9

10 **Abstract**

11

12 Background: Acquired retinal diseases such as proliferative diabetic retinopathy and age-related macular
13 degeneration pose significant challenges in diagnosis and prognosis. The vitreous fluid, situated in the
14 posterior chamber of the eye behind the lens, holds a close relationship with the inner retina. Within this
15 milieu, retinal cells secrete a diverse array of biomolecules, potentially harboring vital biomarkers. Among
16 these, short, non-coding micro-RNAs (miRNAs) emerge as promising candidates. Their dynamic regulation
17 by various gene signaling mechanisms, enhanced resistance to degradation, and secretion via separate
18 exocytotic pathways make them particularly significant. Alterations in vitreal miRNA profiles may reflect
19 pathological states and offer insights into disease etiology and progression.

20 Abstract: We conducted a comprehensive meta-analysis of 22 peer-reviewed studies to assess the
21 potential of vitreous miRNAs as biomarkers for retinal diseases. Our analysis demonstrates the potential
22 utility of miRNAs as biomarkers in specific retinal pathologies. We show that miR-142, miR-9, and miR-21
23 emerge as robust biomarker candidates, displaying consistent and significant alterations correlating with
24 proliferative vitreoretinal diseases. We also address the methodological challenges encountered in

25 characterizing vitreous miRNA content, including the absence of standardized purification, amplification,
26 and analysis protocols, as well as the scarcity of true control samples. Moreover, we make the case for
27 the adoption of specific housekeeping genes and data normalization techniques to standardize miRNA
28 analysis in the vitreous and explore potential methodologies for obtaining vitreous samples from healthy
29 individuals.

30 Conclusion: Vitreous miRNAs hold promise as potential biomarkers for various retinal diseases, with miR-
31 142, miR-9, and miR-21 emerging as particularly promising candidates. Enhancing methodologies for
32 vitreous sampling and miRNA analysis presents an opportunity to expand the repertoire and utility of
33 miRNA biomarkers in retinal disease diagnosis and prognosis.

39 **Graphic abstract.** From left to right, the diagram shows the location of the retina and the vitreous humor
40 within the eye; the microanatomy of the retinal layers showcasing the secretion of exosomes and
41 biomolecules into the vitreous from its anterior side (inner retinal layers); a magnified illustration of
42 miRNA secretion process from gene expression in the cell nucleus to exosome -dependent and -

43 independent secretion pathways; and the process of intravitreal biopsy for collection and analysis of
44 miRNA expression using quantitative PCR methods.

45

46

47 **Background**

48 Retinal diseases can be hereditary, such as a retinitis pigmentosa, a disease affecting the
49 photoreceptor layer of the retina, while others are acquired. Acquired diseases may be related to
50 underlying cardiovascular disease (i.e. hypertensive retinopathy, retinal vein occlusion), diabetes mellitus
51 (i.e. non-proliferative diabetic retinopathy -NPDR-, proliferative diabetic retinopathy -PDR-), or
52 malignancy (i.e. melanoma, lymphoma). Other acquired retinal conditions are not directly caused by
53 systemic disease but are more likely to occur in patients with retinal risk factors. For example, patients
54 with pathological myopia (PM) and lattice degeneration are at greater risk for retinal detachment (RD)
55 (1). Lack of known genetic causes behind acquired retinal diseases precludes strategies aimed to
56 preventing their occurrence (e.g.: by preimplantation genetic screening), or to diagnose them before
57 onset, as it can happen with late onset inherited retinal dystrophies.

58 Moreover, as compared to hereditary retinal diseases, acquired retinal diseases are far more
59 prevalent in the population, and represent some of the most common causes behind vision loss and
60 blindness. For example, age-related macular degeneration (AMD) has a prevalence of over 10% in US
61 adults over the age of 40 and is the leading cause of blindness in elderly persons (2). Diabetic retinopathy
62 (DR) affects over 40% of the growing population of patients with diabetes mellitus (3). Many of these
63 diseases also progress over time. For example, both AMD and DR can progress to more severe forms,
64 characterized by abnormal growth of blood vessels in the retina (4, 5), which further deteriorates vision
65 in an irreversible way in the absence of treatment. As such, early detection of acquired retinal diseases is
66 critical to preventing further vision loss.

67 However, early diagnosis of retinal diseases can be challenging. Exam skills, such as
68 ophthalmoscopy, and imaging tools, like optical coherence tomography, enable visualization of the
69 affected layers of the retina in most diagnoses. However, not all diagnoses are clear, and sometimes
70 further investigation is required. For example, intraocular tumors can be mistaken for uveitis,
71 necessitating a chorio-retinal biopsy to rule out malignancy (6). Not only do biopsies provide a more
72 definitive diagnostic tool, but they can also further our basic scientific understanding of the molecular
73 pathology in the sampled tissue. Unfortunately, chorio-retinal biopsies are invasive procedures, and the
74 indications are limited to identifying infectious organisms affecting the retina, evaluating uveitis, and
75 excluding malignancy. As a result, for most retinal diseases which do not necessitate a diagnostic biopsy,
76 our understanding of the molecular pathogenesis is limited. Animal models, such as rodents, rabbits, dogs,
77 and non-human primates, have undergone retinal biopsies for the study of retinal disease (7-9). However,
78 the utility of animal models is limited by sample size for larger animals and differences in physiology and
79 anatomy between smaller animals and humans. Moreover, recapitulating a non-inherited disease in an
80 animal which does not develop the disease spontaneously, is complicated, time-consuming, and usually
81 produces partial results, where the gap between humans and model animals remains large.

82 Liquid biopsy of the vitreous humor may provide a less invasive alternative to the chorio-retinal
83 biopsy. The vitreous humor is a gel-like fluid filling the posterior chamber of the eye between the lens and
84 the retina, in direct contact with the inner retina. The vitreous is composed of water, hyaluronan,
85 hyalocytes (i.e. macrophages populating the posterior vitreous cortex), collagen and additional soluble
86 proteins (10). The vitreous is important for maintaining the round structure of the eye and plays a role in
87 refraction as light must pass through the vitreous to reach the retina (11). The vitreous humor is accessible
88 for liquid biopsy (i.e.: vitrectomy) via an incision in the sclera. Analogous to how cerebrospinal fluid is
89 collected through a lumbar puncture in order to evaluate central nervous system pathology, without the
90 need to access the brain or spinal cord, vitreous humor can be biopsied to study basic and clinical aspects

91 of retinal pathology (12). For example, in patients with PDR, retinal ischemia induces the release of
92 vascular endothelial growth factor (VEGF) in the retina, which then leaks into the vitreous body, resulting
93 in higher levels of vitreal VEGF (10, 13). In vitreoretinal diseases, such as PDR, proliferative
94 vitreoretinopathy (PVR), and rhegmatogenous retinal detachment (RRD), the inflammatory proteins AAT,
95 APOA4, ALB, and TF were found to be elevated compared to healthy controls, indicating that these
96 proteins may contribute to their pathogenesis (14). Similarly, patients with diabetic macular edema, AMD,
97 idiopathic epiretinal membranes (ERM), and macular telangiectasia type 2 show abnormal expression of
98 various proteins in the vitreous humor (15). Furthermore, the stability created by interaction between
99 hyaluronic acid and collagen fibrils within the vitreous also slows clearance, allowing persistence of
100 molecules associated with disease (10). The variations in vitreous composition reflecting retinal pathology
101 along with their persistence in the vitreous body suggest that the fluid may hold utility as a biomarker and
102 diagnostic tool. In the future, vitreous humor may surpass chorio-retinal biopsy and provide insight into
103 the pathogenesis of various retinal diseases.

104 One type of biomolecule found in vitreous humor is microRNA (miRNA), a class of small non-
105 coding RNA that regulates gene expression. For example, miRNAs may silence gene transcription under
106 certain conditions by hybridizing target messenger RNA (mRNA) to prevent protein translation or tag the
107 mRNA for degradation (16). Extracellularly, miRNAs mediate communication between cells, with effects
108 ranging from development of mesenchymal stem cells (17), to apoptosis of vascular cells (18). A benefit
109 of miRNAs as an extracellular entity, in contrast to other forms of RNA or proteins, is its size. Averaging
110 21-25 nucleotides, miRNAs are small enough to avoid nucleases and resist changes in heat and pH across
111 different bodily fluids (19). This characteristic has allowed miRNAs to serve as a potential biomarker for
112 many hematologic and solid cancers (20), temporal lobe epilepsy (21), acute myocardial infarction (22),
113 and sepsis (23).

114 Of the extracellular miRNAs found in vitreous humor, approximately 10% are secreted through
115 exosomes (24). Exosomes are extracellular vesicles, typically 40-160 nm, derived from endosomes and
116 secreted by most cell types, including those of the retina (25). Exosome vesicles contain cell constituents
117 such as proteins, lipids, RNA, and DNA, and can release their contents into neighboring or distant target
118 cells (26). Although the exact function of exosomes is unknown, this targeted transfer of contents suggests
119 that they are involved in intercellular communication. The potential roles of exosomes span widely across
120 wound healing, immunity, cellular differentiation, and more (25). Exosomes have been isolated in most
121 bodily fluids, including blood, saliva, urine, and cerebrospinal fluid, and the contents of these exosomes
122 have been found to be altered by disease (27). For example, serum levels of miR-21 have been significantly
123 increased in patients with esophageal and hepatocellular carcinoma (28, 29). Similarly, salivary exosome
124 levels of miR-1246 and miR-4644 are significantly higher in pancreato-biliary tract cancers, and the
125 combined levels of these miRNAs have potential as a sensitive screening tool for these cancers (30).
126 Furthermore, exosomal miR-142-5p and miR-223 were found to be significantly upregulated in breast milk
127 as an early detector of intramammary infection (31). However, while serum, saliva and breast milk are
128 accessible through safe and relatively simple collection methods, other fluids like cerebrospinal fluid and
129 vitreous require more invasive techniques and more advanced clinical skills, therefore limiting their
130 accessibility for research, and almost completely precluding the possibility of collecting control samples
131 from healthy counterparts.

132 In this meta-analysis, we searched the current literature for peer-reviewed scientific evidence
133 linking changes in vitreous composition with retinal disease, focusing on miRNA characterization and
134 quantification. Out of 126 studies that were screened, we found 22 that specifically addressed the
135 question of miRNAs in vitreous biopsies of retinal disease patients, and reanalyzed the data they provide.
136 Overall, our meta-analysis shows that vitreal miRNAs do serve as useful biomarkers in certain retinal
137 diseases such as proliferative diabetic retinopathy, age-related macular degeneration, and proliferative

138 vitreoretinal disease. However, the consistency of data regarding miRNA content in human vitreous is
139 limited by the fact that no gold standard for miRNA purification and amplification has yet been
140 established. Additionally, studies lack a source of true control samples as vitreous can only be collected
141 when a patient is undergoing vitrectomy, and patients only undergo vitrectomy when their eye is in some
142 state of disease. In recognition of these challenges, we propose using certain housekeeping genes and
143 data normalization techniques to standardize the analysis of miRNA in the vitreous, and we explore
144 potential methodologies for obtaining vitreous samples from healthy patients. Finally, we identify miR-
145 142, miR-9, and miR-21 as the strongest candidates for use as biomarkers of certain reginal diseases.
146 Specifically, these miRNAs were upregulated in proliferative diabetic retinopathy and proliferative
147 vitreoretinal disease.

148

149 **Main Text**

150 **1. Meta-analysis methodology**

151

152 ***Search methods for identifying studies.***

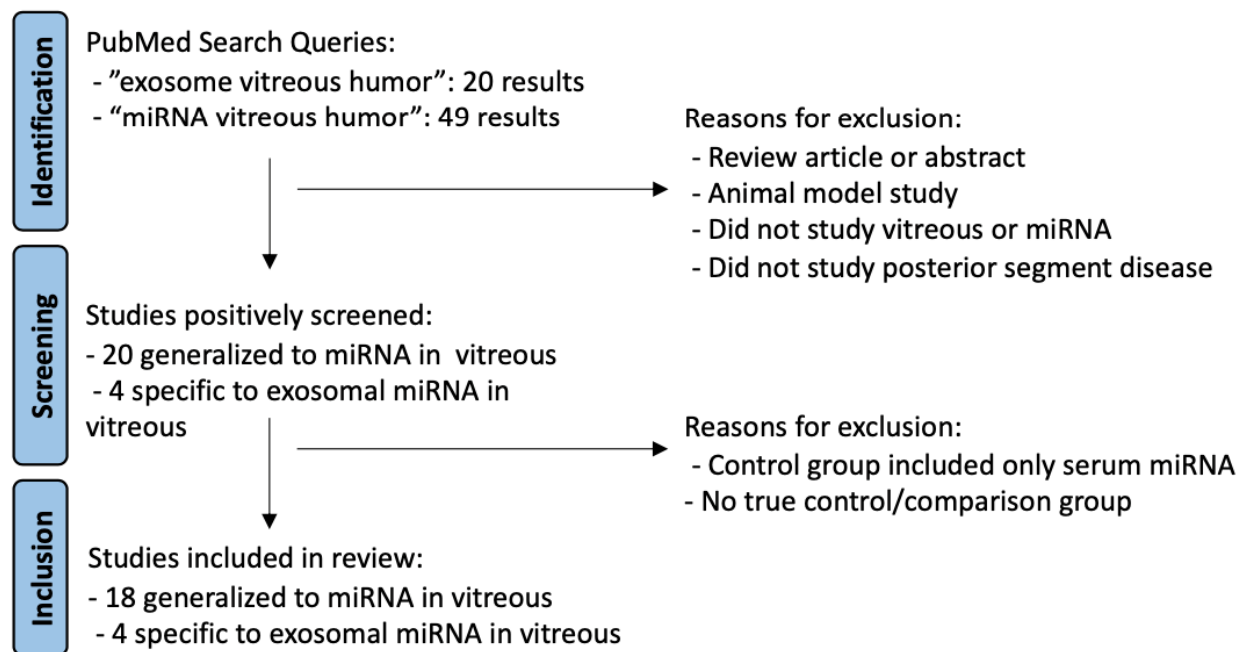

153 Studies were identified via PubMed search with the search terms “exosome vitreous” and
154 “microRNA vitreous” (**Figure 1**). The scope of articles was limited to studies published after 2012,
155 considering that there were no studies describing miRNA in vitreous humor prior to 2013 (12). The last
156 search was performed on January 23, 2024. All studies were reviewed by one reviewer, and selected
157 studies were confirmed by a second reviewer with subsequent resolution of conflicting ideas.

158

159 ***Eligibility criteria.***

160 All selected studies were peer-reviewed, primary research articles reporting original data. Only
161 studies that collected vitreous samples from human subjects were included. Selected studies researched

162 diseases that directly affect the retina, including primary retinal pathologies and metastases to the retina,
163 but excluded anterior segment diseases. With regards to methodology, all selected studies performed
164 miRNA isolation using a microarray kit from a tested manufacturer, such as Qiagen, Exiquon, or TRIzol,
165 followed by miRNA quantification with either qPCR, next generation sequencing (NGS), or a microarray
166 scanner. All studies must have tested significance of differential expression of miRNA, either exosomal or
167 non-exosomal, against control samples that were also derived from vitreous humor. Studies that had a
168 sample size less than 2 for any cohort were excluded. Studies that did not show evidence of miRNAs in
169 the vitreous were excluded as well.
170

171

172 **Figure 1. Flowchart describing search methodology and exclusion criteria.**

173

174 ***Data synthesis and analysis.***

175 Exosomal and non-exosomal miRNAs that were found to be dysregulated in disease were identified
176 within the selected studies as well as in any supplementary tables. Gene Ontology (GO) and Kyoto

177 Encyclopedia of Genes and Genomes (KEGG) analysis were conducted on these miRNAs using the DIANA
178 mirPath v.4 pathway analysis web server, analyzing the most commonly dysregulated miRNAs for disease
179 categories that had at least five relevant studies (32). When searching for commonly dysregulated
180 miRNAs, we first studied individual isoforms and then grouped them by mature miRNA family. Statistical
181 analysis was conducted through the DIANA mirPath v.4 software, using the “classical analysis” option,
182 which uses one-sided Fisher’s Exact tests to determine significance ($p < 0.05$).

183

184 **2. Meta-analysis results**

185 ***Vitreous humor sampling and molecular isolation.***

186 The studies assessing the potential of vitreous biopsies as a diagnostic tool included various
187 diseases but were limited to populations requiring vitrectomies. The studies also varied significantly in
188 their miRNA extraction and purification techniques due to the lack of a gold standard among the many
189 commercially available technologies designed to isolate and purify specific types of RNA.

190 The vitreous humor is routinely extracted in humans through an invasive procedure known as a
191 vitrectomy. Vitrectomies are routinely performed as treatment for RD, macular holes (MH), ERM,
192 posterior vitreous detachment, and vitreous hemorrhage. Vitrectomies may also be necessitated due to
193 complications in cataract surgery, such as posterior capsule rupture, which occurs in 0.45-7.9% of cataract
194 surgeries (33), and in patients with dislocated intraocular lens (34). While vitrectomies must be performed
195 in the operating room, vitreous humor can also be safely sampled in the clinic prior to intravitreal
196 injections, which are commonly done for the treatment of diabetic retinopathy, neovascular AMD, and
197 retinal vein occlusions (35). However, in-office sampling is not routine, and the studies reviewed were
198 thus limited to subjects who required vitrectomies as treatment. As such, control subjects did not have
199 non-pathological eyes but rather required a vitrectomy for visual disturbance from conditions such as
200 idiopathic floaters, MH, ERM. Therefore, control samples were defined as obtained from patients with

201 minimal risk of visual loss progression and blindness, as compared to the studied diseases. The
202 invasiveness of the vitrectomy limited the sample sizes of all studies.

203

204 After collecting the vitreous humor, all the studies, except those done by Liu et al. and Tuo et al., specified
205 that the vitrectomy samples were immediately stored at -80 °C prior to experimentation, to prevent RNA
206 degradation. After the frozen vitreous samples were thawed, miRNAs were isolated using commercially
207 available purification kits. The volume of vitreous humor collected through vitrectomy, varies from study
208 to study, and within patients in the same study, but was typically 1-5 ml. Although there are no RNA
209 isolation kits specifically designed for vitreous humor, studies have compared the efficacy of various kits
210 for use in small samples of other body fluids such as plasma and urine. For example, TRIzol reagent
211 (Invitrogen) has lower yield for miRNA with low guanine and cytosine content (36). However, the results
212 of TRIzol extraction aligns most closely with miRNA documented in the miRBase database compared to
213 miRNeasy mini kit (Qiagen) (37). Cell count and density of the sample also impact which isolation kit is
214 preferred. For miRNA extracted from cells in culture, both miRNeasy and TRIzol had greater RNA yields
215 than miRCURY (Qiagen) at lower cell counts, and miRNeasy outperformed both TRIzol and miRCURY at
216 both low and high cell densities (38). While a gold standard for miRNA isolation in vitreous humor has yet
217 to be established, the variability across isolation methods in other biofluids suggests a similar potential
218 for variability in vitreous humor, which may account for some of the differences across the reviewed
219 studies. Of the reviewed studies that isolated total miRNA, 13 used miRNeasy, 4 used TRIzol and 1 used
220 miRCURY.

221 To extract exosomal miRNAs, an additional step is required to isolate the exosomes first.
222 Exosomes can either be isolated from vitreous humor via a combination of ultracentrifugation and
223 filtration, known as differential centrifugation, or via centrifugation followed by an exosome isolation kit
224 such as miRCURY Exosome Kit (Qiagen) or RiboTM Exosome Isolation Reagent (RiboBio). Differential

225 centrifugation is considered the gold standard for exosome isolation, and isolation kits may lead to the
226 inclusion of non-exosomal particles (39). However, ultracentrifugation requires costly equipment that
227 isolation kits avoid. Of the reviewed studies which isolated miRNA from exosomes, two used differential
228 centrifugation, while two employed an isolation kit.

229

230 *miRNA changes in total vitreous biopsy across diseases.*

231 The reviewed studies varied in their level of specificity when reporting dysregulated miRNA
232 expression. For example, some reported the mature miRNA family that was dysregulated (e.g.: miR-125)
233 while others also included a suffix (i.e.: -3p, -5p), specifying an isoform within the miRNA family. miRNA
234 isoforms were considered separate molecules and are denoted by different letters (e.g.: miR-125a vs miR-
235 125b). When searching for the most commonly dysregulated miRNAs across all of the studies, we included
236 both the overall miRNA families, as well as individual isoforms.

237 With regards to the miRNA families, miR-16 was most commonly dysregulated, with 9 occurrences
238 in 7 different studies (**Table 1**). miR-16 was upregulated in all instances except in the case of PM, where it
239 was downregulated. This may reflect the pathogenesis of PM compared to the other diseases. While PM
240 is characterized by chorio-retinal atrophy, all the other pathologies involved proliferative or cancerous
241 processes. In addition, the study on PM included controls that had RRD. The inflammatory and immune
242 reaction to RRD could cause miRNA dysregulation, making miR-16 relatively downregulated in subjects
243 with PM. Other commonly dysregulated miRNA families include miR-125b, miR-139, and miR-423, as
244 described in **Table 1**.

245 Comparing specific isoforms, miR-423-5p was most frequently dysregulated with 6 different
246 studies finding it to be upregulated, as seen in **Table 1**. The next most frequently dysregulated miRNA was
247 miR-320b, which does not have -3p or -5p isoforms according to the miRBase database. miR-320b was

248 consistently upregulated in 5 different studies investigating PDR, PM, and primary vitreoretinal lymphoma
 249 (PVRL) (40-44).

 252 the most commonly dysregulated miRNA across all diseases included in the present meta-analysis. PVRD:
 253 proliferative vitreoretinal disease, UM: uveal melanoma, DM: diabetes mellitus, PDR: proliferative

254 diabetic retinopathy, PVRL: primary vitreoretinal lymphoma, PM: pathologic myopia, NPDR: non-
255 proliferative diabetic retinopathy, PVR: proliferative vitreoretinopathy

256

257 ***miRNA in diabetic retinopathy***

258 DR can be categorized as NPDR, the less severe form, or PDR, the more advanced form, which is
259 characterized by breakdown of the barrier between the retina and its surrounding blood vessels (3). Of
260 the ten articles in our analysis that studied DR, only one studied NPDR while the remaining nine focused
261 on PDR. Pramanik et al. compared miRNA in Type 2 DM patients with and without NPDR and found that
262 NPDR patients had significantly decreased levels of miR-126 and miR-132 in both the vitreous humor and
263 plasma (45). Furthermore, ROC curve analysis showed that the fold change of miR-126 and miR-132 in the
264 vitreous humor had greater sensitivity and specificity as a predictor of NPDR compared to the fold change
265 in plasma, indicating that the vitreous miRNAs have better diagnostic utility for retinal disease than serum
266 miRNA (45). Of the seven studies in our analysis that researched PDR, the two studies by Liu et al. and Kot
267 et al. specifically isolated exosomal miRNA and are detailed further in section 3.3.1 below, while the
268 remaining seven articles studied miRNA found in the total vitreous humor.

269 Given that abnormal blood vessel growth is part of the pathogenesis of PDR, several of the studies
270 correlated miRNA that were dysregulated in PDR with angiogenesis. For example, Hirota et al. identified
271 five miRNAs (miR-15a, miR-320a, miR-320b, miR-93, and miR-29a) that were significantly elevated in the
272 vitreous humor in patients with PDR and thought to be involved in angiogenesis (40). For example, miR-
273 15a has been shown to inhibit angiogenesis in response to ischemia by reducing the activity of fibroblast
274 growth factor 2 and VEGF, indicating that miR-15a may have protective effects in PDR (46). Guo et al.
275 identified three miRNAs (miR-24-3p, miR-197-3p, and miR-3184-3p) that were not only significantly
276 upregulated in PDR but also correlated with increased levels of VEGF and transforming growth factor- β
277 (TGF β) in the vitreous humor (43). In contrast, Gomaa et al. showed that miR-200b was elevated in PDR

278 but it did not correlate with vitreous levels of VEGF (47). Yang et al. identified seven miRNA that were
279 elevated in PDR, and KEGG analysis showed that the target genes of these miRNA were most enriched in
280 the Th17 cell differentiation pathway (48). Notably, interleukin-17, which is produced by Th17 cells, has
281 been shown to promote retinal neovascularization through multiple mechanisms (49-51).

282 The high glucose conditions caused by diabetes also contribute to the pathogenesis of PDR,
283 Shanbagh et al. specifically studied how these conditions affected miRNA and target protein levels (52).
284 They found that miR-182-5p was upregulated in patients with PDR, and under high glucose conditions,
285 RPE cells had higher expression of miR-182-5p. The study also showed that the downstream effects of
286 elevated miR-182-5p expression included downregulation of FoxO1 and upregulation of Akt and HK2,
287 which are known to be involved in metabolic regulation (53, 54). These findings show that miR-182-5p
288 may have a role in the pathogenesis of PDR through its effects on glucose metabolism.

289 Smit-McBride et al. differentiated between Type 1 and Type 2 DM when studying miRNA in the
290 vitreous of patients with PDR. They identified four miRNA families (let-7, miR-320b, miR-4488, and miR-
291 762) that were upregulated in patients with PDR with both types of DM as compared to controls with MH
292 or macular pucker (41). Although these miRNAs have not been studied in the retina, let-7 targets
293 regulatory cytokines that promote angiogenesis and has been linked to increased risk of Type 2 DM (55,
294 56). Interestingly, miR-320b has been shown to be anti-angiogenic via its regulation of neuropilin 1 and
295 insulin-like growth factor 1, indicating that the increased levels of miR-320b in PDR may be a
296 compensatory mechanism attempting to attenuate disease progression (57, 58).

297 Because the retinal blood vessels that form in PDR are abnormal, they are at high risk of bleeding
298 into the neighboring vitreous humor. Mammadzada et al. were the only researchers to specifically look at
299 PDR that was complicated by recurrent vitreous hemorrhage. They found that miR-20a and miR-93 were
300 significantly elevated in patients who later developed recurrent vitreous hemorrhage, and both miRNA
301 are known to be involved in angiogenesis. Increased levels of miR-20a have been shown to downregulate

302 VEGF protein expression, but miR-20a is also known to be downregulated by hypoxic conditions (59). Of
 303 note, miR-20a was also found to be elevated in the study by Friedrich et al. (60). miR-93, which was also
 304 found to be upregulated in the study by Hirota et al., has been shown to modulate angiogenesis through
 305 multiple mechanisms, including by directly binding the VEGF-A gene and by promoting endothelial cell
 306 proliferation and migration by targeting cyclin-dependent kinase inhibitor 1A (59, 61, 62)

307 Given that VEGF is considered a primary driver of neovascularization in PDR, anti-VEGF
 308 medications have become a standard treatment and have been shown to improve visual acuity in PDR
 309 (63). Friedrich et al. not only identified miRNA that were elevated in PDR but also found that miR-23b-3p
 310 levels were subsequently lowered after anti-VEGF treatment (60). Further investigation into the targets
 311 of miR-23b-3p is needed. Overall, there were three families of mature miRNAs that were found to have
 312 four isoforms dysregulated in at least three of the nine studies, as shown in **Table 2**.

313

miRNA	Study	Isoform	Up- or Down- Regulation	Enriched Signaling Pathways
miR-142	Kot 2022	miR-142-3p	↑	p53***

314 **Table 2. Correlation between changes in human vitreous miRNA expression and PDR.** The table shows
 315 the miRNA families with 24 instances of dysregulation, across studies, in PDR; and the molecular signaling
 316 pathways they affect related to diabetes, with or without retinopathy. *p<0.01, **p<0.001, ***p<0.0001.

317
 318 KEGG analysis through the DIANA-miRPath database showed that all three miRNA families (miR-
 319 142, miR-423, and miR-9) were connected to pathways in diabetes and diabetic retinopathy. For example,
 320 all three are involved in the p53 signaling pathway, which is known to be connected to Type 2 Diabetes
 321 Mellitus (DM), because p53 inhibition preserves pancreatic insulin secretion (64). Furthermore, p53
 322 protein and mRNA have been shown to be upregulated in retinal pericytes and human retinal vascular
 323 endothelial cells under high glucose conditions, showing a possible role in the early development of
 324 diabetic retinopathy (65, 66). One limitation of KEGG analysis is that although it can determine whether a
 325 miRNA targets a certain pathway, it does not specify whether the pathway is enhanced or suppressed by
 326 the miRNA. In this case, if the miRNA were shown to upregulate the p53 signaling pathway, that would
 327 provide further evidence in their role in the pathogenesis of PDR.

328 The VEGF signaling pathway is considered a primary driver for the vascular proliferation that
 329 characterizes PDR (67, 68). Only miR-142 directly enriched the VEGF signaling pathway, but both miR-142
 330 and miR-423 enriched related pathways. For example, miR-423 targeted the hypoxia-inducible factor
 331 (HIF)-1 signaling pathway, which is known to increase retinal VEGF in diabetic retinopathy. As its name
 332 suggests, HIF-1 is induced by small vessel hypoxia in the retina created by diabetes and then mediates
 333 retinal neovascularization through the release of VEGF and erythropoietin (69-72). Therefore, miRNA that
 334 activate HIF-1 signaling would theoretically worsen diabetic retinopathy while miRNA that suppress it

335 could be protective. Further research is required to determine how miR-423 levels correlate with HIF-1.
336 Similarly, miR-142 and miR-423 targeted the phosphatidylinositol 3-kinase (PI3K)-Akt signaling pathway.
337 Activation of PI3K-Akt can increase VEGF expression by upregulating the HIF-1 signaling pathway or by
338 phosphorylating endothelial nitric oxide synthase, which is a necessary step in VEGF-induced angiogenesis
339 (73, 74). miRNA activation of the PI3K-Akt pathway would increase neovascularization in PDR. Both miR-
340 423 and miR-9 enriched the MAPK signaling pathway, which is activated by the VEGF signaling pathway,
341 and is known to cause retinal inflammation and fibrosis in PDR (75). In fact, MAPK inhibition in retinal
342 mouse models decreased inflammatory and angiogenic markers such as nitric oxide and cyclooxygenase-
343 2 (76, 77). Upregulation of MAPK by miRNA would thus contribute to the development of PDR.

344 When evaluating the use of the miRNAs as biomarkers for PDR, both their specificity and
345 consistency must be considered. Although miR-423 is consistently found to be upregulated in PDR, it is
346 also commonly upregulated in other disorders such as PM and PVRL (**Table 1**). This lack of specificity for
347 PDR indicates that miR-423 may be a more general marker of retinal cell dysfunction. On the other hand,
348 although miR-9 was not found to be dysregulated as frequently as miR-423, its results were inconsistent.
349 Forms of the miR-9 family were downregulated in the study by Kot et al. but upregulated in the studies
350 by Liu et al. and Guo et al (43, 78, 79). These differences may be due to variations in subject choice and
351 study design. In the study by Kot et al., the PDR subjects had disease that was complicated by tractional
352 RD, meaning the PDR was severe enough to produce a fibrous proliferative membrane that created
353 enough traction to cause detachment of the neurosensory layer of the retina (80). In the other two
354 studies, the PDR was not complicated by tractional RD, and the RD and its treatment may have impacted
355 the miRNA composition. Also, Kot et al. used qPCR to quantify assayed miRNA while Liu et al. and Guo et
356 al. used NGS. Although Guo et al. verified the results of their NGS with qPCR, the initial choice of miRNA
357 quantification technique may have led to varied results. Until these discrepancies can be resolved, the
358 utility of miR-9 as a biomarker is limited. miR-142, however, was consistently upregulated across studies

359 and was more specifically upregulated in the setting of PDR. This, combined with its direct and indirect
360 influence on the VEGF pathway, makes miR-142 an important potential biomarker for PDR.

361 The three most commonly dysregulated miRNA families, with at least four instances of
362 dysregulation in at least three different studies, listed in **Table 2** as well as the 16 next most commonly
363 dysregulated miRNA families, with at least three instances of dysregulation (Supp. Table 1) were selected
364 for pooled GO and KEGG analysis (see **Figure 2 & 3**). KEGG analysis resulted in 141 related pathways.
365 Notably, ubiquitin-mediated proteolysis, protein processing in the endoplasmic reticulum, cell cycle, and
366 p53 signaling pathways, are all related to Type 2 DM according to the KEGG pathway database. GO analysis
367 revealed 1174 targeted categories, with 547 results in the biological component domain, 163 in molecular
368 function, and 245 in the cellular component.

369

370

371 **Figure 2. KEGG analysis of human vitreous miRNAs in PDR.** Top 10 most enriched KEGG pathways for the
372 19 most commonly dysregulated (23 instances of dysregulation) miRNA species in proliferative diabetic
373 retinopathy, including 41 isoforms. The miRNA number indicates the number of inputted miRNAs that are
374 involved in each pathway and the gene number indicates the number of experimentally validated target
375 coding-genes of the inputted miRNAs that are involved in each pathway. The top 10 pathways had p-
376 values <1E-11 (one-sided Fisher's exact test, p<0.05).
377

378
379 **Figure 3. GO-terms analysis of human vitreous miRNAs in PDR.** Top 10 most enriched GO terms for the
380 19 most commonly dysregulated (23 instances of dysregulation) miRNA species in proliferative diabetic
381 retinopathy, including 41 isoforms. The top 10 terms had p-values <1E-49 (one-sided Fisher's exact test,
382 p<0.05).
383

384 ***miRNA in proliferative vitreoretinal disease***

385 Proliferative vitreoretinal disease (PVRD) is a category encompassing diseases with a proliferative
386 element to their pathogenesis, including PVR following trauma or RD and PDR. In our analysis, the study
387 by Usui-Ouchi et al. encompassed both PDR and PVR, and Toro et al. focused on PVR due to RD (81, 82).
388 We identified 25 of the most commonly dysregulated miRNAs (with at least 3 instances of dysregulation)
389 among these two studies as well as the 9 looking at PDR alone (Supp. Table 2). As with PDR alone, the
390 miR-9 and mir-423 families were two of the most commonly dysregulated, with miR-9-5p upregulated in
391 PVR and miR-423-5p upregulated in general PVRD. GO and KEGG analysis of these 50 miRNAs showed
392 almost complete overlap with the results from PDR alone. However, one notable difference was that the
393 p53 signaling pathway was not in the top 10 most enriched pathways for PVRD although it was for PDR
394 alone. As noted above, the p53 signaling pathway is known to be related to the pathogenesis of Type 2
395 DM, so it is reasonable that this pathway would be less targeted in PVR, a non-diabetic process. Instead,
396 the neurotrophin-signaling pathway was in the top KEGG pathways for PVRD, although it was not among
397 the most enriched pathways in PDR.

398 Usui-Ouchi et al. argue that the shared proliferative process in PDR and PVR would lead to similar
399 alterations in miRNAs. In particular, they highlight miR-21 as increasing in relation to retinal fibrosis in
400 PVRD. In fact, miR-21-5p is found to be upregulated in the studies by Guo et al. and Kot et al looking at
401 PDR. However, miR-21-3p is downregulated in the PVR study by Toro et al. This discrepancy highlights the
402 need for specification of miRNA isoforms across studies. Although both isoforms have the same mature
403 miRNA, the differences in their precursors could affect how they correlate to pathology. In the past,
404 studies may have been limited by the available microarrays, but moving forward, researchers should aim
405 to specify the miRNA isoforms.

406 Another miRNA that may be involved in the pathogenesis of PVR is miR-148a-3p, which was found
407 to elevated in patients with retinal detachments (83). Although the study subjects did not yet have

408 progression to PVR, Takayama et al. showed that transfection of miR-148a-3p into human retinal pigment
 409 epithelium (RPE) cells promoted epithelial–mesenchymal transition, a process that characterizes PVR (83,
 410 84).

411

412 ***miRNA in primary vitreoretinal lymphoma.***

413 Two studies, by Tuo et al. and Minezaki et al., identified miRNA that are dysregulated in primary
 414 vitreoretinal lymphoma (PVRL) in comparison to uveitis (44, 85). Because PVRL can be mistaken for uveitis,
 415 leading to delay in proper treatment, there is need for a distinguishing biomarker. The miRNAs found to
 416 be dysregulated in PVRL compared to uveitis in both studies can be found in **Table 3**, but only the results
 417 from Minezaki et al. are statistically significant.

418

miRNA	Study	Tail	Up- or Downregulation
miR-200c	Tuo 2013	-	↓
	Minezaki 2020	miR-200c-5p	↑*
miR-484	Tuo 2013	-	↑
	Minezaki 2020	-	↑*
miR-197	Tuo 2013	-	↑
	Minezaki 2020	miR-197-3p	↑*
	Minezaki 2020	miR-195-5p	↑*
miR-132	Tuo 2013	-	↑
	Minezaki 2020	miR-132-3p	↑*

419 **Table 3. Dysregulated human vitreous miRNA in PVRL, as compared to uveitis.** Only the results reported
 420 by Minezaki et al. were statistically significant (t-test, *p<0.05).

421

422 Tuo et al. focused on miR-155, which they not only found to be significantly decreased in
423 lymphoma patients but was also inversely correlated with IL-10, which is known to be secreted heavily in
424 B-cell PVRL. However, miR-155 was not found to be dysregulated by Minezaki et al. One reason for the
425 variation in significance and miRNAs identified between the two studies may be their sample sizes. Tuo et
426 al. had only 3 PVRL and 3 uveitis samples for the microarray while Minezaki et al. had 6 each. However,
427 Tuo et al. confirmed the results of the microarray with individual assays and qPCR from a larger sample of
428 17 PVRL and 12 uveitis subjects. Minezaki et al. used a microarray scanner to quantify the miRNAs and did
429 not validate the results with qPCR. Also, the choice of microarray may have impacted the
430 comprehensiveness of study results. The microarray used by Tuo et al. (the microRNA-CURY panel from
431 Exiquon) tested for only 168 miRNAs while the 3D-Gene miRNA Oligo Chip used by Minezaki et al. tested
432 for 2565 miRNAs. Further studies comparing miRNA in PVRL and uveitis should employ large-scale
433 microarrays as done by Minezaki et al. but with the secondary validation schema outlined by Tuo et al.

434

435 ***miRNA in pathologic myopia.***

436 PM is defined by an axial length of at least 26.5 mm or a refractive error of at least -6.00 diopters.
437 Patients with PM are at risk for progressive vision loss due to chorioretinal atrophy as well as RD. Two
438 studies in our review analyzed changes to non-exosomal and exosomal miRNA in the vitreous humor of
439 subjects with PM. Ando et al. found that let-7c was upregulated in PM while miR-200a was downregulated
440 (86). These results are confirmed by You et al., who found let-7c-5p to be upregulated while miR-200a-3p
441 was downregulated in PM (42). Ando et al. argued that let-7c may be secreted by Müller glial cells
442 migrating to the inner limiting membrane of the retina in highly myopic eyes. KEGG pathway analysis of
443 miR-200a completed by Ando et al. showed that the let-7c was related to the PI3K/Akt signaling pathway,
444 which may increase axial length by stimulating proteins such as insulin-like growth factor-1 and matrix
445 metalloproteinase-2, which are known to be related to PM. You et al. identified 143-3p and miR-145-5p

446 as key miRNA through weighted gene co-expression network analysis. Like Ando et al., You et al. showed
447 that miR-143-3p and miR-145-5p may relate to axial length by potentially increasing the expression of
448 insulin-like growth factor. One reason that Ando et al. may not have detected dysregulation of miR-143-
449 3p and miR-145-5p is that these miRNAs were detected within exosomes. As discussed later in this review,
450 exosomal miRNA can be more stable than non-exosomal miRNA and thus serve as more reliable
451 biomarkers.

452

453 ***miRNAs in age-related macular degeneration.***

454 The pathogenesis of AMD involves several layers of the retina: the photoreceptor layer becomes
455 less dense, there is hyperpigmentation and atrophy of the RPE, and lipid-rich materials known as drusen
456 are deposited between the RPE and Bruch's membrane (4). In the more advanced form, wet or
457 neovascular AMD, there is neovascularization of the macula (4). Despite its prevalence, to the best of our
458 knowledge, there is only one study looking at miRNA in the vitreous humor in neovascular AMD. Menard
459 et al. noted upregulation of miR-146a and downregulation of miR-106b and miR-152 in patients with
460 neovascular AMD compared to controls (87). The study goes on to argue that the ratio of miR-146a to
461 miR-106b collected from both vitreous humor and plasma can be used as a biomarker for neovascular
462 AMD, based on receiver operating characteristic (ROC) analysis. According to Menard et al., miR-146a may
463 have a protective mechanism in the retina by downregulating inflammatory cytokines. Meanwhile,
464 decreased miR-106b levels may worsen neovascular AMD by influencing VEGF-A and IL-8 regulation. This
465 was the only study to consider the ratio of two miRNA as a biomarker, but while this approach is unique,
466 it comes with limitations. miR-146a and miR-106b are proposed to have separate mechanisms for
467 advancing neovascular AMD, so if one of these mechanisms progresses at a slower-than-expected rate,
468 then the ratio will be skewed. This study's sample size was 26, but a larger follow-up study could be used
469 to verify the findings and establish a diagnostic range for the ratio.

470

471 ***miRNAs in intraocular tuberculosis.***

472 Intraocular tuberculosis (IOTB) can occur as a result of systemic tuberculosis or via direct infection
473 of the eye. Although it most commonly presents as posterior uveitis, it can also affect the retina, usually
474 through spread from the choroid, presenting as focal tubercles, subretinal abscesses, or diffuse retinitis
475 (88). These findings are thought to be caused by an inflammatory response to bacteria-laden
476 macrophages depositing their contents in the ocular blood supply (89). To our knowledge, only one study
477 has analyzed vitreous-derived miRNA. Chadalawada et al. used NGS followed by validation with qPCR to
478 identify 3 miRNA (miR-150-5p, miR-26b-5p, and miR-21-5p) that were upregulated in IOTB compared to
479 controls with MH (90). Furthermore, the study used ROC analysis to identify a combination of miR-21-5p
480 and miR-26b-5p as having the highest potential as a biomarker. Interestingly, the study noted that miR-
481 21-5p may have immune regulated anti-inflammatory effects in IOTB, which contrasts with miR-21's pro-
482 fibrotic role in the pathogenesis in PVRD as discussed above. Given that miR-21 isoforms have been found
483 to be dysregulated in 5 of our studies, it is important that further research is done to investigate its
484 mechanism of action in retinal diseases.

485

486 ***Exosomes in disease.***

487 Exosomal miRNA may be even better markers of retinal disease than non-exosomal RNA.
488 Exosomes are secreted into the vitreous humor by surrounding cells, such as retinal cells, providing
489 miRNAs that reflect the state of the diseased parent cell (91). Exosomal miRNAs are protected from
490 degradation by RNAses and show increased stability. In addition, exosomes have specific proteins and
491 markers, and this uniqueness allows for more targeted analysis of low abundance exosomal cargo (91).
492 Within the vitreous humor, exosomes are particularly good choice for finding biomarkers due to their
493 abundance. Over 60% of proteins isolated from vitreous humor are consistent with exosomes, according

494 to gene ontology analysis of vitreous humor proteins (92). Moreover, almost 50% of the vitreous humor
 495 proteins thought to be within the exosomes are associated with retinal disease, furthering the argument
 496 that exosomal cargo can be used as indicators of retinal health (92). In fact, studies have already shown
 497 that vitreous humor exosomes may affect immunomodulation and angiogenesis (93, 94). Here, we review
 498 how exosomal miRNA vary with disease and evaluate their potential as biomarkers.

499

500 ***Exosomal miRNA.***

501 Thus far, there are only four studies that have identified dysregulated miRNA in exosomes from
 502 the vitreous humor. The most notable miRNAs from each study are outlined in **Table 4**. Both Ragusa et al.
 503 and You et al. used differential ultracentrifugation, the gold standard, to isolate exosomes from vitreous
 504 humor, while Kot et al. and Liu et al. used a combination of centrifugation and an exosome isolation kit.

505

Study	Disease	Control	Sample Size	miRNA	Up- or Down-regulation
Ragusa 2015	UM	Healthy cornea donors	6 UM	miR-21	↑
			6 control	miR-34a	↑
				miR-146a	↑
				miR-618	↑
Liu 2022	PDR	MH	10 PDR	miR-9-3p	↑
			15 control	miR-23b-3p	↑
				miR-1285-3p	↑
				miR-4685-3p	↑
Kot 2022	PDR with	MH	10 PDR with	miR-21-5p	↑
	TRD		TRD	miR-125a-5p	↓

			10 control	miR-125b-5p	↓
				miR-204-5p	↓
				miR-412-3p	↓
				let-7g-5p	↑
You 2023	PM-L and PM-H	RRD, MH, or ERM	5 PM-L	miR-26a-5p	↓ ⁺
			8 PM-H	miR-204-3p	↓ ⁺
			12 control	miR-204-5p	↓ ⁺
				miR126-3p	↓ ⁺
				miR-143-3p	↓
				miR-145-5p	↓
				miR-151a-3p	↓ ⁺

506 **Table 4. Dysregulated miRNA found within human vitreal exosomes.** Summary of miRNA within vitreous
507 humor exosomes that have thus far been studied and identified as dysregulated in comparison to the
508 listed controls ($p < 0.05$). UM: uveal melanoma, MH: macular hole, PDR: proliferative diabetic retinopathy,
509 TRD: tractional retinal detachment, PM-L: low grade pathologic myopia, PM-H: high grade pathologic
510 myopia, RRD: rhegmatogenous retinal detachment, ERM: epiretinal membrane. The table includes select
511 miRNA that were emphasized in the primary study, see original publication for full list of dysregulated
512 miRNAs. Up- or down- regulation noted with '+' is comparing miRNA in PM-H to miRNA in PM-L, rather
513 than to the control group.

514
515 Ragusa et al. was the first to look at exosomal miRNA in the vitreous humor, and they did so in
516 the context of uveal melanoma (UM). The study looked at non-exosomal miRNA as well and found that
517 there was a 90% overlap between non-exosomal and exosomal miRNA in UM, indicating that the non-

518 exosomal miRNA may have altered by exosomes. Considering how exosomal miRNA reflect the parent
519 cells, the study argues that miR-21 and miR-146a, which were found to be upregulated, come from
520 neighboring neoplastic melanocytes. They show this by demonstrating that miR-146a was also
521 upregulated in formalin-fixed paraffin-embedded UM specimens. A limitation of this study, however, is
522 the choice of subjects. The vitreous humor was taken from enucleated eyes for the UM group and cornea
523 donors for the control group. The miRNA composition, both exosomal and non-exosomal, could be altered
524 by the removal of the eyes.

525 While shared miRNA dysregulation between Liu et al. and Kot et al. was discussed in the section
526 on miRNA in PDR, the study by Liu et al. has further importance regarding exosomes. Liu et al.
527 demonstrated that retinal Müller glia cells secrete exosomes containing miR-9-3p, and these miRNAs
528 promote angiogenesis via overexpression of sphingosine 1-phosphate receptor 1 (S1P1). Again, this shows
529 a direct connection between retinal cells and miRNA within vitreous humor exosomes. However, although
530 this connection was demonstrated *in vivo*, it utilized a mouse model, which has limited transferability to
531 humans. Further study in humans and animal models will be required to determine the exact role of
532 exosomal miR-9-3p in PDR.

533

534 **Conclusions**

535 The objective of this meta-analysis was to assess the potential usefulness of miRNAs identified in
536 vitreous humor as biomarkers and diagnostic aids for a range of acquired retinal diseases. Among 126
537 initial studies surveyed, only 22 presented pertinent data concerning the composition of miRNAs in human
538 vitreous biopsies within the context of retinal disease, covering conditions such as PDR, PVRD, PVRL, PM,
539 AMD, and intraocular TB. Our revision of published data reveals promising prospects for utilizing miRNA
540 molecular analysis in human vitreous biopsies as a feasible means of identifying and quantifying clinically
541 relevant biomarkers. Moreover, the exploration of vitreous miRNAs holds potential for offering valuable

542 insights into the molecular mechanisms underlying various retinal diseases. Nonetheless, significant
543 challenges lie ahead, including the variability in extraction and purification methodologies, the
544 establishment of robust criteria for selecting control samples, the identification of suitable and universally
545 applicable housekeeping genes, and the validation of predictive capabilities for each proposed marker.
546 Addressing these challenges will be crucial for advancing the clinical translation of miRNA-based
547 diagnostics in retinal disease.

548 Our analysis revealed that variability across miRNA isolation and purification kits generally did not
549 affect the consistency of results. However, differences in amplification methods may have contributed to
550 contradictory findings. For instance, in three studies using three different kits (Kot et al. used miRCury,
551 Friedrich et al. used TRizol, and Guo et al. used miRNeasy), all three found miR-142 to be upregulated in
552 PDR (43, 60, 78). Nevertheless, while Kot et al. used qPCR for miRNA quantification, Liu et al. and Guo et
553 al. initially used NGS, potentially accounting for their disparate findings regarding miR-9 dysregulation in
554 PDR. Although no gold standard exists for miRNA quantification in vitreous biopsies, studies on limited
555 volumes of serum and plasma recommend initial quantification with NGS followed by validation with qPCR
556 to maximize miRNA detection sensitivity and reliability (95). While varying results among isolation kits and
557 amplification techniques have been investigated in other human biofluids, the emerging nature of this
558 field means there is yet no gold standard for miRNA extraction and quantification from vitreous humor,
559 affecting the quality of results.

560 Due to the invasiveness of a vitrectomy, all subjects in the studies, including those considered
561 ‘controls’, had a clinical indication for a vitrectomy, creating a lack of a *true control*. Most of the control
562 cases required vitrectomies for idiopathic MH, ERM, or floaters, all of which are conditions caused by age-
563 related changes to the vitreous. However, the pathophysiology of MH remains unknown, while the
564 pathophysiology of ERM includes cell proliferation and fibrosis, which may also be occurring in the studied
565 diseases, obscuring data (96, 97). For example, Russo et al. found that miR-19b, miR-24, and miR-142-3p

566 were significantly upregulated in patients with idiopathic MH or ERM compared to idiopathic floaters (98).
567 The miR-142 family was also found to be commonly upregulated in PDR when compared to controls with
568 MH, indicating that there may be overlap in the pathogenesis of these idiopathic conditions and PDR.

569 For vitreous-derived miRNAs to be proven as biomarkers and indicators of pathogenesis, studies
570 must use controls that do not have any underlying pathologies, but this is made challenging due to the
571 invasiveness of a vitrectomy. Currently, most miRNA purification kits work reliably in fluid samples of
572 ~100-200 μ l, while the human vitreous volume is estimated at ~4.0 ml (99). A current alternative to
573 vitrectomies would be to obtaining vitreous samples during intraocular injections. However, this restricts
574 the collection of samples exclusively to those receiving the treatment in question. Future vitreous biopsy
575 techniques with minimal invasiveness could involve the use of thinner and smaller catheters and needles,
576 to extract a very small volume (<100 μ l) from awake patients, eliminating the use of vitrectomy- or
577 injection-dependent biopsies.

578 Variations in miRNA expression across studies could also be caused by different strategies for
579 normalizing miRNA quantification data. Our studies reported 3 different normalization techniques – 7
580 used a housekeeping gene, 5 used an exogenous control, and 9 normalized against a weighted or
581 unweighted average or median expression of the miRNA quantities. The housekeeping gene used by all 7
582 studies was the small nuclear-RNA U6, a widely used reference gene. A review of miRNA-analysis using
583 qPCR in cancer studies showed that 84% of studies used U6 as the reference gene (100). However, the
584 expression of U6 was shown to vary with experimental conditions and disease, suggesting potential
585 limitations in its use as a universal housekeeping gene (101, 102). Other studies have shown that the ideal
586 housekeeping gene varies based on disease state and the biological fluid being studied, and mathematical
587 models such as geNorm, NormFinder, and BestKeeper should be used to identify a housekeeping gene
588 that is optimal for vitreous humor (100, 103). This holds particular significance as a gold standard

589 housekeeping gene would alleviate the challenge of small sample sizes in these studies, facilitating more
590 straightforward pooling of data.

591 One possible solution to the variability in the expression of housekeeping genes is the use of an
592 exogenous control. For example, cel-miR-39 -added to the vitreous samples- was used by several studies
593 reviewed here. Exogenous controls studies in the serum of cancer patients indeed showed less inter-
594 sample variability than endogenous controls (104). One drawback of exogenous controls, however, is that
595 because they are added in just prior to RNA isolation, they do not control for experimental variability that
596 occurs prior to this step (105). Other analysis strategies involve normalizing the expression of the target
597 gene to the rest of the genes within a microarray, either by averaging them, finding the median, or
598 identifying a few miRNAs that resemble the mean. While these strategies are mostly appropriate for high-
599 throughput studies with several hundreds of miRNAs, they have been shown to produce more accurate
600 results than reference genes in tumor samples (105, 106). One study, by Ando et al., used a housekeeping
601 gene, as well as the median expression level, to normalize the quantification of the target genes(86). Until
602 a standard housekeeping gene is identified and confirmed, normalization using a combination of
603 housekeeping genes and general average values may be the best approach.

604 Another barrier to building on the reviewed studies to identify clinically applicable biomarkers is
605 their validation, especially given their limited sample sizes. Two of the revised studies attempted to
606 strengthen their findings by concurrently studying miRNA in the serum of their subjects. However, the
607 two studies had opposing approaches. For example, Minezaki et al. found that miR-6513-3p, miR-138-2f-
608 3p and miR-4445-3p were elevated in vitreous and serum of PVRL patients as compared to uveitis patients,
609 but they did not compare the relative expression of miRNAs in vitreous vs serum for each patient (44). In
610 contrast, Hirota et al. reported an increase in the expression of miR-23a, miR-320a, and miR-320b in the
611 vitreous of PDR patients, as compared to the serum of the same PDR patients and as compared to vitreous
612 samples from controls (40). This suggests that upregulation of these miRNAs in PDR is an intraocular-

613 specific process, rather than a systemic one, providing new insights into PDR pathogenesis. The strategy
614 used by Minezaki et al., looking for a positive correlation between vitreous and serum miRNA levels, may
615 be more useful for validating biomarkers involved in systemic diseases. If successful, this approach can
616 lead to serum biopsies replacing vitreous altogether, while still providing data that is clinically relevant for
617 ocular and retinal diseases. The approach by Hirota et al. could be more useful for changes localized to
618 the eye. Beyond biomarker validation, results that are tissue-dependent can carry with them potential
619 mechanistic insights. Overall, there is currently little data to guide the interpretation of miRNA levels in
620 vitreous vs serum, and how these comparisons should affect the potential of miRNA as diagnostic
621 biomarkers.

622 Among the three most commonly dysregulated miRNAs in PDR, miR-142 emerged as consistently
623 upregulated and specific to PDR, presenting itself as a potential biomarker. However, while KEGG analysis
624 indicated pathway enrichments related to diabetes and diabetic retinopathy, further elucidation of miR-
625 142's role in the underlying pathology of PDR is necessary. On the other hand, miR-9 garnered substantial
626 evidence supporting its involvement in the pathogenesis of PDR, thereby enhancing its potential as a
627 biomarker. Notably, Liu et al. demonstrated elevated levels of miR-9 in exosomes derived from retinal
628 Muller cells, with miR-9 facilitating angiogenesis through the targeting of the S1P1/AKT/VEGFR2 pathway.
629 Moreover, miR-9's angiogenic effects via S1P1 targeting in tumor endothelial cells underscore its
630 significance (107). Additionally, KEGG analysis highlighted miR-9's involvement in the p53 and MAPK
631 pathways, both implicated in PDR pathogenesis (65, 66, 75). These findings collectively underscore miR-
632 9's potential as a crucial pathological indicator of PDR, notwithstanding its downregulation in the study
633 by Kot et al., which could be attributed to population differences or methodological disparities in miRNA
634 quantification.

635 Turning attention to PVRD, miR-21 emerged as dysregulated in four studies, with elevated levels
636 correlating with PVRD pathogenesis. For instance, Usui-Ouchi et al. demonstrated TGF- β -induced

637 upregulation of miR-21 expression in RPE cells, promoting RPE cell proliferation (81). Given the prominent
638 role of TGF- β in inflammation and cell proliferation, and its targeting in PDR treatment, the study suggests
639 a potential pathogenic role for miR-21 in diabetic retinopathy (108-110). Furthermore, miR-21-dependent
640 promotion of fibrosis in various contexts, suggests its contribution to the retinal fibrosis observed in PVRD
641 (111-113). Against the reported downregulation of miR-21 in the study by Toro et al., its consistent
642 upregulation in three other studies suggests potential isoform-specific differences contributing to this
643 discrepancy. Further confirmatory studies validating miR-21-5p upregulation in vitreous humor in PVRD
644 would be valuable, given the established role of miR-21 in retinal and systemic fibrosis, cementing its
645 emerging status as a pathological marker in PVRD.

646 In conclusion, it is important to acknowledge the limitations of the current analysis, notably the
647 small sample sizes in most studies, and the variability in methodologies for miRNA purification,
648 amplification, and quantification across studies. Additionally, the heterogeneous selection of control
649 groups, ranging from healthy individuals to those with minimal risk of disease progression, poses a
650 challenge to this emerging field. Nonetheless, our findings suggest that specific miRNA, including miR-142,
651 miR-9, and miR-21, hold promise as diagnostic tools for their respective diseases. Further research is
652 needed to validate and expand these findings and advance the clinical integration of miRNA as biomarkers
653 for retinal diseases.

923

924

925

926 **List of Abbreviations**

927 AMD – Age-related Macular Degeneration

928 ERM – Epiretinal Membrane

929 DR – Diabetic Retinopathy

930 MH – Macular Hole

931 miRNA - microRNA

932 NPDR – Non-Proliferative Diabetic Retinopathy

933 PDR - Proliferative Diabetic Retinopathy

934 PM – Pathological Myopia

935 PVR – Proliferative Vitreoretinopathy

936 PVRD - Proliferative vitreoretinal disease

937 PVRL – Primary Vitreoretinal Lymphoma

938 RD – Retinal Detachment

939 RRD – Rhegmatogenous Retinal Detachment

940

941 **Declarations**

942 **Ethics approval and consent to participate:** Not applicable

943 **Consent for publication:** Not applicable

944 **Availability of data and materials:** All data generated or analyzed during this study are included in this
945 published article, and its supplementary information files.

946 **Competing interests:** The authors declare that they have no competing interests.

947 **Funding:** This study was supported by Research to Prevent Blindness (RPB) Career Development Award to
948 MT and RPB Unrestricted Gift to the Flaum Eye Institute, University of Rochester Medical Center.

949 **Authors contributions:** DJ designed and conducted the research; collected and interpreted the data;
950 wrote the manuscript. BG assisted in manuscript writing and editing. MT conceptualized the study and
951 designed the research; assisted in data interpretation; wrote and edited the manuscript. All authors read
952 and approved the final manuscript.

953 **Acknowledgements:** Not applicable.
