14 Running title: Knowledge and Attitude of Emergency Physicians towards Palliative Care

15 **Funding:** This research received a grant from Kuwait Foundation for the Advancement of Sciences
16 (KFAS) under grant agreement no. P116-13NO-01.

17 **Authors' contributions:** Ameena Al-Ansari, Saleem Nawaf Suroor, Sobhi Mostafa AboSerea,
18 **Wafaa Mostafa AbdElGawad:** study concept, study design, acquisition of subjects and data,
19 interpretation of data, preparation of the manuscript. All authors had approved the final article.

20 **Competing interests:** The author(s) declared no potential conflicts of interest with respect to the
21 research, authorship and/or publication of this article.

22

23 **Background and Aim:** Although the challenges of integrating palliative care practices
24 across care settings are real and well recognized until now little is known about palliative
25 care practice of emergency physicians (EPs) and their accessibility to palliative care services
26 in Kuwait. So the aim of this study was to explore the attitude, and knowledge encountered
27 by EPs in providing palliative care in all general hospitals in Kuwait.

28 **Method:** A cross-sectional survey was performed in the emergency rooms of all general
29 hospitals in Kuwait using Palliative Care Attitude and Knowledge (PCAK) questionnaire.

30 **Results:** Of the total number of physicians working in emergency rooms (n=156), 104
31 (66.67%) had completed the survey. 76.9% (n=80) of the EPs had either uncertain attitude
32 toward palliative care. Most of the EPs (n=73, 70.28%) didn't discuss the need of the patients
33 to palliative care either with the patients or their families. Only 16 (15.4%) of the EPs
34 responded correctly to the most of the questions while nearly half of the EPs (n=51, 49%) had
35 poor knowledge especially in the most effective management of refractory dysnea (n=18,
36 17.3%). Experience \geq 11yrs and better knowledge scores were independent predictors of
37 positive attitude after adjustment of age, sex, qualifications, specialty, position, and
38 nationality [OR: 5.747 (CI: 1.031-25.00), 1.458(CI: 1.148-1.851); p-value: 0.021, 0.002
39 respectively]..

40 **Conclusions:** Despite recognizing palliative care as an important competence, the majority of
41 the emergency physicians in Kuwait had uncertain attitude and poor knowledge towards
42 palliative care. Lack of knowledge, direct accessibility to palliative care services and lack of
43 support from palliative medicine specialists were the main reasons for uncertain and negative
44 attitude. Efforts should be done to enhance physician training and provide palliative care
45 resources in order to improve the quality of care given to patients visiting emergency
46 departments.

48 **Keywords:** Palliative care, Palliative Care Attitude and Knowledge (PCKA), Emergency
49 physicians, opioids, Kuwait.

What this paper adds

- Studies proved that the emergency room may be a suitable place for early referral of patients who may benefit from palliative care especially old age to prevent upcoming undesired admissions and hospital deaths.
- The integration of palliative care concepts and consultation teams into emergency medicine may help to avoid unnecessary and burdensome treatments, tests, and procedures that are not aligned with patients' goals of care.
- Although the challenges of integrating palliative care practices across care settings are real and well recognized until now little is known about palliative care practice of emergency physicians and their accessibility to palliative care services in Kuwait.
- Recently, a newly developed tool called Palliative Care Attitude and Knowledge (PCKA) questionnaire was created to assess the attitude and knowledge of non-palliative physicians toward palliative care. So the aim of this study was to explore the attitude, and knowledge encountered by emergency physicians in providing palliative care using PCKA⁸ in emergency departments in all general
- Studies showed that early palliative care consultation was shown to improve quality of life for cancer patients and may even lengthen their survival.

57

58 **Introduction:**

59 Emergency medicine is a medical specialty that is concerned with stabilization of
60 patients with acute illness or injury for definitive care.¹ In this specialty, emergency
61 physicians are trained to provide acute treatments for emergency medical conditions aiming
62 at preserving patients' life regardless of their wellbeing.^{1,2}

63 While patients and their families under palliative care can experience stressful and
64 overwhelming moments during the disease trajectory such as sudden respiratory distress,
65 severe pain, vomiting, confusion and many other symptoms,³ the first point of access is often
66 the emergency room. Unfortunately, many of them die in the hospitals despite their wish to
67 die at home.⁴ Hospitals; where palliative medicine specialists are available; can provide the
68 opportunity for the patients and their families to establish their preferences for care and to
69 coordinate the aggressiveness of treatment, symptom management, and place of death.^{3,4}

70 Moreover, early palliative care consultation was shown to improve quality of life for
71 cancer patients and may even lengthen their survival.⁵ Most recently, studies proved that the
72 emergency room may be a suitable place for early referral of patients who may benefit from
73 palliative care⁶ especially old age to prevent upcoming undesired admissions and hospital
74 deaths.⁷

75 The integration of palliative care concepts and consultation teams into emergency
76 medicine may help to avoid unnecessary and burdensome treatments, tests, and procedures
77 that are not aligned with patients' goals of care.² Although the challenges of integrating
78 palliative care practices across care settings are real and well recognized until now little is known
79 about palliative care practice of emergency physicians and their accessibility to palliative care
80 services in Kuwait. Recently, a newly developed tool called Palliative Care Attitude and Knowledge
81 (PCKA) questionnaire was created to assess the attitude and knowledge of non-palliative physicians

82 toward palliative care.⁸ So the aim of this study was to explore the attitude, and knowledge
83 encountered by emergency physicians in providing palliative care using PCAK ⁸ in emergency
84 departments in all general hospitals in Kuwait.

85 **Method:**

86 **Study design and setting:**

87 A cross-sectional survey was performed in the emergency rooms of all general
88 hospitals under the Ministry of Health of Kuwait. This includes six general hospitals; Al-
89 Sabah, Al-Jahra, Al-Amiri, Al-Adan, Al-Farawanyia and Mubarak Al-Kabeer hospitals.

90 **Measurements and intervention:**

91 Palliative Care Attitude and Knowledge Questionnaire (PCKA):⁸

92 It is a newly developed questionnaire composed of three sections. Section one
93 includes demographic data such as age, sex, level of education, work experience, workplace,
94 medical subspecialty and palliative care experience. Section two is assessing the attitude and
95 formed of 11 items. The tool had a 5 point Likert scale ranging from strongly disagree (1) to
96 strongly agree (5). Negative or unfavorable attitude was considered if the participant scored
97 ≤ 25 , uncertain attitude if scored >25 but <41 , positive or favorable attitude if scored ≥ 41 .
98 The third section inquiries about knowledge. It includes 2 parts; the first part was about the
99 self-reported knowledge (3 questions) and the second part is 12 clinical questions. Regarding
100 self-knowledge, 5 points likert scale was used ranging from excellent response (5) to none
101 (1). Regarding basic knowledge scoring; Poor knowledge was calculated if participant scored
102 less than 50% of the total score (12 points) (≤ 5 points), fair knowledge if $\geq 50\%$ to $<75\%$
103 (6-9 points), good knowledge if scored $>75\%$ (≥ 10 points).⁸

104 **Selection of Participants:**

105 The questionnaires were distributed to all emergency physicians in all general
106 hospital in Kuwait (Figure 1) and recollectd back by hand to hand and revised within 48
107 hours. The flowchart of the sampling procedure was presented in Figure 1.

108 **Ethical statement:**

109 The approval of the Institutional Review Board (IRB) of the Ministry of Health
110 was taken prior to the study (No.210/2016, March 2016). Informed consent was obtained
111 from all participants. Participants' anonymity and confidentiality were kept throughout all
112 phases of the study. Approvals were also obtained from participating emergency departments
113 of all general hospitals.

114 **Statistical analysis:**

115 All data manipulation and analysis were performed using the SPSS (Statistical
116 Package for Social Science) SPSS version 20. P-values less than 0.05 were regarded as a sign
117 of statistical significance. Independent sample t-test was used for comparison between
118 quantitative data. Chi-square test or Fisher's Exact when appropriate were used to compare
119 between qualitative variables. Generalized linear method was used to find out the
120 independent predictors of positive attitude toward palliative care with adjustment of any
121 confounding factors. We used the consolidated criteria for reporting observational studies
122 (RECORD) checklist as far as this was applicable to our study.

123 **Results:**

124 **Characteristics of study subjects:**

125 Of the total number of physicians working in emergency rooms in Kuwait (n=156
126 physicians), 19 physicians were on annual leave and 11 physicians refused to participate. The
127 remaining 126 emergency physicians who responded to the questionnaire, 104 (82.54%) had
128 completed the survey in all general hospitals. (Figure1). The number of participants was 15
129 (14.2%) from AlSabah hospital, 20 (19.2%) from Al-Amiri hospital, 18 (20%) from Mubarak
130 Al-Kabeer hospital, 20 (17.33%) from Al-Farawanyia hospital, 14 (13.5%) from Al-Adan
131 hospital and 17 (20.44%) from Al-Jahrah hospital. (Figure 1).

132 86.6% (n=90) were males and 13.5% (n=14) were females and mean age of the
133 respondents was 38.83±9.5 years old. The median years of experience were 11 (IQR: 7-13)
134 years. Due to the diversity of population demographics, only 20.19% (n=21) were Kuwaiti
135 physicians. Most of respondents had postgraduate emergency medicine studies (n=68;
136 65.4%), followed by internal medicine studies (12; 11.5%). (Table 1).

137 **Main results:**

138 Only 18.3% (n=19) of the emergency physicians had a favorable attitude towards
139 palliative care. Most of them had uncertain attitude (76.9%, n=80) and 4.8% (n=5) had an
140 unfavorable attitude. Most of them agreed about the need of all adults and children who are
141 terminally ill for palliative care services, not just those with cancer (Q7: n =65; 62.5%) and
142 approved also that palliative care benefits include enhanced quality of life for the patient and
143 family (Q9:n=81; 77.9%), skilled care for terminally ill patients (Q10: n=82; 78.8%), and
144 expert pain and symptom management (Q11: n=85; 81.7%). Unfortunately, they emphasized
145 onthe lack of timely communication between palliative care providers and themselves (Q2:
146 n=71; 68.3%). Many of them dissatisfied with palliative care services in the past (Q1: n=61;
147 58.7%), reported unfamiliarity with the currently available palliative care services (Q3: n=65;
148 62.5%), and its types (Q5:n=54; 51.9%). Moreover, the uncertainty about its length of

149 coverage was 53.8% (Q4: n=56). Generally, the emergency physicians with experience ≥ 11
150 years had statistically significant better attitude scores than the emergency physicians with
151 experience < 11 (p value=0.019, Figure 2) but in most of the individualized items of the
152 attitude, no statistically significant between them.

153 Most of the emergency physicians (n=73, 70.28%) didn't discuss the need of the
154 patients to palliative care either with the patients or their families. 44 (42.3%) of them
155 reported no or little knowledge in pain assessment and management, while 58 (55.8%) and 41
156 (39.4%) reported good knowledge in other symptoms assessment and management, and the
157 counseling respectively. Neither years of experience nor nationality had any statically
158 significant effect on self-assessment of their knowledge and experience of the emergency
159 physicians towards palliative care. (Table 1).

160 The overall percentage of the emergency physicians that responded correctly to the
161 most of the questions about the basic knowledge of palliative care was only 16 (15.4%) while
162 37 (35.6%) had a fair knowledge and unfortunately many of them (n=51; 49%) responded to
163 $> 50\%$ of the questions incorrectly. The median number of total corrected answers was 6
164 (IQR: 4-8) out of 12. Surprisingly, none of the emergency physicians answered all the
165 questions correctly. An overview of the questions and their answers was presented in Table 3.
166 Q11 for the symptoms of cord compression was the one with the highest percentage of
167 correct answers (Q11: n=94; 90.4%) while Q8 about the most effective treatment for the
168 refractory dyspnea question had the lowest rate of correct answers (Q8:n=18;17.3%). They
169 had mostly poor to fair knowledge regarding opioids handling; such as types of opioids
170 (Q3:n=57;54.8%), World Health Organization ladder for pain management (Q7:
171 n=39;37.5%), opioids toxicity (Q8:n=31; 29.8%), use of oral opioids (Q15:n=19; 18.3%); and

172 delirium (Q4:n=62; 59.65%) and management of catastrophic bleeding in palliative setting
173 (Q10:n=20; 19.2%).

174 Most of the emergency physicians had good knowledge scores regarding the
175 differences between traditional and palliative care (Q1: n=79; 76%) and the multidisciplinary
176 team role in palliative care (Q2:n=83; 79.8%). No statistically significant differences between
177 years of experience of the emergency physicians and their knowledge scores (Figure 3) in
178 most of the questions except palliative care definitions and signs of opioid toxicity in which
179 the emergency physicians with less experience answered significantly better (86% vs 66.7%,
180 40% vs 20.4%; p-value: 0.024, 0.029 respectively) while in diagnosis of superior venous
181 obstruction, the emergency physicians with more years of experience answered better (12%
182 vs 35.2%; p-value: 0.011). No statistically significant differences between the emergency
183 physicians from different hospitals in the attitude or knowledge scores or demographic
184 characteristics. (Table 4).

185 By using generalized linear method to find out the independent predictors of positive
186 attitude toward palliative care, we found that years of experience ≥ 11 yrs and better
187 knowledge scores were independent predictors of positive attitude after adjustment of age,
188 sex, qualifications, specialty, position, and nationality [OR: 5.747 (CI: 1.031-25.00),
189 1.458(CI: 1.148-1.851); p-value: 0.021, 0.002 respectively]. (Table 5)

190 **Discussion**

191 To the best of our knowledge, this is the first survey of its kind conducted in Kuwait
192 to evaluate palliative care attitude and knowledge targeting the emergency physicians
193 anywhere in the entire region. We used PCAK which is a newly developed validated and
194 reliable tool⁸ to assess the attitude and knowledge among physicians. There are more than
195 150 physicians working in the emergency rooms in 6 hospitals distributed all over Kuwait.

196 Most of them had uncertain attitude and poor knowledge scores. Better knowledge scores and
197 experience ≥ 11 yrs were positive predictors of favorable attitude. Although more than 10
198 different nationalities are existing in Kuwait like Egyptians, Syrians, Pakistanis, Indians, and
199 others from different cultures, emergency rooms demographic, medical education, specialties,
200 years of experience but no statically significant differences between them in their knowledge
201 or attitude toward palliative care. This differed from many studies which reported that
202 clinician attitudes or knowledge were affected by nationality, physicians' position, staff type,
203 years of experience, emergency rooms demographic and hospital type.⁹

204 In our study, 76.9% of the emergency physicians had either uncertain attitude toward
205 palliative care while only 18.3% had a favorable or positive attitude. This was mainly due to
206 either dissatisfaction about PC services, types, accessibility, length of coverage and lastly
207 lack of timely communication between them and palliative care providers as reported in our
208 study. These results is similar to the original results of PCAK questionnaire.⁸ Many factors
209 affecting the attitude of the emergency physicians depending on their diverse experiences,
210 which ranged from positive, encouraging to a negative and distressing expierence.^{9,10} This
211 includes sometimes a sense of incompetence to alter the course of the disease^{3, 11} or feeling
212 anxious and uncomfortable about discussing death and dying with the terminally ill
213 patient.^{12,13} This negative attitude can hinder the quality of care provision especially at the
214 end of life.

215 Most of the emergency physicians (n=73, 70.28%) didn't discuss the need to
216 palliative care either with the patients or their families. The willingness to engage in end-of-
217 life discussions becomes key to improve palliative care in the emergency department.^{14, 15}
218 However, palliative care referrals remain largely underutilized in all areas of healthcare and
219 are characteristically initiated late in the disease trajectory.^{16,17} Furthermore, most of the

220 emergency physicians feel that it is not their obligation to discuss the need for palliative care
221 and they feel that the family physicians or the oncologists are the one who is responsible
222 about this discussion.^{3,18}

223 Nearly half of the emergency physicians (49%) had poor knowledge. Although many
224 of them subjectively reported good knowledge in counseling and other symptoms (rather than
225 pain) assessment and management and they strongly agreed that palliative care is an
226 important competence for emergency physicians^{3,18} but it wasn't necessarily reflected in their
227 effectiveness of care especially in view of their poor knowledge at most. These results is
228 similar to the original results of PCAK questionnaire.⁸

229 They had mostly poor knowledge in opioids handling, delirium and management of
230 catastrophic bleeding in the palliative setting. This is similar to many studies that reported a
231 lack of knowledge in palliative care, especially pain management proficiency.¹⁸⁻²⁰

232 The setting of emergency rooms; as crowded spaces, noisy environment,
233 compromised privacy, frequent interruptions, time constraints, illness complexity, and
234 medico-legal threats;^{21,22} make the initiation of palliative care discussions less than ideal in
235 these settings.^{3,22} Unfortunately, being not confident with the diagnosis and concerns of
236 diminishing patients' or families' hope, or believing that patients are not prepared to hear
237 forthcoming information make physicians often hesitate to discuss patients prognosis either
238 with the patients or their families.²² Subsequently, aggressive interventions often initiated
239 may ultimately be misaligned with overall goals of care although retrospectively viewed as
240 futile, harmful, and painful.²³ In reality, the culture of emergency setting that provides
241 stabilization of acute medical emergencies was sometimes at odds with the culture of
242 palliative care, which balances quality of life with the burdens of invasive treatments.^{2,18}

243 In our study, good knowledge was positively associated with the positive attitude of
244 the emergency physicians toward palliative care. This was agreed with Thulesius et al. who
245 revealed that good knowledge of staff significantly improved attitudes toward the end of life
246 care and the authors suggested initiatives to educate physicians working in ED's will help
247 them to change their negative attitudes and contribute better quality of patient care.²⁴

248 Many studies reported a significant correlation between the level of knowledge and
249 attitudes towards palliative care. This is highlighting that as participants' level of knowledge
250 increased, attitudes become more positive in hospitals such as in Lebanon,²⁵ Ethiopia,²⁶
251 Saudi Arabia,²⁷ and India.²⁸ As a part of human nature, the degree and complexity of their
252 knowledge affect their attitudes and in turn their behavior.²⁹

253 The effective measurement of knowledge and attitude of the physicians is an important
254 component of the evaluation of education and practice especially if used prior to any
255 educational activity or program. This would result in more willingness to contribute in
256 discussion and generate greater receptivity to the educational materials.^{30,31} Again it can be
257 applied post activity to document the change in their knowledge and attitude and at the same
258 time to evaluate the efficiency of the training and educational program.

259 Strength and limitation of the study:

260 It is the first study to assess the knowledge and attitude of the emergency physicians
261 toward palliative care in the entire region. All the emergency physicians in Kuwait were
262 involved in the research with no selection bias. The scarcity of similar studies carried out in
263 Kuwait, Eastern Mediterranean region and in other parts of the world made the comparison
264 and discussion difficult. Palliative care is recently introduced in Kuwait and it is still in the
265 phase of development with the shortage of the number of the available palliative medicine
266 specialists, this may explain the uncertain or the negative attitude towards palliative care.

267 Despite recognizing palliative care as an important competence, the majority of the
268 emergency physicians in Kuwait had uncertain attitude and poor knowledge towards
269 palliative care. Lack of knowledge, direct accessibility to palliative care services and lack of
270 support from palliative medicine specialists were the main reasons for uncertain and negative
271 attitude.

272 **Conclusion:**

273 Despite recognizing palliative care as an important competence, the majority of the
274 emergency physicians in Kuwait had uncertain attitude and poor knowledge towards
275 palliative care. Lack of knowledge, direct accessibility to palliative care services and lack of
276 support from palliative medicine specialists were the main reasons for uncertain and negative
277 attitude. Efforts should be done to enhance physician training and provide palliative care
278 resources in order to improve the quality of care given to patients visiting emergency
279 departments. Attention should be given to palliative care by the national health policy. There
280 is an urgent need to be incorporated into the national curriculum of medical students and the
281 emergency physicians' education. Further efforts are needed to push the palliative care across
282 different healthcare sectors.

283 **Ethics approval and consent to participate:** The research project has been approved by the
284 Institutional Review Board (IRB) of the Ministry of Health, Kuwait (No.210/2016, March
285 2016) within which the work was undertaken and that it conforms to the provisions of the
286 Declaration of Helsinki. All subjects gave informed consent and their anonymity was
287 preserved.

288 **Consent for publication:** not applicable.

289 **Availability of data and materials:** The datasets generated during and/or analyzed during
290 the current study are available from the corresponding author on reasonable request.

291 **Competing interests:** The author(s) declared no potential conflicts of interest with respect to
292 the research, authorship and/or publication of this article.

293 **Funding:** This research received a grant from Kuwait Foundation for the Advancement of
294 Sciences (KFAS) under grant agreement no. P116-13NO-01.

295 **Authors' contributions: Ameena Al-Ansari, Saleem Nawaf Suroor, Sobhi Mostafa**
296 **AboSerea, Wafaa Mostafa AbdeIGawad:** study concept, study design, acquisition of
297 subjects and data, interpretation of data, preparation of the manuscript. All authors had
298 approved the final article.

299 **Acknowledgements**

300 The authors would like to thank all the participants for their valuable contributions to this
