The reduction in examination coverage was larger than that in  
39 invitation coverage for all screening campaigns. From the second half of 2020, the trend for test coverage  
40 showed a decrease in all the macro areas for all the screening campaigns. Compared with the pre-pandemic  
41 period, there was a greater difference according to level of education in the odds of having had a test last  
42 year vs. never having been screened or not being up to date with screening tests. In addition, foreigners  
43 had less access to screening than Italians did.

44 **Conclusions**

45 The lockdown and the ongoing Covid-19 emergency caused an important delay in screening activities. This  
46 increased the pre-existing individual and geographical inequalities in access. The opportunistic screening  
47 did not mitigate the pandemic impact.

48 **Funding**

49 This study was partially supported by Italian Ministry of Health – Ricerca Corrente Annual Program 2023.

## 52 **Background**

53 The Covid-19 pandemic and the measures taken by most governments to control the spread of the virus  
54 had an impact on all health services, but also on people's behaviors and attitudes toward prevention<sup>1,2</sup>.

55 The combination of reduced health service delivery for non-Covid-19 activities and a lower propensity to  
56 access health services by the population caused appreciable delays in cancer diagnosis in most countries  
57 where the phenomenon has been studied.<sup>3 4 5</sup>

58 Screening programs are non-urgent services and thus they were among the first suspended during the first  
59 pandemic wave in most European countries.<sup>6</sup> On the other hand, active invitation allows to accurately plan  
60 the workload, which represented an opportunity for organized screening programs to resume post-  
61 lockdown activities in a rational way according to accurate prioritization, aiming to minimize the impact of  
62 the pandemic on cancer diagnosis delays.<sup>7, 8</sup> Thus, the presence of a structured and well-organized  
63 screening program has been recognized as an element favoring the resilience of health services to the  
64 pandemic disruption.<sup>9</sup>

65 In Italy, a national law included organized screening programs for breast, cervical, and colorectal cancers  
66 among the public health interventions that all the Regions must carry out[ref].<sup>10</sup> The target population, the  
67 test, and the intervals used are reported in box 1. Before the Covid-19 pandemic, the invitation coverage  
68 was almost complete for all screening programs in Central Italy, and for breast cancer in Northern Italy,  
69 while for colorectal cancer screening, there were still areas - especially in Southern Italy - where large parts  
70 of the target population was not actively invited. There are large differences in participation to all three  
71 screening programs among regions, with the Northern regions achieving higher participation rates than the  
72 Southern ones. Routine statistics on activity and performance indicators are produced by the National  
73 Screening Monitoring Center (ONS), which is a technical network appointed by the Italian Ministry of  
74 Health to monitor regional screening campaigns, and they are available at  
75 [www.osservatorionazionale screening.it](http://www.osservatorionazionale screening.it).

76 Across the country, opportunistic screening - offered by both private and public providers - is common and  
77 does not have a specific informative flow for reporting and monitoring. Opportunistic screening accounts  
78 on average for one fourth, one third, and one sixth of the screening test coverage in the target population  
79 that reaches 75%, 80%, and 48%, for breast, cervical, and colorectal cancer, respectively.<sup>11</sup>

80 In Italy, the first diagnosis of Covid-19 was made on February 20, 2020, and a strict lockdown started on  
81 March 8.<sup>12</sup> The impact of this first wave in terms of deaths was very strong and concentrated in Northern  
82 Italy. A second wave started in October and lasted until the end of the year, involving all the Italian regions.  
83 Control measures differed in the three periods: from March to May, the lockdown stopped all non-essential  
84 activities; during the summer, almost all restrictions were removed; while during the October to December  
85 restrictions, school closures, limits to movement and recommendations to work from home were applied  
86 on a regional or even provincial basis according to incidence.<sup>13</sup>

87 The aim of this paper is to describe the impact of the pandemic and infection control measures on the  
88 activities of Italian screening programs in terms of invitations and screening tests performed during the first  
89 year of the pandemic and to investigate how this impacted the population screening test coverage.

90

## 91 **Methods**

92 *Setting and description of the infection control measures adopted in screening programs*

93 In Italy, breast, cervical, and colorectal cancer screenings are recommended, and regional health systems  
94 are in charge of implementing them according to the recommendations of the European Commission and  
95 of the Italian Ministry of Health. The target ages, intervals and test modalities recommended in Italy are  
96 reported in box 1.<sup>14,15</sup>

97 After the first case diagnosed on February 20, apparently small clusters were identified and restrictions on  
98 movement in small areas in Northern Italy were set. On March 9, the first lockdown measures were put in  
99 place for the whole country, causing the suspension of screening first level activities and maintaining  
100 diagnostic assessment in those who tested positive.<sup>16,17</sup> Regardless of national provisions, the suspension  
101 was heterogeneous: it was almost complete in most Northern and Central regions where screening  
102 invitations and test delivery were immediately suspended; in Lazio, the suspension was established late;  
103 while in other regions, according to screening organization, test delivery was maintained for colorectal

104 (Puglia, Umbria) and cervical (Valle D’Aosta) cancer campaigns. Assessment of people who had previously  
 105 had a positive screening test was never stopped. The strict lockdown, i.e. the “stay at home” period in  
 106 which only essential activities were allowed, ended at the beginning of May 2020, but the restrictions were  
 107 gradually removed until the beginning of June 2020, when only physical distancing and wearing face masks  
 108 remained mandatory.<sup>12</sup> Most screening programs started again in May/June, but rules to reduce the risk of  
 109 infection required avoiding crowding in waiting rooms and physical distancing in the clinics, thus the  
 110 number of exams per hour was reduced by 30 to 50% in all programs. These restrictions lasted for the  
 111 entire study period. During the summer, Covid-19 incidence remained relatively low throughout the  
 112 country, but in October it increased rapidly and new restrictions were introduced.<sup>13</sup> Regions or provinces  
 113 were classified as white, yellow, orange, and red according to a set of indicators measuring the quality of  
 114 data reporting, the testing capacity, the incidence trend (the Rt), the adequacy of contact tracing, and the  
 115 pressure on the health system.<sup>18</sup> Each color code corresponded to a set of mandatory restrictions that the  
 116 regional government should implement and eventually integrate with local measures. Among these  
 117 measures, none were directed to reduce non-urgent health services and, in several regions, cancer  
 118 screening had been included among the services which had to be maintained. Nevertheless, in many areas,  
 119 the pressure on hospitals became so strong that it became necessary to reduce non-urgent activities in  
 120 order to re-direct health professionals to Covid-19-related activities. Furthermore, in orange and red zones  
 121 there were restrictions on moving from one municipality to another (even if these did not apply for medical  
 122 checks/reasons) and restrictions on public transport, thus making it more difficult for invited people to  
 123 attend screening appointments.

124  
125

Box 1. Italian Ministry of Health recommendations for cancer screening programs.

	Target population	Test	Interval
Cervical cancer	Women 25 to 64yy	Pap test (25 to 29/34 yy) HPV test (30/35 to 64 yy)	3yy after negative Pap 5yy after negative HPV
Breast cancer	Mandatory: Women 50 to 69 yy Suggested: Women 45 to 49 yy Women 70 to 74 yy	Mammography	2yy for women 50 to 74 1y for women 45 to 49
Colorectal cancer	Mandatory: Women and men 50 to 69 yy Suggested: Women and men 70 to 74 yy	Fecal immunochemical test (FIT) or Sigmoidoscopy at 58/60 yy	2yy after negative FIT Once in a life sigmoidoscopy

126  
127

#### Data sources

128 The National Screening Monitoring Center (ONS) monitors regional screening performances and trends,  
 129 and a summary report is regularly published  
 130 (<https://www.osservatorionazionale screening.it/content/rapporto-ons-2020>). In October 2020, the ONS  
 131 promoted an additional survey to monitor the impact of the pandemic on screening programs.<sup>19,20</sup>  
 132 An ad hoc quantitative questionnaire was sent by the ONS to all regional cancer screening coordinators in  
 133 order to collect - within breast, cervical and colorectal screening programs - an absolute number of subjects  
 134 invited and an absolute number of screening tests performed for the periods of January-May 2020, June-  
 135 September 2020, October-December 2020, and January-May 2021 compared to those of the same periods  
 136 over 2019.  
 137 Data were referred to the core target population, i.e., the age group that is mandatory for all regions (see  
 138 box 1).  
 139 Twenty-one regions out of 21 participated in the survey. It must be noted that: the results of two out of five  
 140 programs in Calabria are missing; the data from Basilicata refer to the whole period of the study, thus sub-  
 141 periods are excluded from analyses; the colorectal cancer screening data from Umbria refer to the 50-74-  
 142 year-old target population rather than 50-69.  
 143

144 PASSI survey is one of the two National Health Interviews (NHIS) active in Italy .<sup>11,21</sup> Through a continuous  
145 sampling of the resident population, it conducts telephone interviews collecting information about health  
146 behaviors, use of health services and participation in preventive interventions.<sup>22 23</sup> It also collects data on  
147 socioeconomic characteristics of the people interviewed: educational attainment (4 categories: elementary  
148 school; middle school; high school; higher education), perceived economic difficulties (3 categories: many  
149 economic difficulties; some economic difficulties; no economic difficulties) and citizenship (2 categories:  
150 Italians with foreign nationals from high-income countries; foreign nationals from middle or low-income  
151 countries - according to the World Bank classification (UNDP, 2007)). Participation in the survey is free and  
152 voluntary, individuals can refuse to be interviewed or can interrupt the interview at any time. The  
153 interviewers are specifically trained to safely and correctly process personal data. Individuals selected for  
154 the interview are informed by letter about the objectives of the investigation, its methods and the  
155 arrangements taken to ensure the confidentiality of the collected information. After receiving the letter,  
156 they are contacted by phone; during the phone interview the interviewer presents the information again  
157 and asks for the interviewee's consent to conduct the interview.  
158 In the present study, the analyzed data were collected by PASSI between 2017 and 2021, from interviews of  
159 more than 106,000 people, a representative sample of the Italian population aged 25–69, except for the  
160 Lombardy region that suspended the surveillance in 2016.

### 161 162 *Outcomes definition*

163 Based on the ONS survey, we report the number of the invitations sent during the investigation period and  
164 the number of the screening examinations performed in the study period. Invitation (percentage of citizens  
165 who were sent an invitation to a screening during the analyzed period, compared to the target population,  
166 excluding undelivered invitations and non-eligible subjects) and examination (percentage of citizens who  
167 performed the test compared to the target population excluding those with specific exclusion criteria)  
168 coverage relatively to 2017-2019 is also reported.

169 We also computed the “standard months” of delay, i.e., the number of months that would be required to  
170 catch up the cumulated backlog if the program screened women at the same pace it did over the pre-  
171 COVID era. This parameter is obtained by multiplying the reduction in the number of tests performed  
172 during the study period as compared to the same period in 2019 (% reduction), by the duration (number of  
173 months) of the study period.

174  
175 Based on the date of the last test before the PASSI interview and the reported provider of the last test (free  
176 or paid out of pocket, proxy of organized and spontaneous screening, respectively), we computed the test  
177 coverage for each screening program: for breast cancer, we considered as being eligible the female  
178 population aged 50 to 69 and those who reported having had a mammogram in the last two years as up-to-  
179 date with screening; for cervical cancer, we considered as being eligible the female population aged 25 to  
180 64 and those having had a Pap test in the last three years or an HPV-DNA test in the last five years as up-to-  
181 date with screening; for colorectal cancer, we considered as being eligible males and females aged 50 to 69  
182 and those reporting a faecal occult blood test (FOBT) in the last two years or a colonoscopy or  
183 sigmoidoscopy in the last five years as up-to-date with screening.

184 We also only considered the tests performed in the last year as an outcome for each screening test.

### 185 186 *Statistical analysis*

187 For the ONS surveys, only descriptive analyses are presented.

188 In PASSI, each Local Health Authority extracts a proportionate stratified sampling for the sex and age  
189 categories (18–34,35–49, 50–69 years) of the resident population. Therefore, data analysis at a national  
190 and macro-area level requires the application of appropriate weights accounting for age and geographic  
191 stratification to be representative of the whole population.

192 Trends of coverage are computed for each quarter of the study period, including interviews from January  
193 2008 up to December 2020 for cervical and breast cancer and from January 2010 to December 2020 for  
194 colorectal cancer screening because the relevant items in the questionnaire were changed in 2010.

195 Using the tests performed in the last year as a dependent variable, we present Poisson regression models  
196 reporting the odds of having had a test in the last year vs. the odds of not having the test in the last year.  
197 Prevalence rate ratios with relative 95% confidence interval (95%CI) for age, gender, educational  
198 attainment, nationality and economic difficulties are obtained. Models are performed on interviews  
199 conducted in 2020 and for those conducted in the 2017-2019 period.  
200 The statistical package Stata 16 software (StataCorp LP) was used to analyze the data.

201

#### 202 *Ethics and data sharing*

203 In the PASSI surveillance system, personal data are processed in compliance with the GDPR 2016. PASSI was  
204 approved by the Ethics Committee of the National Institute of Public Health on January 23, 2007. Interviews  
205 are transferred anonymously to a national archive via a secure internet connection. Personal Identifiers on  
206 paper or computers are subsequently locally destroyed.

207 Although the anonymized dataset is not yet available, the National Institute of Health is working to make it  
208 available on request (<http://www.epicentro.iss.it/passi/PresPolicy.asp>).

209

## 210 **Results**

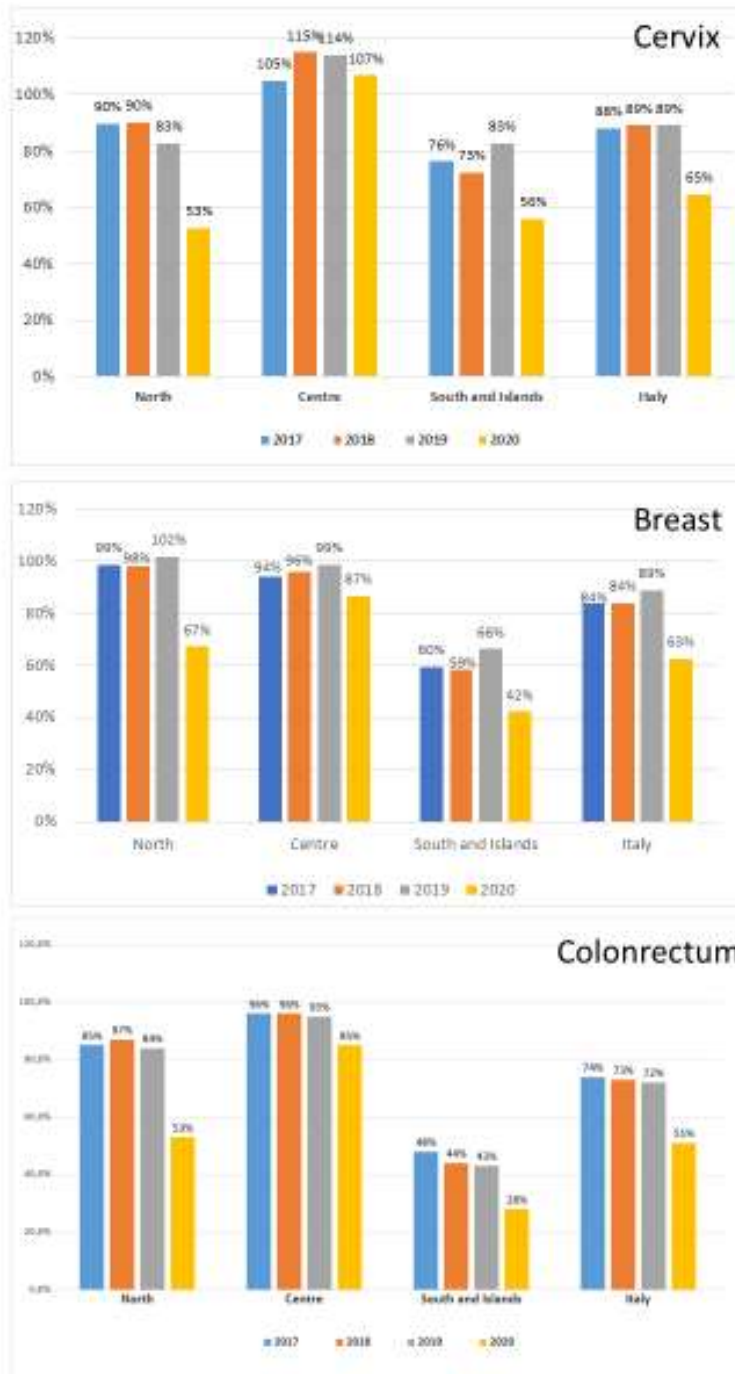

### 211 *Impact on screening programs*

212 In 2020, the screening invitations decreased, for cervical, breast and colorectal cancer screening in  
213 Northern and Southern Italy, compared with those of the 2017-2019 period. It is worth noting that Central  
214 Italy registered the best performances: cervical cancer screening programs were indeed able to maintain  
215 the invitation coverage close to 100% and breast and colorectal cancer screening resulted just below the  
216 cut off of 90% (Figure 1).

217

218  
219  
220  
221  
222  
223  
224  
225  
226

Figure 1. Invitation coverage for cervical, breast and colorectal cancer screening in Italy, by year and geographical macro area. The coverage is computed as the number of the invitations sent during the year divided by the expected target population to be invited in one year. For breast and colorectal cancer, the target population is expected to be invited in two years, for cervical cancer the target population is expected to be invited every three years if last test was a Pap test and every five years if the last test was an HPV test.

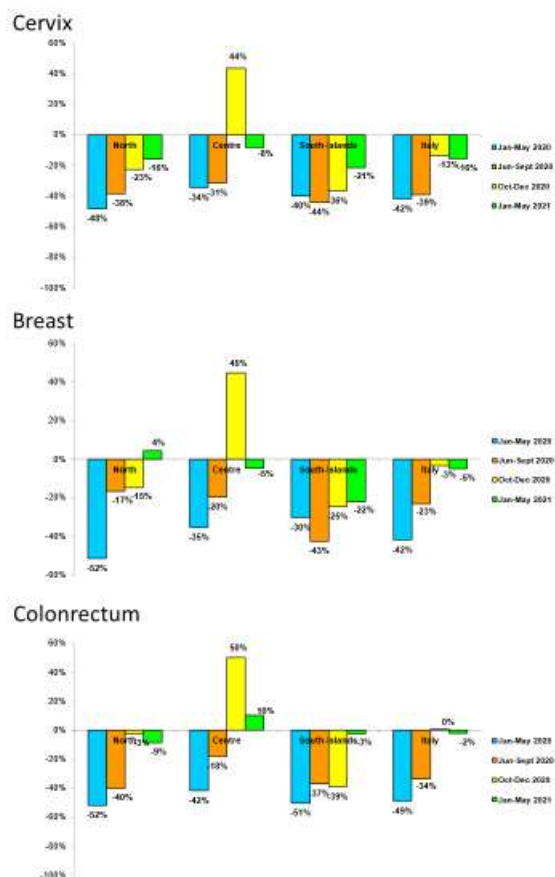

227

228 The reduction in invitations was large and consistent in all macro areas and all screening programs for the  
 229 first (January to May 2020) and second (June to September 2020) period. In the third one (October to  
 230 December 2020) differences emerged: in Central Italy, programs tried to catch up the backlog of invitations,  
 231 while in Northern Italy the programs mostly continued with the pre-pandemic pace. In Southern Italy the  
 232 reduction in activity remained up to the first quarter of 2021, except for colorectal cancer screening (Figure  
 233 2).

234  
 235 Figure 2. Percent changes in the number of invitations sent by screening programs in 2020-21 compared to  
 236 2019, by period and geographic macro area.

237  
 238

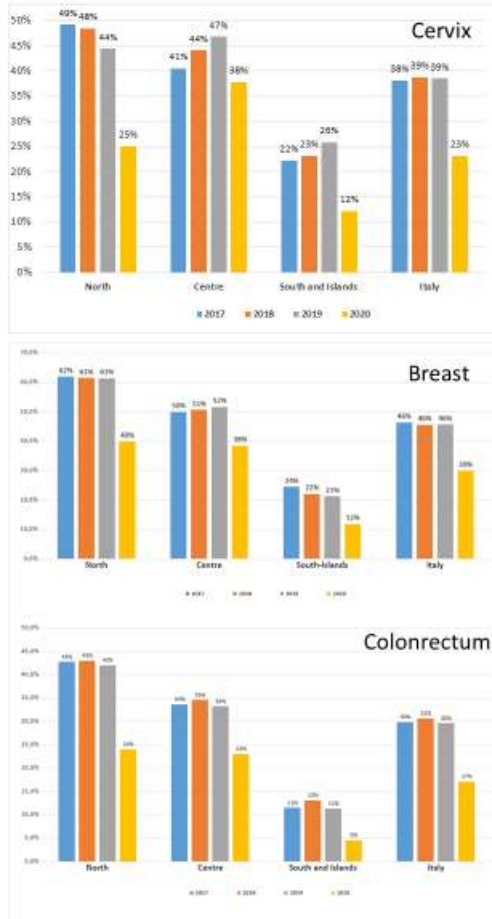

239 Compared to 2017-2019, in 2020 the reduction in examination coverage was larger than the reduction in  
 240 invitation coverage for all screenings and in all macro areas (Figure 3). In Central and Northern Italy, it was  
 241 particularly strong in the first period and then decreased gradually (Figure 4), reaching pre-pandemic levels  
 242 for breast and colorectal cancer screening in the first quarter of 2021, but not for cervix cancer screening in  
 243 Northern Italy. In Southern Italy, the reduction in tests performed lasted until the end of 2020 and it is still  
 244 strong for cervical and breast cancer screening in the first quarter of 2021 (Figure 4).

245

246

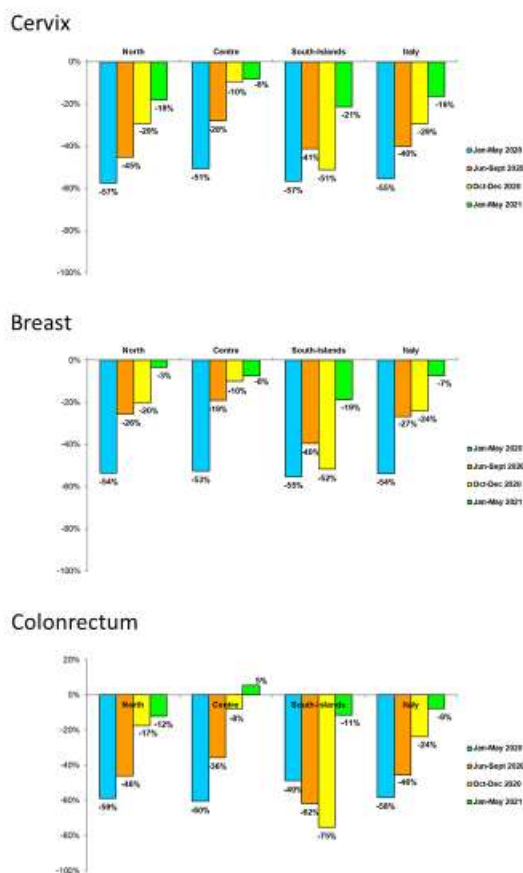

247 Figure 3. Test coverage for cervical, breast and colorectal cancer screening in Italy, by year and geographical  
 248 macro area. The coverage is computed as the number of the tests sent during the year divided by the  
 249 expected target population to be tested in one year. For breast and colorectal cancer, the target population  
 250 is expected to be screened in two years, for cervical cancer the target population is expected to be  
 251 screened every three years if last test was a Pap test and every five years if the last test was an HPV test.  
 252

253  
 254

255 Figure 4. Changes in the number of screening tests performed by screening programs in 2020-21 compared  
 256 to 2019, by period and geographic macro area.  
 257

258  
 259 The delay accumulated until May 2021 in screening the target population differs by macro area, and it is  
 260 larger for Southern Italy and smaller for Central Italy for the three programs. Despite the fact that the  
 261 efforts in restarting invitations were dissimilar, the difference in delay between breast and cervical cancer  
 262 was only of 1.2 months. Ranges between regions within macro areas are important. In fact, in Northern and  
 263 Central Italy one or more regions cumulated a negligible delay of less than 45 days, while some regions  
 264 cumulated about one year of delay in all programs (Table 1).

265  
266  
267

269

### 270 *Impact on overall screening test coverage*

271 The trend for test coverage as reported by PASSI showed a clear decrease in all the macro areas for the  
272 mammographic and colorectal screenings starting from the second half of 2020 (Figure 5). Also, for  
273 coverage with Pap tests or HPV tests the decrease is appreciable, but the magnitude is smaller. It is also  
274 appreciable that in 2020 we had an inversion in a long-term trend, with a decrease of opportunistic  
275 screening in favor of organized screening for cervical cancer (Figure 6).  
276

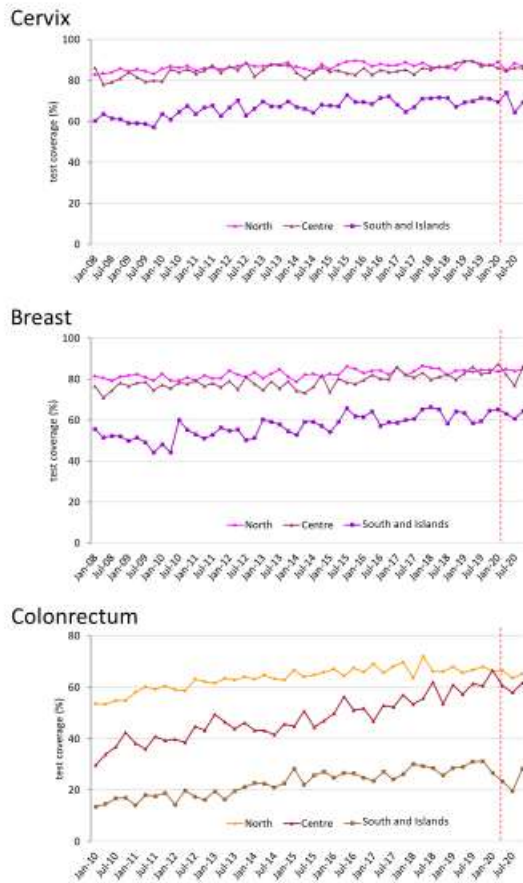

277 Figure 5. Trends of the proportion of the screening target population who declared to have had a test in  
278 due time, overall and by setting of the last test performed. For breast cancer, we considered as being  
279 eligible the female population aged 50 to 69 and those who reported as having had a mammogram in the  
280 last two years as up-to-date with screening; for cervical cancer, we considered as being eligible the female  
281 population aged 25 to 64 and those having had a Pap test in the last three years or an HPV-DNA test in the  
282 last five years as up-to-date with screening; for colorectal cancer, we considered as being eligible males and  
283 females aged 50 to 69 and those who reported as having had a FOBT in the last two years or a colonoscopy  
284 or sigmoidoscopy in the last five years as up-to-date with screening. Data from the PASSI interviews.  
285

286

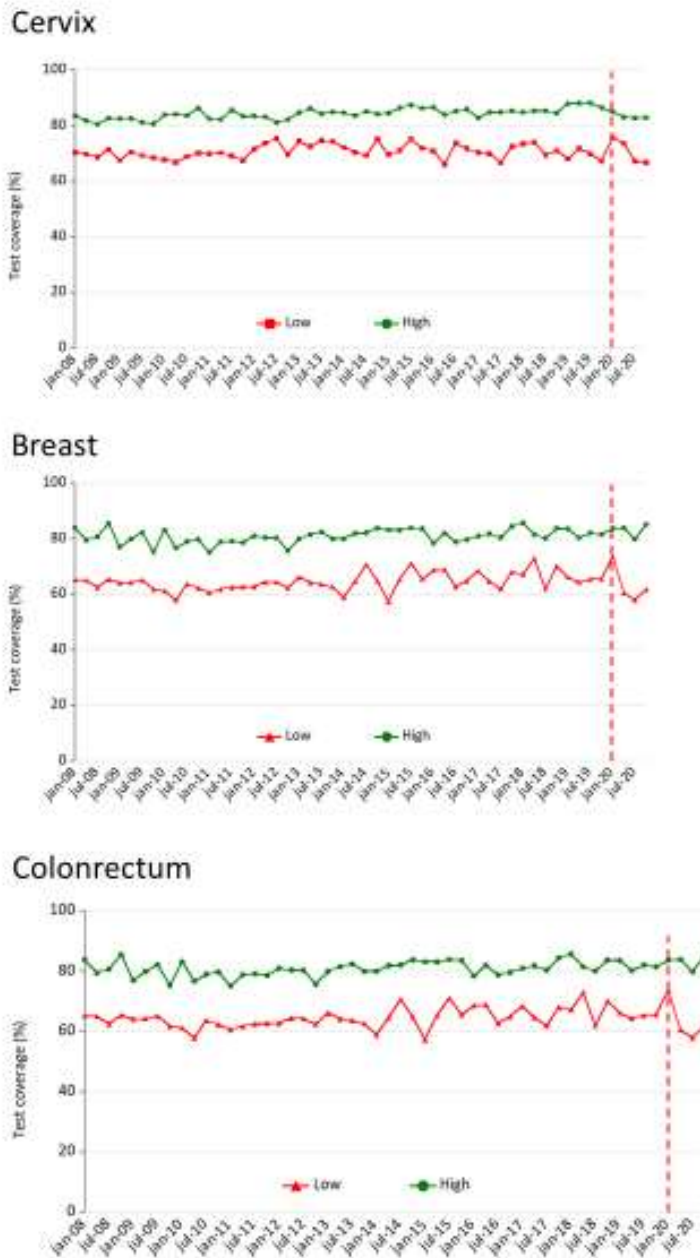

287

288 Figure 6. Trends of the proportion of the screening target population who declared to have had a test in  
289 due time, by geographical macro area. For breast cancer, we considered as being eligible the female  
290 population aged 50 to 69 and those who reported as having had a mammogram in the last two years as up-  
291 to-date with screening; for cervical cancer, we considered as being eligible the female population aged 25  
292 to 64 and those having had a Pap test in the last three years or an HPV-DNA test in the last five years as up-  
293 to-date with screening; for colorectal cancer, we considered as being eligible males and females aged 50 to  
294 69 and those who reported having had a FOBT in the last two years or a colonoscopy or sigmoidoscopy in  
295 the last five years as up-to-date with screening. Data from the PASSI interviews.  
296

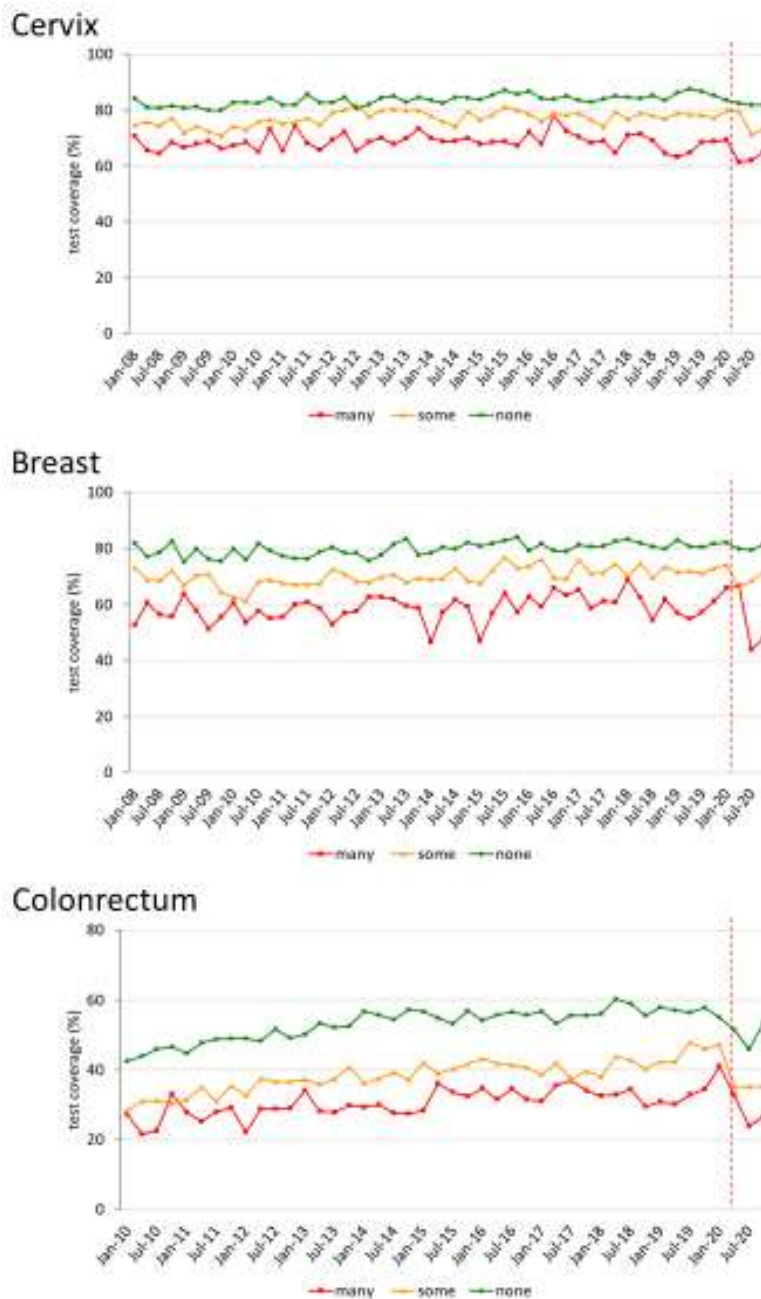

297 The decrease in test coverage is steeper in people with a lower level of educational or with many perceived  
298 economic difficulties (Figures 7,8). For cervical cancer, the proportion of women aged 25-64 that declared  
299 to have a test in the last year decreased dramatically for the screening program and at a lesser extent for  
300 opportunistic tests. For breast and colorectal cancer, the reduction was smaller and all attributable to  
301 organized screening (Figure 9).  
302  
303  
304

305 Figure 7. Trends of the proportion of the screening target population who declared to have had a test in  
306 due time, by perceived economic difficulties. For breast cancer, we considered as being eligible the female  
307 population aged 50 to 69 and those who reported as having had a mammogram in the last two years as up-  
308 to-date with screening; for cervical cancer, we considered as being eligible the female population aged 25  
309 to 64 and those having had a Pap test in the last three years or an HPV-DNA test in the last five years as up-  
310 to-date with screening; for colorectal cancer, we considered as being eligible males and females aged 50 to  
311 69 and those who reported as having had a FOBT in the last two years or a colonoscopy or sigmoidoscopy in  
312 the last five years as up-to-date with screening. Data from the PASSI interviews.  
313

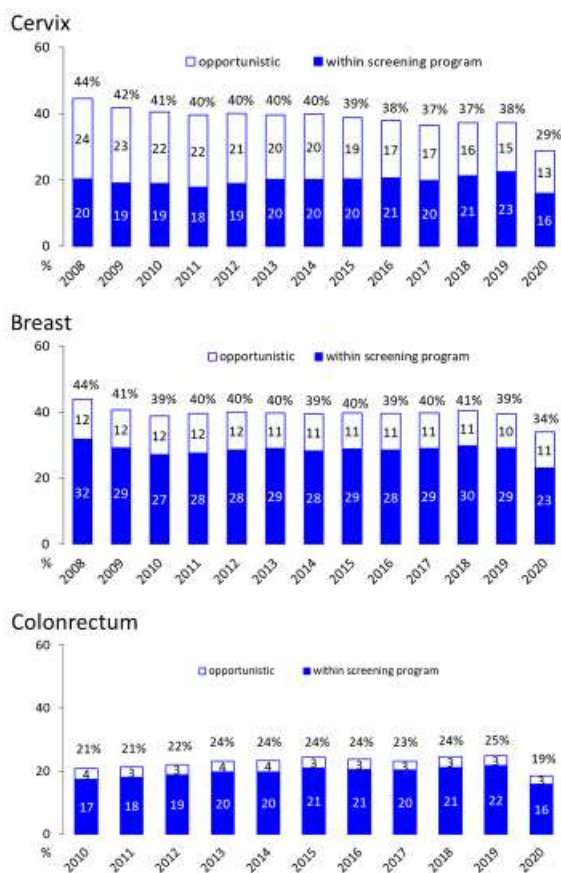

314  
315  
316

317 Figure 8. Trends of the proportion of the screening target population who declared to have had a test in  
318 due time, by citizenship (Italian plus foreign nationals from high-income countries and foreign nationals  
319 from middle or low-income countries, according to the World Bank classification (UNDP, 2007)). For breast  
320 cancer, we considered as being eligible the female population aged 50 to 69 and those who reported as  
321 having had a mammogram in the last two years as up-to-date with screening; for cervical cancer, we  
322 considered as being eligible the female population aged 25 to 64 and those having had a Pap test in the last  
323 three years or an HPV-DNA test in the last five years as up-to-date with screening; for colorectal cancer, we  
324 considered as being eligible males and females aged 50 to 69 and those who reported as having had a FOBT  
325 in the last two years or a colonoscopy or sigmoidoscopy in the last 5 years as up-to-date with screening.  
326 Data from the PASSI interviews.

 331 year and setting where the test was last performed. Data from the PASSI interviews.

332  
 333

334 In 2020, the odds of having had a test in recent years vs. never having been screened or not being up to  
 335 date with screening tests, showed larger differences according to level of educational than in the pre-  
 336 pandemic period, for the three screenings (Table 2). Furthermore, in 2020, for breast cancer screening only  
 337 foreigners had a lower probability of having had a test than Italians, inverting what was observed in the  
 338 pre-pandemic period (Table 2). The other differences remained substantially unchanged in the pandemic  
 339 compared with the pre-pandemic period.

## 344 Discussion

345 The interruption of screening programs during lockdown over March - May 2020, as well as the reduction in  
346 their activity in the following months caused, on average, a delay of at least six months for cervical cancer,  
347 five months for breast cervical, and six months for colorectal cancer screening. There are large differences  
348 in the cumulated delay between macro areas and, within macro areas, between regions (Table 1) and local  
349 health authorities.<sup>9,35</sup> The largest delays are observed in those areas where screening programs had  
350 historical problems in extending invitations to the whole target population and participation was already  
351 low before the pandemic - particularly in Southern Italy but also in some areas of Northern Italy - where  
352 cervical cancer screening was recently implemented and coverage relied largely on opportunistic screening  
353 .<sup>21 24 25</sup> Northern Italy was also the most affected area by the pandemic.

354 It is worth noting that the decrease in screening tests performed by screening programs was larger than the  
355 decrease in invitations. Even if the surveys conducted by the National Screening Monitoring Center were  
356 not designed to measure participation, this difference in the decrease indirectly shows that participation  
357 decreased during the study period.

358 Stopping screening programs and their slow restart caused an appreciable decrease in test coverage in the  
359 target population of breast and colorectal cancer. This decrease is smaller, as expected, for cervical cancer  
360 screening because the longer screening intervals reduce the impact of the period of absent or reduced  
361 activity; nevertheless, a change in the direction of the trend is also appreciable for cervical cancer  
362 screening. While for colorectal screening the contribution of opportunistic screening was negligible before  
363 and during the pandemic, for breast and cervical cancer opportunistic screening did not increase the  
364 proportion of population test coverage and only a small peak of women reporting having paid for a test was  
365 appreciable in the strict lockdown period of March-May 2020.

366 The decrease in test coverage provided by organized screening programs caused an increase in inequalities.  
367 In fact, people with a lower level of educational and immigrants paid the largest lack of access to secondary  
368 prevention during the pandemic.

369 Other studies reported an early disruption of screening activities following the lockdown, with invitations  
370 and first level tests being stopped, and a reduction in participation when invitation restarted.<sup>26 27 28 29 30</sup>

371 The reported data show large differences across countries in the screening programs' ability to resume  
372 their activity and in catching up with the cumulated backlog. Italy has a federal health system in which  
373 implementation of screening programs is delegated to the regional government and practically managed by  
374 the local health authorities. This organizational model together with historical differences in the robustness  
375 of screening programs and the population's trust in the public health system resulted in an extreme  
376 variability in the delay cumulated in more than one year of Covid-19 emergency.<sup>25</sup> In fact, some areas  
377 showed the ability to recover all the backlog, while the vast majority were still cumulating further delay in  
378 the first months of 2021. These differences increased the already existing geographical inequalities across  
379 the country.

380 As a consequence, individual inequalities are also going to increase. In fact, the difference by educational  
381 level were much stronger in 2020 than in previous years; furthermore, differences disadvantaging  
382 immigrants - that were not appreciable in previous years - were observed in the access to screening tests  
383 particularly for breast cancer screening in 2020, probably because immigrants rely mostly on organized  
384 screening and scarcely on opportunistic screening. Studies from the US also showed increased inequalities  
385 consequent to the screening program interruption, with a larger impact in the decrease of screening uptake  
386 in rural areas and for beneficiaries of public insurance or those who are not insured at all.<sup>31, 32</sup>

### 388 *Possible impact*

389 Many studies from Italy and other countries reported a delay in diagnoses for many cancer sites.<sup>33,34</sup> In  
390 some studies, a shift to more advanced stages and different initial therapeutic approaches have been  
391 observed for breast cancer and colorectal cancers.<sup>35 36 37 38 39</sup> Investigating the impact on cancer stage is  
392 out of the scope of this study. Nevertheless, computing the expected delay cumulated up to now can give  
393 an estimate of the impact on mortality and, for cervical and colorectal cancer, on incidence. In fact, several  
394 mathematical models have been adapted precisely for to this scope. For breast and colorectal cancer, in  
395 England, a model assuming a 12-month suspension of screening and early diagnosis pathways and

396 reallocating all diagnoses to symptomatic diagnosis estimated an excess of about 300 breast cancer deaths  
397 (8-10% increase) and 1500 colorectal cancer deaths (15-17%) in the next five years<sup>40</sup>. The expected health  
398 impact of the disruption may be larger for clinical than for screening services. The results of simulation  
399 models focused on the analysis of the impact of screening programs disruption are suggesting that we can  
400 expect a relative increase in breast and colorectal cancer specific mortality ranging between 1% and 3%  
401 over the next 10 to 30 years, depending on the duration of the disruption and on the catch-up strategies  
402 adopted. More than half of the excess deaths are expected to occur during the first 5 to 10 years following  
403 disruption and the health impact might be larger for older people and disadvantaged population  
404 subgroups. For cervical cancer, it has been estimated that a delay of six months national screening program  
405 would lead to about 600 more cancers in England that would occur in the next screening round, in the  
406 absence of catch-up strategies.<sup>7, 41</sup> We can expect a similar impact of screening disruption in Italy, where  
407 we observed a wide variability in the length of disruption, with a 6-month average delay in the invitations.<sup>42</sup>  
408 <sup>43 44</sup>

#### 409 **Conclusions**

410 The lockdown and the ongoing Covid-19 emergency caused an important delay in screening activities. This  
411 increased the pre-existing individual and geographical inequalities in access. The opportunistic screening  
412 did not mitigate the pandemic impact.

413

414

#### 415 **Funding**

416 This study was partially supported by Italian Ministry of Health – Ricerca Corrente Annual Program 2023.

417

418

#### 419 **Acknowledgements**

420 The authors are grateful to all the regional and local coordinators and interviewers of PASSI surveillance  
421 and to the regional screening coordinators, who contributed to the data collection. A special thanks goes to  
422 the PASSI group for their competence and commitment.
