Summary

The SARS-CoV-2 Omicron variant has challenged the control of the COVID-19 pandemic even in highly vaccinated countries. While a second booster of mRNA vaccines improved the immunity against SARS-CoV-2, the humoral and cellular responses induced by a second booster of an inactivated SARS-CoV-2 vaccine have not been studied. In the context of a phase 3 clinical study, we report that a second booster of CoronaVac® increased the neutralizing response against the ancestral virus yet showed poor neutralization against the Omicron variant. Additionally, isolated PBMCs displayed equivalent activation of specific $CD4^+$ T cells and IFN-γ production when stimulated with a mega-pool of peptides derived from the spike protein of the ancestral virus or the Omicron variant. In conclusion, a second booster dose of CoronaVac® does not improve the neutralizing response against the Omicron variant compared with the first booster dose, yet it helps maintaining a robust spike-specific $CD4^+$ T cell response.

Key words: CoronaVac®, second booster dose, SARS-CoV-2, Omicron variant, humoral immunity, cellular immunity.

Introduction.

The development of vaccines that grant long-lasting protection against SARS-CoV-2 is essential to control the current COVID-19 pandemic. Although several vaccines were developed in record time, three dynamic phenomena have prevented the global control of the COVID-19 pandemic. First, the continuous emergence of SARS-CoV-2 variants of concern (VOCs), such as Omicron (BA.1, BA.2), and its subvariants (BA.2.12.1, BA.4, BA.5) with high transmissibility and immune evasion profiles[1]. Second, the waning of neutralizing antibodies in fully vaccinated subjects[2]. Third, the difficulties to mass producing and globally distributing enough vaccines or implementing affordable and effective vaccination programs.

Several platforms have been used to develop vaccines against SARS-CoV-2[3]. Due to their novelty, mRNA vaccines (BNT162b2 and mRNA-1273) have been the most studied and are highly effective in protecting individuals from symptomatic infection, severe disease, and death[4,5]. Inactivated virus-based vaccine, a more traditional vaccine platform, has also been used to develop a SARS-CoV-2 vaccine. CoronaVac®, an inactivated vaccine developed by Sinovac Life Sciences Co., Ltd. (Beijing, China)[6], has been administered so far in 52 countries[7], showing a good safety profile in the population[8-10] and a robust immune protection against severe disease, hospitalization, and death[11].

During a phase 3 clinical trial in Chile, our group demonstrated that a two-dose vaccination schedule of CoronaVac® induced a strong neutralizing response and T cell activation against SARS-CoV-2 in adults[12]. Further studies from our laboratory determined that fully vaccinated subjects with CoronaVac® showed a strong production of neutralizing antibodies and IFN-γ production in stimulated peripheral

88 blood mononuclear cells (PBMCs) against different VOCs of SARS-CoV-2, such as
89 Alpha, Beta, Gamma, and Delta[13].
90 Different studies have reported a reduction of the neutralizing response against
91 SARS-CoV-2 in immunized subjects with BNT162b2 and mRNA1273 vaccines[14-16].
92 These studies also showed that a booster dose was required to keep an effective
93 neutralizing response against the ancestral SARS-CoV-2 (WT SARS-CoV-2) and
94 circulating variants at that time[14,15,17].
95 Consistently with the mentioned studies, our group reported a considerable
96 reduction of the neutralizing response five months after the administration of the
97 second dose of CoronaVac®, response that was recovered after the administration
98 of a booster dose of CoronaVac®[18]. Furthermore, the enhanced neutralizing
99 response initially detected against WT SARS-CoV-2 was effective against the Delta
100 variant, but showed reduced neutralization against the Omicron variant[18], which is
101 currently the most prevalent variant of SARS-CoV-2 worldwide.
102 Although previous studies have shown that a second booster with BNT162b2 and
103 mRNA1273 vaccines would prevent the decrease of neutralizing antibodies and may
104 offer protection against symptomatic disease, severe disease, hospitalization, and
105 death caused by the Omicron variant[4,19], the effect of a second booster dose of
106 CoronaVac® in the humoral and cellular response against SARS-CoV-2, with special
107 emphasis on the Omicron variant, remains to be elucidated. In the present report,
108 we study the dynamics of the humoral and cellular immune responses in individuals
109 that received a second booster of CoronaVac® 6 months after the administration of
110 a first booster of the same vaccine. Our data shows that a second booster of
111 CoronaVac® induces a strong production of antibodies with neutralizing capacities

against WT SARS-CoV-2, although it has poor activity against the Omicron variant. We also show that a second booster dose of CoronaVac® is required to keep high levels of SARS-CoV-2-specific $CD4^+$ T cells in circulation that are reactive against the WT SARS-CoV-2, the Delta, and the Omicron variants.

Results.

1. Participants, sampling and experimental applications included in the study.

From a total of 2,302 individuals enrolled in the clinical trial CoronaVac03CL (clinicaltrials.gov #NCT04651790) in Chile (November 2020- to current date) [12,13,18,20,21], 138 fully vaccinated subjects with CoronaVac® (0-28 schedule) that received two booster doses were initially considered for this study (Fig 1A). After the exclusion of 51 subjects due to SARS-CoV-2 infection during the trial or missing data, longitudinal analyses of the humoral response were performed in up to 87 subjects, whereas the cellular response was studied in a subgroup of 46 subjects (Fig 1A).

Blood samples were collected before vaccination (T1), four to seven weeks after the second dose (T2), at least 9 weeks before the first booster dose (T3), three to six weeks after the first booster dose (T4), at least nine to cero weeks before the second booster dose (T5) and four to nine weeks after second booster dose (T6) (Fig 1B).

2. Humoral response against SARS-CoV-2 induced by a second booster dose of CoronaVac®.

Neutralizing response of serum was evaluated by three different and complementary methodologies, surrogate virus neutralization test (sVNT), conventional virus neutralization test (cVNT), and pseudotype virus neutralization test (pVNT) (see method section). Consistently with previous studies[12,18], individuals vaccinated with two doses of CoronaVac® presented a significant increase in neutralizing antibodies against WT SARS-CoV-2 four weeks after the administration of the second dose when compared with the pre-immune serum (T1 vs. T2) (16.8 vs. 199.7 GMUs

p<0.0001; 2.9 vs. 21.1 GMTs p<0.0001) (Fig. 2A-B, supplementary tables 1 and 3). Then, a significant reduction in the neutralizing antibody against SARS-CoV-2 was observed three to five months (15-20 weeks) after the administration of the second dose when compared with four weeks after the administration of the second dose (T2 vs. T3) (199.7 vs. 53.1 GMUs p<0.0001; 21.1 vs. 10.0 GMTs p<0.0001) (Fig. 2A-B supplementary table 1 and 3). Consistently with other studies[14-16], the administration of a first booster dose resulted in a rapid improvement of the neutralizing response against WT SARS-CoV-2 after 4 weeks when compared with at least nine weeks before its administration (T3 vs. T4) (53.1 vs. 586.0 GMUs p<0.0001; 10.0 vs. 95.1 GMTs p<0.0001) (Fig. 2A-B supplementary table 1 and 3). Interestingly, the neutralizing capacity against WT SARS-CoV-2 observed six months (24 weeks) after the administration of the first booster dose was partially reduced in comparison to the response detected 4 weeks after the administration of the first booster dose (T5 vs. T4) (220.4 vs. 586.0 GMUs p<0.001; 54.9 vs. 95.1GMTs p>0.05) (Fig. 2A-B, supplementary table 1 and 3). Finally, 4 to 9 weeks after the administration of a second booster dose, an increase in the neutralizing response against WT SARS-CoV-2 was observed when compared with the time before the administration of the second booster dose (T5 vs. T6) (220.4 vs. 549.2 GMUs p<0.001; 54.9 vs. 149.3 GMTs p>0.05) (Fig. 2A-B, supplementary table 1 and 3). Importantly, the neutralization response against WT SARS-CoV-2 observed after the administration of the second booster dose was not significantly higher than the response induced by the first booster dose (T4 vs. T6) (586.0 vs. 549.2 GMUs p>0.05; 95.1 vs. 149.3 GMTs p>0.05) (Fig. 2A-B, supplementary table 1 and 3). This data indicates that a second booster dose of CoronaVac® is required to keep high

levels of neutralizing antibodies against WT SARS-CoV-2. Moreover, given that the neutralization observed after the first and the second booster dose was equivalent, we hypothesize that the neutralizing response against SARS-CoV-2 induced by the administration of the first booster dose of CoronaVac® has reached a peak of neutralizing antibodies that are sustained by the administration of a second booster dose.

The administration of the second booster dose of CoronaVac® kept the seropositivity rate higher than 96% for both sVNT and cVNT, with seroconversion levels of 93.1% and 95.2% for sVNT and cVNT, respectively (supplementary table 3).

Next, we evaluated whether the neutralizing antibodies generated after the second booster dose was effective against the Delta (B.1.617.2) and the Omicron (B.1.1.529) variants. Although serum from vaccinated individuals collected four weeks after the second booster dose presented a mildly reduced ability to neutralize WT SARS-CoV-2 when compared with samples collected four weeks after the first booster dose (Fig 2C), the neutralization response against WT SARS-CoV-2 was significantly higher when compared with the Delta (B.1.617.2) and especially with the Omicron (B.1.1.529) variants (33.0 vs. 3.7 GMTs $p<0.001$, 8.9-fold reduction) (Fig 2C, supplementary table 2). Moreover, as compared with the first booster dose, the administration of the second booster dose of CoronaVac® did not significantly impact the seropositivity rate (93.1% vs. 94.3%) and the seroconversion rate (80.5% vs. 67.8%) against the Delta variant, although it slightly increased the seropositivity rate (17.2% vs. 32.2%) and the seroconversion rate (4.6% vs. 18.4%) against the Omicron variant (supplementary table 4).

Neutralization against the Omicron variant was also confirmed with a pseudotype-based neutralization assay in sixty subjects (supplementary figure 1) and indicate that a second booster dose of CoronaVac® maintains high neutralizing antibody levels against WT SARS-CoV-2 that reduced neutralization capacity against the Omicron variant.

3. Cellular response against SARS-CoV-2 induced by a second booster dose of CoronaVac®.

We next evaluated the cellular response in a subgroup of fully vaccinated volunteers (n=46) that received two booster doses of CoronaVac® (Fig 1A). PBMCs were stimulated with mega-pools of peptides of SARS-CoV-2 theoretically able to activate $CD4^+$ T cells (S+R) and $CD8^+$ T cells (CD8A+B)[22] and SARS-CoV-2-specific $OX40^+CD137^+CD4^+$T cells (AIM^+CD4^+ T cells), as well as SARS-CoV-2 specific $CD69^+CD137^+CD8^+$ T cells (AIM^+CD8^+ T cells) were quantified by flow cytometry.

Our data show that the activation of SARS-CoV-2-specific AIM^+CD4^+ T cells was higher after the second dose of CoronaVac® in comparison with the pre-immune sample (0.13% vs. 0.33% p=0.0241) (Fig. 3A; supplementary table 5). Although no significant increase in the percentage of AIM^+CD4^+ T cells was observed after the administration of the first or the second booster dose, the activation of AIM^+CD4^+ T cells remained stable over time, showing only a significant decrease 4-6 months after the first booster dose, that is successfully recovered after the administration of the second booster dose (Fig 3A, supplementary table 5). Further, we did not detect a significant activation of SARS-CoV-2-specific AIM^+CD8^+ T cells in fully vaccinated

211 volunteers with CoronaVac® after the administration of the first or the second booster
212 dose (Fig. 3B; supplementary table 5).
213 Next, we evaluated the production of IFN-γ in stimulated-PBMCs by ELISPOT (Fig.
214 3C-D, supplementary table 5). The production of IFN-γ by stimulated PBMCs was
215 consistent with the activation of $CD4^+$ and $CD8^+$ T cells in subjects that received a
216 second booster dose of CoronaVac®. A significant increase in IFN-γ^+ SFCs was
217 observed in PBMCs stimulated with MP-S+R after the second dose of CoronaVac®
218 (4.1-fold increase in PBMCs stimulated with MP-S+R p=0.0004) (Fig 3C,
219 supplementary table 5). Moreover, the increase in IFN-γ^+SFCs observed after the
220 second dose of CoronaVac® remained stable over time and was also observed after
221 the administration of the first and the second booster dose (Fig 3C, supplementary
222 table 5). In contrast, no significant changes in IFN-γ^+SFCs were observed in PBMCs
223 stimulated with MP-CD8A+B after the second dose of CoronaVac® (1.5-fold increase
224 in PBMCs stimulated with MP-CD8A+B p>0.05) (Fig. 3D) nor after the administration
225 of a first or second booster of CoronaVac® (Fig 3D, supplementary table 5).
226 Even though we did not detect a significant increase in the frequency of AIM^+CD4^+T
227 cells after the administration of the first or the second booster doses of CoronaVac®,
228 we observed important changes in the frequency of volunteers with detectable levels
229 of AIM^+CD4^+T cells over time. Whereas 13.0% (6/46) of volunteers presented
230 detectable levels of SARS-CoV-2-specific AIM^+CD4^+T cells before vaccination, two
231 doses of CoronaVac® increased this frequency to 34.8% (16/46), frequency that was
232 further increased after the first booster of CoronaVac®, where 65.2% (30/46) of
233 subjects showed detectable levels of SARS-CoV-2-specific AIM^+CD4^+T cells (Table
234 1). Consistently, the frequency of subjects whose PBMCs produced IFN-γ after

stimulation with MP-S+R increased after the administration of CoronaVac®, starting from 17.4% (8/46) before vaccination to 47.8% (22/46) after two doses of CoronaVac® and to 67.4% (31/46) after the first booster of CoronaVac® (Table 1). Interestingly, the second booster of CoronaVac® (45.7%, 21/46) did not increase the frequency of volunteers that have specific SARS-CoV-2 specific AIM^+CD4^+T cells in circulation as compared with the first booster dose, although it seems that it is required to prevent the decrease in frequency of volunteers with SARS-CoV-2 specific AIM^+CD4^+T cells observed right before the administration of the second booster dose (41.3%, 19/46) (Table 1). Moreover, the second booster of CoronaVac® did not significantly affect the progressive decrease of IFN-γ production by stimulated PMBCs (50% 23/46) in comparison with the response induced by the first booster dose, where 67.4% of the volunteers (31/46) showed production IFN-γ production (Table 1).

A mild increase in the frequency of volunteers that showed AIM^+CD8^+ T cells after two doses of CoronaVac® (34.8%, 16/46) was observed as compared to before vaccination (13.0%, 6/46) (Table 1). Even though the administration of a first booster of CoronaVac® (34.8%, 16/46) was necessary to keep the frequency of volunteers with detectable levels of SARS-CoV-2-specific AIM^+CD8^+ T cells, the second booster dose (26.1%, 12/46) did not prevent the reduction of the positivity of SARS-CoV-2-specific AIM^+CD8^+ T cells in our cohort (Table 1). In addition, when PBMCs were stimulated with MP-CD8A+B, the frequency of volunteers that showed IFN-γ production reached a peak of 17.4% (8/46) right before the administration of a second booster that slightly decreased after the administration of the second booster dose of CoronaVac® (13.0%, 6/46) (Table 1).

Finally, we evaluated the activation of AIM^+CD4^+ T cells and IFN-γ^+ production by PBMCs in response to a mega-pool of peptides derived from the Spike protein of the Delta and the Omicron variants by flow cytometry and ELISPOT, respectively, four weeks after the administration of the first booster dose and four weeks after the administration of the second booster dose. Our data show that the activation AIM^+CD4^+ T cells and IFN-γ^+SFCs were equivalent when PBMCs were stimulated with a mega-pool of peptides derived from the WT SARS-CoV-2, the Delta, or the Omicron variants (Fig. 3E-F) and no major differences were detected in the activation of AIM^+CD4^+ T cells and IFN-γ^+SFCs in PBMCs, between the first and the second booster dose against each of these variants (Fig. 3E-F). Importantly, we detected a small decrease in the percentage of subjects that presented Spike-specific $CD4^+AIM^+$ against the WT, Delta and Omicron variants after the second booster compared with after the first booster dose (supplementary table 6). Importantly, the frequency of volunteers whose PBMCs produced IFN-γ remained constant after the stimulation of MP-S from WT and the Delta variant and only showed a mild decreased after MP-S from the Omicron variant (supplementary table 6).

These data show that CoronaVac® induces a robust $CD4^+$ T cells response able to react against the Delta and the Omicron variants that remains high after a second booster dose even though it showed a progressive decrease in its positivity. Although the humoral immunity against Delta and Omicron variants decreases, cellular immunity remains robust across time and reacts against these variants.

Discussion.

In line with other reports[4,19], our data show that a second booster dose of CoronaVac® restores the neutralizing response against the RBD of SARS-CoV-2 to similar levels reached after the administration of the first booster dose.

Neutralizing antibodies induced by vaccines has been acknowledged as the first line of defense against SARS-CoV-2 infection. However, follow-up studies have shown that fully vaccinated individuals show a gradual decrease in their levels of circulating neutralizing antibodies over time[14-16,18]. This response can be restored with the administration of a booster dose[14,18], and some studies have even shown that a second booster dose may grant better protection against severe disease, hospitalization, and death due to COVID-19[4,23].

Our data show that despite a second booster dose induces the production of neutralizing antibodies against WT SARS-CoV-2, these antibodies only weakly neutralized the Omicron variant. These results are consistent with other studies that show that the Omicron variant and its subvariants are incredibly efficient in evading serum neutralization from individuals who have received one or two booster doses[1,19,24]. Therefore, it is unlikely that nowadays, the increased protection against severe disease, hospitalization, and death granted by a second booster dose could be mainly mediated by the action of neutralizing antibodies.

Nonetheless, we detected a slight but non-significant increment of 1.6-fold change in the neutralization of WT SARS-CoV-2 between four weeks after the first booster dose and four weeks after the second booster dose by cVNT (Fig 1B). This modest increase in WT SARS-CoV-2 neutralization granted by the second booster was not observed through sVNT (Fig 1A, C). sVNT directly neutralizes the binding of the RBD with ACE-2, neglecting the potential role of neutralizing antibodies against other

307 portions of the Spike protein and even against other viral proteins. Therefore, it is
308 possible that neutralizing antibodies against other domains of the Spike protein and
309 potentially against other viral proteins such as the membrane or the nucleocapsid
310 proteins not considered in the sVNT approach may actively participate in viral
311 neutralization.

312 The second layer of protection corresponds to the proliferation, activation, and
313 activity of T cells. Currently, the leading hypothesis regarding the protective
314 mechanism of SARS-CoV-2 vaccines against severe disease and death relies on
315 the induction of long-lasting T cells responses rather than on the availability of
316 circulating neutralizing antibodies[25,26].

317 In the present study, we report that the activation of AIM^+CD4^+ T cells in fully
318 vaccinated individuals remains detectable over time after administering a first and a
319 second booster of CoronaVac®. In addition, one study has identified a robust
320 activation of $CD4^+OX40^+CD137^+$ T cells, $CD4^+OX40^+sCD40L^+$ T cells, and follicular
321 $CD4^+CXCR5^+OX40^+$ T cells in individuals that received two doses of mRNA-1273,
322 BNT162b2 or NVX-CoV2373 (Novavax), and one dose of Ad26.COV2.S
323 (Janssen)[27]. Our data is consistent with these findings, although the ability of
324 CoronaVac® to induce a robust memory T cell response remains to be elucidated.

325 On the other hand, it has been reported a significant expansion and activation of
326 IFN-γ^+CD8^+ T cells in PBMCs of individuals vaccinated with two doses of mRNA-
327 1273, BNT162b2, and NVX-CoV2373, and one dose of Ad26.COV2.S[27]. However,
328 we did not find a significant increase in $CD8^+AIM^+$ T cells (Fig. 3B) nor a significant
329 increase in IFN-γ production (Fig 3D) in stimulated PBMCs from subjects immunized
330 with CoronaVac® when compared with the pre-immune sample. In contrast, previous

331 studies have described that two doses of CoronaVac® induce the production of IFN-
332 γ by $CD8^+$ T cells[28,29]. Therefore, more exhaustive studies aimed to understand how
333 CoronaVac® influences the expansion and activation of $CD8^+$ T cells, memory T
334 cells, and memory B cells are required to fully elucidate the protective mechanisms
335 driven by CoronaVac® in immunized adults, children, and the elderly.
336 Four interesting findings emerge from our study. First is the presence of neutralizing
337 antibodies (Fig 2A-B) in pre-immune samples of some individuals. Most of the pre-
338 immune neutralizing response was identified against the infective virus.
339 Asymptomatic SARS-CoV-2 infections[30] and antibodies generated against non-
340 spike proteins of seasonal coronaviruses[31] could explain this response, although
341 serologic studies are needed to confirm these hypotheses. Moreover, our data show
342 that whereas 6/46 of the analyzed volunteers presented SARS-CoV-2-specific
343 AIM^+CD4^+ or AIM^+CD8^+ T cells before the administration of CoronaVac®; 25/46 and
344 34/46 volunteers did not present AIM^+CD4^+ or AIM^+CD8^+ T cells, respectively after
345 the second booster of CoronaVac®. A previous study has shown a possible cross-
346 reactive response of seasonal coronaviruses-specific T cells against SARS-CoV-2[22],
347 and it is likely the reason why some volunteers presented SARS-CoV-2 specific T
348 cells before vaccination, although asymptomatic infections cannot be ruled out.
349 Further studies are needed to fully understand the factors involved in the generation
350 and maintain of an efficient T cell response and the effect on vaccine-induced
351 protection.
352 Finally, our data show that the effect on humoral and cellular responses of the
353 second booster dose, is different when compared with the effect of the first booster
354 dose. Whereas our data and several other studies have shown that a first booster

355 increase the humoral and cellular response against SARS-CoV-2[14,15,17,18], the
356 administration of a second booster dose seems to maintain the global neutralizing
357 response, the activation of AIM^+CD4^+ T cells and IFN-γ by stimulated PBMCs
358 against WT SARS-CoV-2 and the Omicron variant reached by the first booster dose.
359 Importantly, in terms of the percentage of individuals able to respond against the
360 virus, our data show that even though the second booster restores seropositivity and
361 seroconversion to equivalent levels observed after the first booster dose, it seems
362 to be insufficient to restore the frequency of volunteers with detectable SARS-CoV-
363 2-specific AIM^+CD4^+ T cells and IFN-γ by stimulated PBMCs to levels observed after
364 the first booster dose.
365 Controlling the COVID-19 pandemic requires multiple efforts to prevent severe
366 disease and death of infected patients and reduce viral infection and circulation in
367 the community.
368 The data provided in this report and other studies suggest that CoronaVac® and
369 other current vaccines effectively protect the population from severe disease,
370 hospitalization, and death. However, the immune response induced by these
371 vaccines poorly neutralizes the circulating SARS-CoV-2 variants and cannot prevent
372 viral infection.
373 Therefore, new strategies that include the design of new vaccines that target the
374 current variants, new types of vaccines that enforce immunity in the upper respiratory
375 tract, and global vaccine distribution programs are essential to control and end the
376 COVID-19 pandemic.

Methods.

Volunteers and sample collection

Blood samples were obtained from volunteers recruited in the clinical trial CoronaVac03CL (clinicaltrials.gov #NCT04651790) in Chile (November 2020- to current date)[12,13,18,20,21].

Of the 2,302 individuals enrolled at baseline, 409 subjects entered the study and received two doses with the homologous CoronaVac® 0-28 schedule, and 138 subjects ended up receiving two booster doses of CoronaVac®. In addition, blood samples from 87 subjects were collected from before vaccination (T0) to up to four-nine weeks after the second booster administration (T6). Volunteers who did not have a blood sample at some of the planned times of the study or who had previously exceeded the definitive time limit and volunteers who had developed SARS-COV-2 during the study were excluded (Figure 1A).

Volunteers received two doses of CoronaVac® (3 µg or 600SU of inactivated SARS-CoV-2 inactivated in the presence of alum adjuvant) in a four-week interval (0-28 days), a booster dose five months after the second dose, and a second booster dose 6 months after the first (Figure 1B). Blood samples collected 6 times were analyzed: T1: Pre-immune, T2: 2nd dose + 4 weeks (+3 weeks), T3: before the administration of the third dose (-9 weeks), T4: at 4 weeks (±2 weeks) after the third dose, T5: before the administration of the fourth dose (-9 weeks), T6: and at 4 weeks (+5 weeks) after the fourth dose (T6), and vaccination schedule.

Experimental procedures

Neutralizing antibodies against RBD of WT SARS-CoV-2 were measured in the serum of 87 volunteers recruited in the clinical trial CoronaVac03CL (clinicaltrials.gov #NCT04651790). Briefly, blood samples were obtained at T1, T2, T3, T4, T5, and T6. Neutralization of SARS-CoV-2 RBD by circulating antibodies at each time point was evaluated by a surrogate virus neutralization test (sVNT) (Genscript Cat#L00847-A)[12]. The antibody levels in international units per mL (IU/mL) were estimated by interpolating the sVNT absorbance data in the standard curve made with the WHO International Standard 20/136, using the 4-parameter Logistic model. In addition, sVNT was used to evaluate the neutralizing capacity of the tools against the Delta and Omicron variants, the RBDs for the S protein of SARS-CoV-2 for Delta (Cat# Z03516) and Omicron B.1.1.529 (Cat#Z03730) in 87 volunteers.

Infective virus neutralization assays were performed as previously described[12,18]. Briefly, Vero E6 cells (4×10^4 cells/well) were plated in 96-well plates. 100 µL of 33782CL-SARS-CoV-2 (100 $TCID_{50}$) were incubated with serial dilutions of heat-inactivated individual serum samples (dilutions of 1:4, 1:8, 1:16, 1:32, 1:64, 1:128, 1:256, and 1:512) for 1h at 37 °C. Then, the mix was added to the 96-well plates with the Vero E6 cells, and the cytopathic effect was analyzed after 7 days. A serum sample from uninfected patients (negative control) and a neutralizing COVID-19 patient serum sample (positive control) was used for each test.

A pseudotyped virus neutralization test (pVNT) assay was performed to assess the capacity of the antibodies against SARS-CoV-2 VOC in samples from forty-eight volunteers as previously reported[32]. Briefly, a HIV-1 backbone expressing firefly luciferase as a reporter gene and pseudotyped with the SARS-CoV-2 spike glycoproteins (HIV-1-SΔ19) from lineage B.1 (D614G) and variant Omicron (A67V,

ΔH69-V70, T95I, Y145D, ΔG142 -V143- Y144, ΔN211, EPE 213-214, G339D, S371L, S373P, S375F, K417N, N440K, G446S, S477N, T478K, E484A, Q493R, G496S, Q498R, N501Y, T547K, D614G, H655Y, N679K, P681H, N764K, N865K, Q954H, N969K, L981F) was prepared. Serum samples were diluted, and the estimation of the ID80 was obtained using a 4-parameter nonlinear regression curve fit measured as the percent of neutralization determined by the difference in average relative light units (RLU) between test samples and pseudotyped virus controls. Seropositivity is considered when titers are increased compared to pre-immune condition[33]. On the other hand, seroconversion was thought to be when the titer of neutralizing results increased 4 times with respect to the pre-immune condition.

The expression of Activation-Induced Markers (AIM) by T cells and the number of Spot Forming Cells (SFC) for IFN-γ were determined by ELISPOT and were evaluated by flow cytometry in a subgroup of 46 volunteers as previously described[12,13,18]. Briefly, PBMCs were stimulated with mega-pools (MPs) of peptides derived from SARS-CoV-2: MP-S, MP-R, MP-CD8-A, MP-CD8-B, Delta, and Omicron for 24h or 48h for flow cytometry and ELISPOT respectively. Then, 3-5 x 10^5 cells were plated and stimulated with MP-S, MP-R, MP-CD8A, MP-CD8B, DMSO (negative control), or Phorbol-12-acetate (1.62mM) (Sigma, #P8139)/Ionomycin (0.6mM) (Sigma #I0634)[22]. Antibodies used to identify AIM^+CD4^+, and AIM^+CD8^+ T cells by flow cytometry are detailed in supplementary table 7. Samples were analyzed in a BD LSR-FORTESSA flow cytometer located in the flow cytometry core at the Pontificia Universidad Católica de Chile. For AIM^+CD4^+, and AIM^+CD8^+ T cells analyses, the percentage of DMSO was subtracted from each stimulated sample to subtract the background. The positivity threshold for

448 AIM^+CD4^+ T cell stimulated with MP-S (0.174%) and MP-S+R (0.36%), as well as
449 AIM^+CD8^+ T cell stimulated with MP-CD8A+B (0.66%) was calculated using the
450 median twofold standard deviation of each sample of the pre-immune group[22,34].
451 For ELISPOT, IFN-γ was measured using a Immunospot® (#hIFNgIL-4M-10)
452 following the manufacturer's instructions. Plates were read in an Immunospot S6
453 Micro Analyzer. The positivity threshold for PBMCs stimulated with MP-S (19.31
454 #SFC) MP-S+R (41.48 #SFC), as well as PBMCs stimulated with MP-CD8A+B
455 (104.54 #SFC) was calculated using the median twofold standard deviation of each
456 sample of the pre-immune group.
457
458 Ethical considerations.
459 The current study protocol was reviewed and approved by the Institutional Scientific
460 Ethical Committee of Health Sciences at the Pontificia Universidad Católica de Chile
461 (#200708006) and the trial was approved by the Chilean Public Health Institute
462 (#24204/20) and conducted according to the current Tripartite Guidelines for Good
463 Clinical Practices, the Declaration of Helsinki, and local regulations. Informed
464 consent was obtained from all volunteers upon enrollment.
465
466 Statistical analyses
467 To statistically compare the neutralizing response against WT SARS-CoV-2,
468 ANOVA with the Geisser-Greenhouse correction test followed by Sidak multiple tests
469 were carried out on the log transformed data. Percentage of AIM^+CD4^+ and
470 AIM^+CD8^+ T cells and IFN-γ production by stimulated PBMCs against WT SARS-

CoV-2 were compared with a non-parametric Friedman test followed by a Dunn's test for multiple comparisons. To compare the neutralizing and the cellular responses against WT, Delta and Omicron, a two-way ANOVA test followed by a Dunn's test for multiple comparisons was used.

The significance level was set at 0.05 for all the analyses. All data were analyzed with GraphPad Prism 9.3.1.

Funding

The CoronaVac03CL Study was funded by The Ministry of Health, Government of Chile, the Confederation of Production and Commerce (CPC), Chile and SINOVAC Biotech. NIH NIAID, under Contract 75N93021C00016, supports AS and Contract 75N9301900065 supports AS, AG and DW. The Millennium Institute on Immunology and Immunotherapy, **Agencia Nacional de Investigación y Desarrollo (ANID) – Millennium Science Initiative Program – ICN09_016 / ICN 2021_045: Millennium Institute on Immunology and Immunotherapy (ICN09_016 / ICN 2021_045; former P09/016-F)** supports SMB, KA, PAG and AMK; The Innovation Fund for Competitiveness FIC-R 2017 (BIP Code: 30488811-0) supports SMB, PAG and AMK.

Competing interests

GZ and WM are SINOVAC Biotech employees and contributed to the conceptualization of the study (clinical protocol and eCRF design) and did not participate in the analysis or interpretation of the data presented in the manuscript. A.S. is a consultant for Gritstone Bio, Flow Pharma, ImmunoScape, Moderna,

AstraZeneca, Avalia, Fortress, Repertoire, Gilead, Gerson Lehrman Group, RiverVest, MedaCorp, and Guggenheim. La Jolla Institute for Immunology (LJI) has filed for patent protection for various aspects of T cell epitope and vaccine design work. All other authors declare no conflict of interest.

Acknowledgments

We would like to thank the support of the Ministry of Health, Government of Chile; Ministry of Science, Technology, Knowledge, and Innovation, Government of Chile; The Ministry of Foreign Affairs, Government of Chile, and the Chilean Public Health Institute (ISP). We also would like to thank Rami Scharf, Jessica White, Jorge Flores and Miren Iturriza-Gomara from PATH for their active support in experimental design and scientific discussion. We also thank the Vice Presidency of Research (VRI), the Direction of Technology Transfer and Development (DTD) and the Legal Affairs Department (DAJ) of the Pontificia Universidad Católica de Chile. We are grateful to the Administrative Directions of the School of Biological Sciences and the School of Medicine of the Pontificia Universidad Católica de Chile for their administrative support. We would also like to thank to the members of the independent data safety monitoring committee (members in the SA) for their oversight, and finally to the subjects enrolled in the study for their participation and commitment with this trial. This project has been funded in whole or in part with Federal funds from the National Institute of Allergy and Infectious Diseases, National Institutes of Health, Department of Health and Human Services, under Contract No. 75N93021C00016 to A.S. and Contract No. 75N93019C00065 to A.S and D.W.

681

682 **Figure 1. Study profile, vaccination scheme and sampling, enrolled volunteers,**
683 **and cohort included in the study.** (A) Schematic representation and sample
684 distribution of performed experiments. From a total of 138 individuals that received
685 two booster doses of CoronaVac®, the neutralizing antibodies were analyzed in
686 blood samples from 87 volunteers by surrogate virus neutralization test (sVNT), 63
687 by conventional virus neutralization test (cVNT) and 60 by Pseudovirus-based
688 neutralization assay (pVNT). sVNT and pVNT were used to evaluate the neutralizing
689 response induced by a second booster dose against the Delta and/or the Omicron
690 variants. Cellular immunity was analyzed in blood samples from 46 volunteers at
691 each time point. (B) Blood sampling times, before the first vaccination/pre-immune
692 (T1), at 4 weeks (+3 weeks) after the second dose (T2), before the administration of
693 the third dose (-9 weeks) (T3), at 4 weeks (-1/+2 weeks) after the third dose (T4),
694 before the administration of the fourth dose (-9 weeks) (T5) and at 4 weeks (+5
695 weeks) after the fourth dose (T6), and vaccination schedule.

696

697 **Figure 2. Humoral response of volunteers who received a second booster dose**
698 **of CoronaVac®.** The neutralizing capacity of circulating antibodies in adults was
699 evaluated in Blood samples collected before the first vaccination/pre-immune (T1),
700 at 4 weeks (+3 weeks) after the second dose (T2), before the administration of the
701 third dose (-9 weeks) (T3), at 4 weeks (-1/+2 weeks) after the third dose (T4), before
702 the administration of the fourth dose (-9 weeks) (T5) and at 4 weeks (+5 weeks) after
703 the fourth dose (T6), and vaccination schedule. (A) Neutralizing capacity of

704 circulating antibodies against SARS-CoV-2 in serum of 87 volunteers was
705 determined by a surrogate Viral Neutralization Test (sVNT) expressed as IU/ml. (B)
706 Reciprocal dilution of sera required to prevent in vitro infection obtained sera from
707 63 adults required to prevent in vitro infection of Hela Cells. Numbers on top of each
708 data set represents the GMT, and horizontal lines represent the 95% CI. (C)
709 Geometric mean titter (GMTs) of neutralizing antibodies against the WT-spike, Delta-
710 spike and Omicron-spike proteins detected in the serum of 87 volunteers immunized
711 with CoronaVac® through sVNT. Dashed line: limit of detection. Red values under
712 the significance line: indicate a decrease in the means of the two compared time
713 points; Blue values: indicate an increase in the means of the two compared time
714 points. (A-B) Data was analyzed with ANOVA with the Geisser-Greenhouse
715 correction test followed by a post-hoc Sidak multiple test. *P<0.05; **P<0.01;
716 ***P<0.001; ****P<0.0001. (C) Two-way ANOVA test followed by a post-hoc Dunn's
717 multiple test. *P<0.05; **P<0.01; ***P<0.001, ****P<0.0001.
718
719 **Figure 3. Cellular response of volunteers that received a second booster dose**
720 **of CoronaVac®.** Cellular response in adults was evaluated in PBMCs collected
721 before the first vaccination/pre-immune (T1), at 4 weeks (+3 weeks) after the second
722 dose (T2), before the administration of the third dose (-9 weeks) (T3), at 4 weeks (-
723 1/+2 weeks) after the third dose (T4), before the administration of the fourth dose (-
724 9 weeks) (T5) and at 4 weeks (+5 weeks) after the fourth dose (T6), and vaccination
725 schedule. (A) The percentage of AIM+ (OX40+CD137+) CD4+ T cells and (B) AIM+
726 (CD69+CD137+) CD8+ T cells was determined in PBMCs of 46 adult volunteers by
727 flow cytometry. PBMCs were stimulated for 24h with mega-pools of peptides derived

from proteins of WT SARS-CoV-2. The number of IFN-g producing SFCs was determined by ELISPOT upon stimulation for 48h with mega-pools of (C) S+R peptides or with (D) CD8A+B peptides. (E) The percentage of AIM+ (OX40+CD137+) CD4+ T cells from PBMCs of 46 adult volunteers were analyzed by flow cytometry after the stimulation for 24h with mega-pools of peptides derived from the Spike protein of the WT SARS-CoV-2, the Delta and the Omicron variants. (F) The number of IFN-g producing SFCs was determined by ELISPOT assays PBMCs of 46 adult volunteers were analyzed by flow cytometry after the stimulation for 48h with mega-pools of peptides derived from the Spike protein of the WT SARS-CoV-2, the Delta and the Omicron variants. Horizontal lines represent mean and 95% CI. Flow cytometry data was normalized against the DMSO control. (A-D) Data was analyzed using a non-parametric Friedman test followed by a post-hoc Dunn's test for multiple comparisons. *P<0.05; **P<0.01; ***P<0.001; ****P<0.0001. (E-F) Two-way ANOVA test followed by a post-hoc Dunn's multiple test. *P<0.05; **P<0.01; ***P<0.001, ****P<0.0001.

A

Total enrolled individuals (**N = 2,302**)

Volunteers that received two doses of CoronaVac® in a 0-14 and 0-28 schedule **(N=2,263)**

Fully vaccinated volunteers (0-28 schedule) that received two booster doses of CoronaVac® (**N=409**)

Volunteers of the immunogenicity branch (**N=142**)

Fully vaccinated volunteers that received two booster doses of CoronaVac® followed up to 4 weeks **(N=138)**

Excluded volunteers due to **(N=51)**
- SARS-COV-2 breakthrough cases
- One o more missing visits

Humoral immunity

- sVNT analysis (**N=87**)
- cVNT analysis (**N=63**)
- sVNT analysis for the Delta and the Omicron variants (**N=87**)
- pVNT analysis for the Omicron variant (**N=60**)

Cellular immunity

- ELISPOT and Flow cytometry analyses (**n=46**)
- ELISPOT and Flow cytometry against the Delta and the Omicron variants (**n=46**)
