15 **ABSTRACT**

16 **Objective** Senegal has demonstrated catalytic improvements in national coverage rates for early
17 childhood vaccination, despite lower development assistance for childhood vaccines in Senegal compared
18 to other low and lower-middle income countries. Understanding factors associated with historical changes
19 in childhood vaccine coverage in Senegal, as well as heterogeneities across its 14 regions, can highlight
20 effective practices that might be adapted to improve vaccine coverage elsewhere.

21 **Design** Childhood vaccination coverage rates, demographic information, and health system characteristics
22 were identified from Senegal's Demographic and Health Surveys (DHS) and Senegal national reports for
23 years 2005 to 2019. Multivariate logistic and linear regression analyses were performed to determine
24 statistical associations of demographic and health system characteristics with respect to childhood
25 vaccination coverage rates.

26 **Setting** The 14 administrative regions of Senegal were chosen for analysis.

27 **Participants** DHS women's survey respondents with living children aged 12-23 months for survey years
28 2005-2019.

29 **Outcome Measures** Immunization with the third dose of the diphtheria-tetanus-pertussis vaccine (DTP3),
30 widely used as a proxy for estimating immunization coverage levels and the retention of children in the
31 vaccine program.

32 **Results** Factors associated with childhood vaccination coverage include urban residence ($\beta=0.61$,
33 $p=0.0157$), female literacy ($\beta=1.11$, $p=0.0007$), skilled prenatal care ($\beta=1.80$, $p<0.0001$), and self-
34 reported ease of access to care when sick, considering travel distance to a healthcare facility ($\beta=-0.70$,
35 $p=0.0009$) and concerns over traveling alone ($\beta=-1.08$, $p<0.0001$). Higher coverage with less variability
36 over time was reported in urban areas near the capital and the coast ($p=0.076$), with increased coverage in
37 recent years in more rural and landlocked areas.

38 **Conclusions** Childhood vaccination was more likely among children whose mothers had higher literacy,
39 received skilled prenatal care, and had perceived ease of access to care when sick. Overall, vaccination
40 coverage is high in Senegal and disparities in coverage between regions have decreased significantly in
41 recent years.

42

43 **Background**

44 Vaccination is one of the most cost-effective and influential public health interventions [1]. For each
45 dollar spent on routine and supplementary vaccinations in low- and middle-income countries from 2011-
46 2020, the average country-level return on investment is estimated to be 44 times the cost [2]. High
47 vaccination coverage is necessary for controlling, eliminating, or eradicating vaccine-preventable diseases
48 [3]. Gavi, The Vaccine Alliance (Gavi), was launched in 2000 and is one of the main sources of vaccine
49 financing for eligible low- and middle-income countries. Some but not all Gavi-supported countries were
50 able to reach the 2015 Global Vaccine Action Plan (GVAP) goal of 90% coverage for the third dose of
51 the diphtheria-tetanus-pertussis vaccine (DTP3) by 2010 [4, 5].

52 In 2017, Africa reported a DTP3 coverage of 72%, the lowest percentage of all the World Health
53 Organization (WHO) regions [4]. Within the African Region, several countries have outperformed their
54 peers with regards to high and sustained vaccination coverage. DTP3 coverage in Senegal increased from
55 52% to 93% [6], outperforming other low income (LIC) and lower-middle income (LMIC) countries,
56 despite lower development assistance for health (DAH) relative to many other countries in this group [7,
57 8], . The Government of Senegal has demonstrated a commitment to improving access to health care,
58 including childhood vaccination, which likely contributed to the country's success [9-11]. However, like
59 other countries in sub-Saharan Africa, Senegal's childhood vaccine coverage was not consistent between
60 Senegal's 14 administrative regions

61 The purpose of this study was to identify factors associated with DTP3 coverage in Senegal at both the
62 household level and regionally. DTP3 is often used as a proxy for estimating the retention of children in
63 the vaccine program [3]. Subnational trends in early childhood vaccine coverage often illustrate inequities
64 in vaccine service delivery [12, 13], and looking at national-level data alone may overestimate vaccine
65 system performance [14]. Factors statistically associated with full childhood immunization coverage have
66 been identified in previous studies [15-18]. We complement prior work by focusing on DTP3 coverage in
67 Senegal, with an analysis of changes in coverage over time by administrative region from 2005-2019. We
68 analyzed geographic and population factors, including female literacy and access to skilled prenatal care.
69 We also considered factors aggregated at the regional level including poverty and the number of
70 healthcare workers.

71 **Methods**

72 We conducted a study to assess the demographic associations of early childhood vaccination within
73 Senegal, including assessing the impact of heterogeneities at the subnational level (i.e., between
74 administration regions). For the study period of 2005-2019, we analyzed geographic and population
75 factors for each of Senegal's 14 administrative regions to examine potential associations with DTP3
76 coverage. The analysis was conducted as part of the Vaccine Exemplars Program, the purpose of which
77 was to identify how and why some countries have achieved better-than-average and sustained coverage of
78 early childhood vaccines [11, 19-21].

79 **Data sources**

80 Household-level immunization data was collected from Senegal's Demographic and Health Surveys
81 (DHS) (years 2005, 2010/2011, 2012/2013, and yearly from 2014 to 2019) [22], with data provided for all
82 14 regions and all years (notably 3 of the regions were created/split from existing regions in 2008;
83 coverage for these regions in 2005 is estimated to be equal to that of the original combined regions). The
84 data can be accessed upon approval from the DHS Program [23]. DHS surveys were sampled to be

85 representative at the regional level, and thus we were not able to analyze statistical associations at the
86 smaller district level. 28 sampling strata are created which correspond to urban and rural parts for each of
87 the 14 regions; samples are drawn independently from these sampling strata. Specific details on sampling
88 methods for each survey year can be found in the appendices of each report (see [22]). Data extracted
89 from the surveys include DTP3 vaccination (recommended administration to children at 14-weeks-old in
90 Senegal), residence type (urban or rural), female literacy, proportion receiving prenatal care from skilled
91 providers, and self-reported problems accessing care when sick (i.e., women were asked if distance,
92 permission, money, and traveling alone were significant barriers when seeking treatment).

93 Child immunization is covered in the women's questionnaire in DHS surveys with responses representing
94 each child of the mother surveyed. Literacy is assessed in the survey by the questioner asking the
95 respondent to read from a card [24]. Prenatal (or antenatal) care is assessed by asking women who
96 attended their last birth, with the following options: doctor, nurse/midwife, auxiliary nurse/midwife,
97 community health worker, other health worker, traditional birth attendant, other, and no antenatal care.

98 Region-specific population density and poverty (reported for year 2018) were determined from Senegal
99 national reports [25]. Poverty incidence is estimated using the cost of basic needs approach, which
100 considers the proportion of the population unable to meet their basic needs and combines a country-
101 specific food poverty line and non-food poverty line. For more details with respect to this calculation
102 specific to Senegal, see [26]. We collected regional counts of skilled healthcare workers from the
103 Ministère de la Santé et de l'Action sociale (MSAS) (2018) [27].

104 **Data analysis**

105 Bivariate and multivariate logistic and linear regression analyses were performed to determine statistical
106 associations of factors with respect to coverage of DTP3; factors included in multivariate analysis include
107 residence type (urban or rural), female literacy, self-reported problems accessing care when sick, and
108 prenatal care provider. We calculated DTP3 coverage – the dependent variable in our models - for each

109 region of Senegal using DHS data for each year available during the study period. The immunization
110 coverage for a region was calculated as the percentage of living children ages 12-23 months represented
111 in the survey for that region who received DTP3. Data must be weighted because the overall probability
112 of a household being selected is not constant across regions and residence types [28]. Thus, we compute
113 the individual weight for women and households to adjust for differences in probability of selection and
114 response between cases in a sample. We filter the data for living children ages 12-23 months. For the
115 time series data, we do this for each year of data available. A vaccination is considered administered if it
116 is reported by the mother or marked on the vaccination card with or without a date.

117 For our analysis, we consider a woman to be literate if she is able to read a whole sentence or part of a
118 sentence as reported in the DHS survey [24, 28]. We consider a woman to have received skilled prenatal
119 care if she answered “doctor”, “nurse/midwife”, or “auxiliary nurse/midwife” as attending her most recent
120 birth.

121 We calculated the Pearson correlation coefficients (r) to determine statistically significant correlations
122 between the quantitative factors and between factors and DTP3 coverage. We clustered regions
123 geographically into 2 groups (coastal and inland), calculated the variance in DTP3 values over time for
124 each region, and performed independent sample t-tests to compare these two groups of variances.

125 **Patient and public involvement**

126 There was no patient or public involvement in the study design of this research, the interpretation of the
127 results, or the writing or editing of this document. All data used in this analysis was de-identified public
128 health data.

129

130 **Results**

131 Table 1 reports the number of DHS survey respondents (unweighted) in each survey data set which fit the
132 criteria for inclusion (i.e., with living children aged 12-23 months). The number of respondents in each
133 region per year is reported in Table S1 in the supplemental material.

SURVEY YEAR	RESPONDENTS FITTING CRITERIA
2005	2138
2010/2011	2377
2012/2013	1329
2014	2662
2015	1310
2016	1323
2017	2390
2018	1337
2019	1183

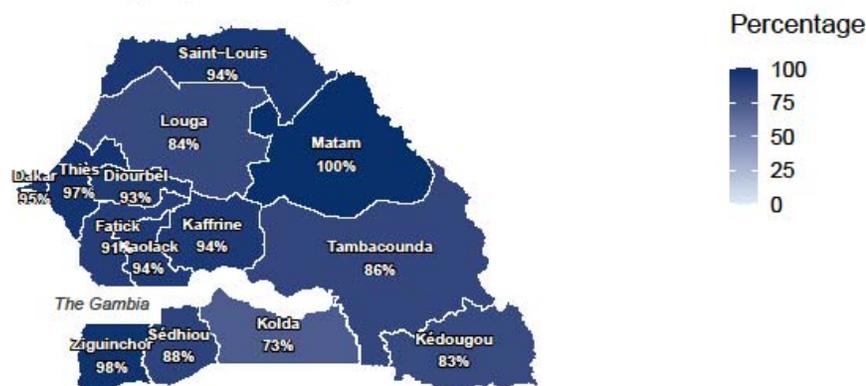

134

135 *Table 1 Senegal household survey data years and unweighted number of survey respondents meeting criteria for inclusion.*

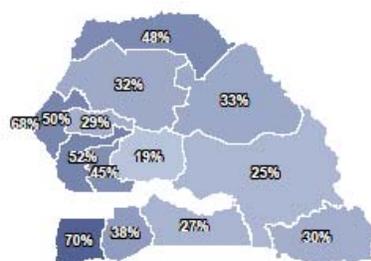

136 **Factors associated with DTP3 coverage by administrative region**

137 For each region in Senegal, Table S2 in the supplemental material reports the weighted percentage of
138 survey respondents with “yes” responses per household factor for year 2019; data is filtered for
139 respondents who meet inclusion criteria. DTP3 coverage by region ranged from 73% to 100% in 2019
140 (Figure 1, Table S2). Higher DTP3 coverage rates were observed in Dakar (the most populous region and
141 includes the capital city) and its surrounding regions, and along the coast, as well as in the landlocked
142 region of Matam. In 2018, there were approximately 6,600 people per km² in Dakar, which is
143 predominantly urban (97% urban) [29]. The population density in other regions was at most 362 people
144 per km². Population density does not have a statistically significant correlation with DTP3 coverage at the
145 regional level, though this correlation is higher when excluding Dakar (Pearson’s correlation $r=0.39$,
146 $p=0.19$).

(i) DTP3 coverage by region of Senegal (DHS 2019)

(ii) Female population considered literate

(iii) Received skilled prenatal care

(iv) Ease of access to care – Traveling alone

147

148 *Figure 1 DTP3 coverage by region of Senegal and regional proportions of select metrics [30]. “Skilled Prenatal Care” refers to the*
 149 *proportion of women ages 15-49 who had a live birth within 5 years before the survey who had prenatal care provided by a*
 150 *skilled health care worker (2017). Skilled care includes doctor, nurse, and midwife. Unskilled care includes matron/traditional*
 151 *midwife, “other”, or none. “Ease of Access to Care – Traveling Alone”, refers to the proportion of female survey respondents by*
 152 *region who did not consider traveling alone to be a significant problem with accessing care when sick (2017).*

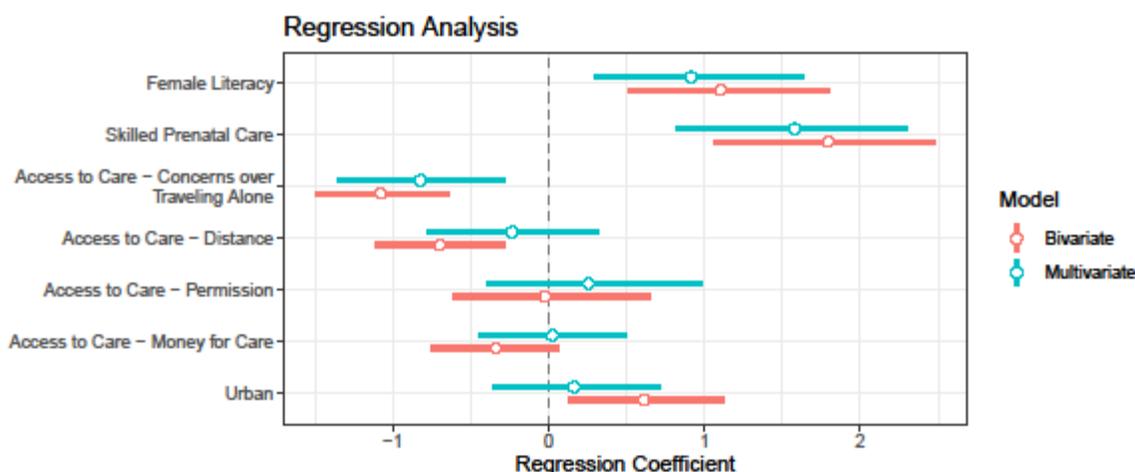

153 Unadjusted bivariate analyses (Figure 2) revealed significant associations ($p=0.05$) between higher DTP3
 154 vaccination and the following:

- 155 • positive associations:
 - 156 ○ type of place of residence (urban) ($\beta=0.61$, $p=0.0157$),
 - 157 ○ higher female literacy ($\beta=1.11$, $p=0.0007$),
 - 158 ○ higher skilled prenatal care ($\beta=1.80$, $p<0.0001$), and

- 159 • negative associations:
 - 160 ○ more barriers when seeking treatment with respect to
 - 161 ■ distance ($\beta=-0.70$, $p=0.0009$) and
 - 162 ■ traveling alone ($\beta=-1.08$, $p<0.0001$).

163 We find that significant associations hold for female literacy, skilled prenatal care, distance, and traveling
164 alone when adjusting by type of place of residence (urban).

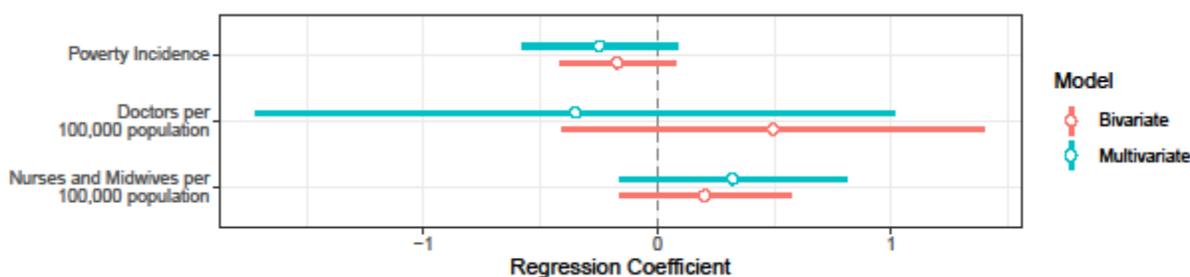

165 Multivariate regression revealed correlations between factors (Figure 2), with only 3 factors remaining
166 statistically significant: positive associations with female literacy ($\beta=0.92$, $p=0.0065$) and skilled prenatal
167 care ($\beta=1.58$, $p<0.0001$), and negative associations with more barriers when seeking treatment with
168 respect to traveling alone ($\beta=-0.82$, $p=0.0026$) (more details provided in Table S3 in the supplemental
169 materials). We also found correlations between population density and fewer barriers when seeking
170 treatment with respect to distance ($r=0.61$, $p=0.02$) and traveling alone ($r=0.48$, $p=0.08$); traveling alone is
171 correlated with distance ($r=0.51$, $p<0.0001$).

172
173 *Figure 2 Regression analysis for household-level factors associated with DTP3 vaccination by DHS 2019 survey response per*
174 *living child aged 12-23 months (weighted N=1129). The bars correspond to 95% confidence intervals. Bars which do not*
175 *intersect 0 correspond to statistical associations with DTP3 vaccination (< 0 implies negative association, > 0 implies positive*
176 *association).*

178 Coastal regions, namely, Dakar and Ziguinchor, have the highest female literacy rates (68% and 70%,
179 respectively). The percentage of women who received skilled prenatal care from a doctor, nurse, or
180 midwife was lowest in Tambacounda and Kedougou (88% and 85%, respectively), compared to over 95%
181 in other regions (Figure 1).

182 Poverty level did not statistically explain regional differences in DTP3 coverage (bivariate regression
183 coefficient $\beta = -0.17$, $p = 0.157$), potentially due to heterogeneity within regions. We also found no
184 statistical associations between DTP3 coverage and the number of doctors, nurses, and midwives per
185 100,000 population using bivariate or multivariate regression analysis (Figure 3, more details provided in
186 Table S4 in the supplemental materials).

187
188 *Figure 3 Regression analysis for region-level factor associations with DTP3 vaccination. Poverty incidence is estimated using the*
189 *cost of basic needs approach, which considers the proportion of the population unable to meet their basic needs and combines a*
190 *country-specific food poverty line and non-food poverty line [26]. The bars correspond to 95% confidence intervals.*

191

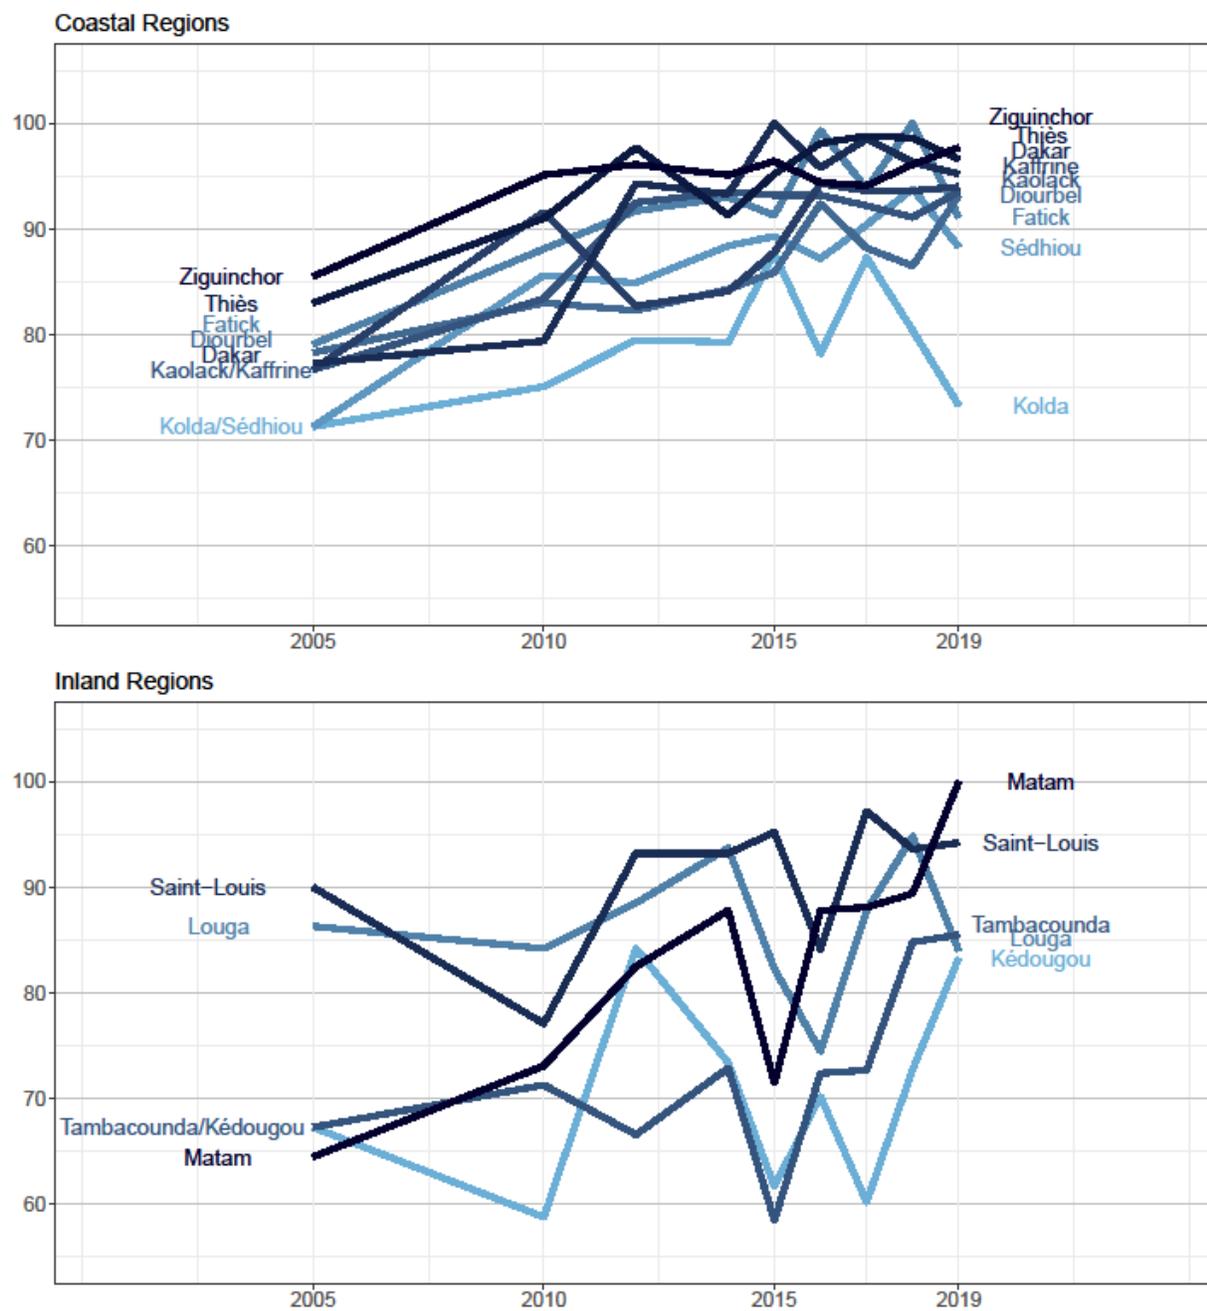

192 Access to Health Services

193 Women in regions with low DTP3 coverage reported more barriers to accessing care with respect to (i)
194 traveling alone to seek care and (ii) distance from healthcare facilities. In the more remote, inland regions
195 of Senegal, as many as 42% of female respondents in 2019 identified traveling alone to seek care as a
196 significant barrier to accessing care. Distance to healthcare facilities was also a substantial barrier to
197 accessing care in these regions of Senegal (identified as a barrier by 50% of female respondents in

198 Tambacounda, the largest region by geographical area). Sociodemographic characteristics of this survey
199 group are reported in Table S5 in the supplemental materials [30].

200 **Coverage over time by administrative region and geographic location**

201 DTP3 coverage from 2005 to 2019 by region in Senegal is reported in Figure 4 [31]. We observed that the
202 DTP3 coverage was consistently higher for the west and southwestern regions located near Dakar and
203 along the coast, and the variance of DTP3 coverage over time was consistently lower for this group of
204 coastal regions (t-test, $p=0.076$) compared to the group of eastern and northern regions. The region with
205 the lowest DTP3 coverage in 2019 was Kolda (73%), following a sharp drop in DTP3 coverage after 2017
206 compared to previous years. The rural and landlocked regions in the north and east demonstrated more
207 variability in coverage over time. However, among these regions, Tambacounda and Kedougou saw large
208 improvements, from 73% to 86% and 60% to 83%, respectively between 2017 and 2019; notably, Matam
209 saw the largest increase (from 73% to 100%) in coverage among all regions between 2010 and 2019.

210

211 *Figure 4 DTP3 coverage in Senegal by year and region (DHS 2005-2019). The regions of Kaffrine, Sedhiou, and Kedougou were*
 212 *split from existing regions in 2008 [31].*

213

214

215

216 **Discussion**

217 We conducted a study to assess the demographic associations of early childhood vaccination within
218 Senegal. Observing heterogeneities in DTP3 coverage across Senegal and comparing those differences
219 with demographic and geographic factors may aid decision-makers in addressing disparities in
220 vaccination access and uptake. Our analysis of household level data revealed associations between DTP3
221 coverage and 1) female literacy, 2) access to skilled prenatal care, and 3) challenges accessing care while
222 traveling alone.

223 Early childhood vaccination in Senegal steadily increased for all recommended vaccines from 2002 to
224 2007, with coverage remaining mostly constant through 2019 [11, 32-37]. Based on an analysis of
225 qualitative data including interviews with Senegalese administrators at various levels and focus group
226 discussions with caregivers and community health workers, Senegal’s immunization program has been
227 successful due to “*strong governance, collaboration, evidence-based decision-making, community*
228 *ownership, and an overall commitment to health and prioritization of vaccine programming from all*
229 *stakeholders and government officials.*”[11] Understanding the existing disparities between regions in
230 Senegal, alongside related factors, may support improvements in health equity through utilization of
231 Senegal’s existing governance structures and strong community health worker program.

232

233 *Female Literacy & Maternal Education.* We found that higher female literacy was significantly
234 associated with higher DTP3 coverage. Female literacy and higher maternal education have been shown
235 to be positively associated with higher vaccination coverage globally [18, 38-40]; it is atypical that
236 Senegal, with low female literacy at the national level [41], has relatively high DTP3 coverage compared
237 to other LMICs. While mothers with high literacy and education may be more likely to independently
238 seek vaccinations for their children [42], the health system in Senegal has been able to reach the more
239 vulnerable rural communities with lower female literacy through community health workers and
240 community-based health huts; “health huts are the backbone of Senegal’s community health system, and

241 they deserve much credit for Senegal’s impressive progress on disease prevention and treatment,
242 including its far-reaching immunization program” [9]. Involvement of community health workers such as
243 respected female elders known as “bajenu gox” have served as a link between the health care services
244 (i.e., health centers, health posts, health huts) and the communities, facilitating and coordinating
245 immunization outreach activities [10].

246
247 *Access to Healthcare Workers & Facilities.* We found that skilled prenatal care was associated with
248 higher DTP3 coverage in Senegal, which aligns with existing literature. Access to skilled healthcare
249 workers has an important role in childhood vaccination. Limited access to skilled prenatal care has been
250 linked to under-vaccination, or children not receiving all recommended vaccines [15, 43], and a prior
251 study highlighted an association between the number of skilled healthcare workers (nurses and midwives)
252 and DTP3 coverage using a cross-country analysis of developing countries around the world for the years
253 1990 to 2004 [40]. Self-reported barriers limiting access to care for women when seeking treatment,
254 namely traveling alone to healthcare facilities and travel distance, were associated with DTP3
255 vaccination. In regions with higher population density, women report fewer concerns regarding traveling
256 alone to access care when sick. Rural communities report more challenges than urban communities with
257 respect to accessing immunization services. Unfortunately, retaining skilled health workers is more
258 difficult in rural regions of Senegal [44]. Senegal has addressed these challenges through training
259 community health workers and health post staff, improving infrastructure for outreach services, increasing
260 capacity for health post expansion, and improving surveillance and data management at local levels [11].
261 In 2011, a 5-year \$40 million grant from USAID helped Senegal construct, maintain, and link more health
262 huts to the national health system [45].

263
264 Our results illustrate the role of contextual factors in relation to childhood vaccination. Although national
265 childhood vaccination coverage in Senegal is relatively high compared to other LMICs, there are still
266 gaps in coverage and disparities between regions which, similar to other studies, illustrate inequities in

267 deployment of vaccination services [12, 13]. National health programs rely on the consideration of
268 contextual factors and heterogeneity between subnational areas, such as those identified in this study, to
269 inform programmatic decision-making and improve health equity. Strategies for improving immunization
270 rates need to be tailored considering subnational differences; as stated in The Immunization Agenda 2030,
271 “reaching all people will require higher national vaccination coverage, but also less subnational inequity”
272 [46]. Subnational childhood vaccination has been negatively correlated with institutional mistrust [47].
273 Strong governance structures are required to prevent and address institutional mistrust while prioritizing
274 equity of healthcare access at the national level [11, 12, 48]. Subnational DTP3 coverage estimates have
275 been compared with national health spending, GDP per capita, and other governance indicators in sub-
276 Saharan Africa to investigate the drivers of equitable immunization services [49]. To reduce differences
277 in vaccination coverage between regions, and address institutional mistrust, national health policies and
278 programs should consider heterogeneity between and within regions. Senegal has implemented top-down
279 and bottom-up mechanisms for decision-making, planning, and resource allocation to address subnational
280 heterogeneity and allow for strategies and initiatives tailored for local populations [11].

281 Strengths and limitations

282 This work uses regionally representative data sets to explain associations between DTP3 coverage and
283 demographic and health system characteristics at the subnational level within Senegal, and evaluates
284 changes in vaccination coverage over time for each of these regions, considering the geographic location
285 of each region. We focused on analyzing respondent groups at the regional level or higher because DHS
286 surveys were not sampled to be representative at the smaller district level. Heterogeneities at the
287 subregional level were thus not evaluated. If district level data were available, we conjecture that negative
288 associations between DTP3 coverage and other factors, such as poverty, could be identified, given
289 heterogeneities at the subregional level. For instances where DTP3 immunization was determined based
290 on maternal recall, errors in recall could have biased results. Additionally, immunization is only reported

291 in the women’s questionnaire of the DHS survey; bias may exist due to families of children with no
292 mothers.

293 **Conclusions**

294 Senegal has improved vaccination coverage across its 14 administrative regions despite high poverty and
295 low female literacy as compared to other LICs and LMICs [19]. While coverage varies between regions,
296 high coverage has expanded in recent years beyond coastal and urban regions into the inland and rural
297 areas. National and regional efforts - especially increasing the number of health posts and huts to reach
298 rural communities and expanding the community health worker programs - have likely played an
299 important role [9]. Historically, the inland and rural regions have had variability in coverage over time;
300 future years will tell if the recent increases in coverage will be sustained.
