11 **Abstract**

12 **Background:** Electroencephalography-based brain-computer interfaces (BCI) that allow the
13 control of robotic devices to support stroke patients during upper limb rehabilitation are
14 increasingly popular. Hand rehabilitation is focused on improving dexterity and fine motor
15 control and is a core approach for helping stroke survivors regain activities of daily living.
16 This systematic review examines recent developments in BCI-robotic systems for hand
17 rehabilitation and identifies evidence-based clinical studies on stroke patients.

18 **Methods:** A search for January 2010-October 2019 articles using Ovid MEDLINE, Embase,
19 PEDro, PsycINFO, IEEE Xplore and Cochrane Library databases was performed. The
20 selection criteria included BCI-hand robotic systems for rehabilitation in various
21 development stages involving tests on healthy human subjects or stroke survivors. Data fields
22 include those related to study design, participant characteristics, technical specifications of
23 the system, and clinical outcome measures.

24 **Results:** 30 studies were identified as eligible for qualitative review and among these, 11
25 studies involved testing a BCI-hand robot on chronic and subacute stroke patients.
26 Statistically significant improvements in motor assessment scores relative to controls were
27 observed for two BCI-hand robot interventions. The degree of robot control for the majority
28 of studies was limited to triggering the device to perform grasping or pinching movements
29 using motor imagery. Most employed a combination of kinaesthetic and visual response via
30 the robotic device and display screen, respectively, to match feedback to motor imagery.

31 **Conclusion:** Most studies on BCI-robotic systems for hand rehabilitation report systems at
32 prototype or pre-clinical stages of development. Some studies report statistically significant
33 improvements in functional recovery after stroke, but there is a need to develop a standard
34 protocol for assessing technical and clinical outcomes so that the necessary evidence base on
35 efficiency and efficacy can be developed.

38 observation, robot-assisted rehabilitation, hand, wrist, stroke, therapy

39

40 **Background**

41 There is growing interest in the use of robotics within the field of rehabilitation. This interest
42 is driven by the increasing number of people requiring rehabilitation following problems such

43 as stroke (with an ageing population), and the global phenomenon of insufficient numbers of
44 therapists able to deliver rehabilitation exercises to patients [1,2]. Robotic systems allow a

45 therapist to prescribe exercises that can then be guided by the robot rather than the therapist.

46 An important principle within the use of such systems is that the robots assist the patient to
47 actively undertake a prescribed movement rather than the patient's limb being moved

48 passively. This means that it is necessary for the system to sense when the patient is trying to
49 generate the required movement (given that, by definition, the patient normally struggles with

50 the action). One potential solution to this issue is to use force sensors that can detect when the
51 patient is starting to generate the movement (at which point the robot's motors can provide

52 assistive forces). It is also possible to use measures of muscle activation (EMGs) to detect the
53 intent to move [3]. There is, however, growing interest in the potential of using measures of

54 brain activity to identify when a patient is trying to generate a movement- referred to as Brain
55 Computer Interfaces, or BCIs. This interest in BCIs is motivated by idea that the

56 rehabilitation process can be enhanced by particular types of brain activity related to

57 imagining the movement [4]. There is a long history of using robotic devices for stroke

58 rehabilitation [5,6] and in the last decade, there has been a concerted effort by groups of

59 clinicians, neuroscientists and engineers to integrate these systems with incoming brain

60 signals to enhance the efficacy and effectiveness of stroke rehabilitation. The purpose of this

61 manuscript is to review the current state-of-the-art of existing brain-computer ‘closed loop’
62 interfaces in terms of the technological readiness of existing systems, and the evidence for
63 their clinical effectiveness.

64

65 BCIs allow brain state-dependent control of robotic devices to aid stroke patients during
66 upper limb therapy and have been gaining research attention since their first implementation
67 more than a decade ago [7,8]. Graimann et al. [4] defined a BCI as an artificial system that
68 provides direct communication between the brain and a device based on the user’s intent;
69 bypassing the normal efferent pathways of the body’s peripheral nervous system. A BCI
70 recognises user intent by measuring brain activity and translating it into executable
71 commands usually performed by a computer, hence the term “brain-computer interface”.

72

73 Most robotic devices used in upper limb rehabilitation exist in the form of exoskeletons or
74 end-effectors. Robotic exoskeletons (i.e., powered orthoses, braces) are wearable devices
75 where the actuators are biomechanically aligned with the wearer’s joints and linkages;
76 allowing the additional torque to provide assistance, augmentation and even resistance during
77 training [9]. In comparison, end-effector systems generate movement through applying forces
78 to the most distal segment of the extremity via handles and attachments [9]. Rehabilitation
79 robots are classified as Class II-B medical devices (i.e., a therapeutic device that administers
80 the exchange of energy, mechanically, to a patient) and safety considerations are important
81 during development [10,11]. Most commercial robots are focused on arms and legs, each
82 offering a unique therapy methodology. There is also a category of device that target the hand
83 and finger. Hand and finger rehabilitation are core component in regaining activities of daily
84 living (ADL) as many ADLs require dexterous and fine motor movements (e.g. grasping and

85 pinching). Thus, the current review is focused on devices that have been designed specifically
86 for wrist, hand and finger rehabilitation.

87

88 The potential of BCIs has gained considerable attraction because the neural activity involved
89 in the control of the robotic device may be a key component in the rehabilitation itself. For
90 example, mental rehearsal of movement is thought to activate some of the neural networks
91 involved in movement execution (ME) [12–15]. The resulting rationale is that encouraging
92 the use of motor imagery (MI) (i.e., the imagination of movement without execution) could
93 increase the capacity of the motor cortex to control major muscle movements and decrease
94 the necessity to use neural circuits damaged post-stroke. The scientific justification for this
95 approach was first provided by Jeannerod [15] who suggested that the neural substrates of MI
96 are part of a shared network that is also activated during the simulation of action by the
97 observation of action (AO) [15]. These ‘mirror neuron’ systems are thought to be an
98 important component of motor control and learning [15] - hence the belief that stimulating
99 these systems could aid rehabilitation.

100

101 A recent meta-analysis of the neural correlates of action (MI, AO and ME) quantified
102 ‘conjunct’ and ‘contrast’ networks in the cortical and subcortical regions [12]. This analysis,
103 which took advantage of open-source historical data from fMRI studies, reported consistent
104 activation in the premotor, parietal and somatosensory areas for MI, AO and ME. Predicated
105 on such data, researchers have reasoned that stimulating MI should cause activation of the
106 neural substrates that are also involved in controlling movement and there have been a
107 number of research projects that have used AO in combination with MI in neurorehabilitation
108 [16–18] and motor learning studies [19,20] over the last decade.

109

110 The strategy of BCI-robot systems in rehabilitation is to recognise the patient's intention to
111 move or perform a task via an electroencephalography acquisition system [21], and then use
112 the robotic device to provide assistive forces in a manner that mimics the actions of a
113 therapist during standard therapy sessions [22]. The resulting feedback is patient-driven and
114 is designed to aid in closing the neural loop from intention to execution. This process is said
115 to promote use-dependent neuroplasticity within intact brain regions and relies on the
116 repeated experience of initiating and achieving a specified target [23,24]; making the active
117 participation of the patient in performing the therapy exercises an integral part of the motor
118 re-learning process [25,26]. It is important to note that whilst the rationale underpinning the
119 conjecture that BCI-robot systems could be useful in hand rehabilitation is reasonable, it is
120 just a conjecture that requires empirical support.

121
122 Electroencephalography (EEG) is currently the instrument of choice for data acquisition in
123 BCI systems because it is non-invasive, easy to use and can detect relevant brain activity with
124 high temporal resolution [27,28]. In principle, the recognition of MI activity via EEG can
125 allow the control of a device independent of muscle activity [4]. It has been shown that MI-
126 based BCI can discriminate motor intent by detecting event-related spectral perturbations
127 (ERSP) [21,29] and/or event-related desynchronisation/synchronisation (ERD/ERS) patterns
128 in the μ (9-11 Hz) and β (14-30 Hz) sensorimotor rhythm of EEG signals [29]. However,
129 EEG also brings with it some challenges- these neural markers are often concealed by various
130 artefacts and may be difficult to recognise through the raw EEG signal alone. Thus, signal
131 processing (via feature extraction and classification) is a vital part of obtaining a good MI
132 signal for robotic control.

133

134 One implication of using MI and AO to justify the use of BCI approaches is that great care
135 must be taken with regard to the quality of the environment in which the rehabilitation takes
136 place. An important feature of MI is that, by definition, the patient must be able to imagine
137 the movement. Likewise, AO requires the patients to clearly see the action. This suggests that
138 the richness and vividness of the visual cues provided is an essential part of an effective BCI
139 system. It is also reasonable to assume that feedback is important within these processes and
140 thus the quality of feedback should be considered as essential. Finally, motivation is known
141 to play an important role in promoting active participation during therapy [26,30]. Thus, a
142 good BCI system should incorporate an approach (such as gaming and positive reward) that
143 increases motivation. Recent advances in technology make it far easier to create a
144 rehabilitation environment that provides rich vivid cues, gives salient feedback and is
145 motivating. For example, the rise of immersive technologies, including virtual reality (VR)
146 and augmented reality (AR) platforms [31,30,32], allows for the creation of engaging visual
147 experiences that have the potential to improve a patient's self-efficacy [33] and thereby
148 encourage the patient to maintain the rehabilitation regime. One specific example of this is
149 visually amplifying the movement made by a patient when the movement is of limited extent
150 so that the patient can see their efforts are producing results [34].

151

152 In this article, we review the development of BCI-robotic systems for hand rehabilitation and
153 capture clinical studies involving stroke patients. Our goal was to address three critical
154 questions for understanding the current value and potential of BCI-based robotic therapy:

155

156 (1) Identify how BCI technologies are being utilised in controlling robotic devices for
157 hand rehabilitation. Our focus was on the study design and the tasks that are
158 employed in setting up a BCI-hand robot therapy protocol.

159 (2) Document the state-of-art of BCI systems. Because BCI for rehabilitation is still an
160 emerging field of research, we expected that most studies would be in their proof-of-
161 concept or clinical testing stages of development. Our purpose was to determine the
162 limits of this technology in terms of: (a) resolution of hand MI detection and (b) the
163 degree of which we can have robotic control.

164 (3) Evaluate the clinical significance of BCI-hand robot systems by looking at the
165 outcome measures in motor recovery and determine if a standard protocol exists for
166 these interventions.

167

168 It is important to note that there have been several recent reviews exploring BCI for stroke
169 rehabilitation. For example, Monge-Pereira et al. [35] compiled EEG-based BCI studies for
170 upper limb stroke rehabilitation. Their systematic review (involving 13 clinical studies on
171 stroke and hemiplegic patients) reported on research methodological quality and
172 improvements in the motor abilities of stroke patients. Cervera et al. [36] performed a meta-
173 analysis on the clinical effectiveness of BCI-based stroke therapy among 9 randomised
174 clinical trials (RCT). McConnell et al. [37] reviewed and provided insights from a total of
175 110 robotic devices with brain-machine interfaces for hand rehabilitation post-stroke. These
176 reviews, in general, have reported that such systems provide improvements in both functional
177 and clinical outcomes in pilot studies or trials involving small sample sizes. Thus, the
178 literature indicates that EEG-based BCI are a promising general approach for rehabilitation
179 post-stroke.

180

181 The current work complements these previous reports by focusing on a systematic review of
182 the rehabilitation of the fine motor skills associated with hand movement, and profiling BCI-
183 robot systems for the hands with their corresponding technical and clinical implementations.

184 **Methods**

185 **Protocol Registration**

186 Details of the protocol for this systematic review were registered on the International
187 Prospective Register of Systematic Reviews (PROSPERO) and can be accessed at
188 www.crd.york.ac.uk/PROSPERO (ID: CRD42018112107).

189

190 **Search Strategy and Eligibility**

191 An in-depth search of articles from January 2010 to October 2019 was performed on Ovid
192 MEDLINE, Embase, PEDro, PsycINFO, IEEE Xplore and Cochrane Library. Only full-text
193 articles published in English were selected for this review. Table 1 shows the combination of
194 keywords used in the literature searching.

195

196

Table 1. Keyword Combinations

Set 1 (OR)		Set 2 (OR)		Set 3 (OR)
Brain-computer interface/BCI		Stroke (rehabilitation/		Robotic (exoskeleton/
Electroencephalography/EEG		therapy/treatment/recovery)		orthosis)
Brain-machine interface/BMI		Motor (rehabilitation,		Powered (exoskeleton/
Neural control interface	AND	therapy/treatment/recovery)	AND	orthosis)
Mind-machine interface		Neurorehabilitation		Robot
		Neurotherapy		Device
		Hand (rehabilitation/therapy/		
		recovery/exercises/movement)		

197

198 The inclusion criteria for the articles were: (1) publications that reported the development of
199 an EEG-based BCI; (2) studies targeted towards the rehabilitation of the hand after stroke; (3)
200 studies that involved the use of BCI and a robotic device (e.g., exoskeleton, end-effector type,
201 platform-types, etc.); (4) studies that performed a pilot test on healthy human subjects or a
202 clinical trial with stroke patients. The articles were also screened for the following exclusion

203 criteria: (1) studies that targeted neurological diseases other than stroke; (2) studies that used
204 other intention sensing mechanisms (electromyography/EMG, electrooculography/EOG, non-
205 paretic hand, other body parts, etc.).

206

207 Two authors performed independent screenings of titles and abstracts based on the inclusion
208 and exclusion criteria. The use of a third reviewer was planned a priori in cases where a lack
209 of consensus existed around eligibility. However, consensus was achieved from the first two
210 authors during this stage. Full-text articles were then obtained, and a second screening was
211 performed until a final list of studies was agreed to be included for data extraction.

212

213 **Data Extraction**

214 The general characteristics of the study and their corresponding results were extracted from
215 the full-text articles by the reviewers following the Preferred Reporting Items for Systematic
216 Reviews and Meta-Analysis (PRISMA) checklist. Data fields included those related to study
217 design, participant characteristics, technical specifications of the system, and technical and
218 experimental results. For studies involving stroke patients, clinical outcomes were obtained
219 based on muscle improvement measures such as Fugl-Meyer Motor Assessment (FMMA)
220 scores [38], Action Research Arm Test (ARAT) scores [39], United Kingdom Medical
221 Research Council (UK-MRC) muscle grade [40], Grip Strength (GS) Test and Pinch Strength
222 (PS) Test scores (i.e., kilogram force collected using an electronic hand dynamometer)
223 among others.

224 **Quality Assessment**

225 *Technological Readiness*

226 We first assessed the development stages of the systems used in the studies extracted. By
227 performing a Technological Readiness Assessment (TRA), we were able to determine the
228 maturity of the systems via a Technology Readiness Level (TRL) scale of 1-9 and quantify its
229 implementation in a research or clinical setting. Since a BCI-robot for rehabilitation can be
230 categorised as a Class II-B medical device we have adapted a customised TRL scale to
231 account for these requirements [41].

232

233 *Clinical Use*

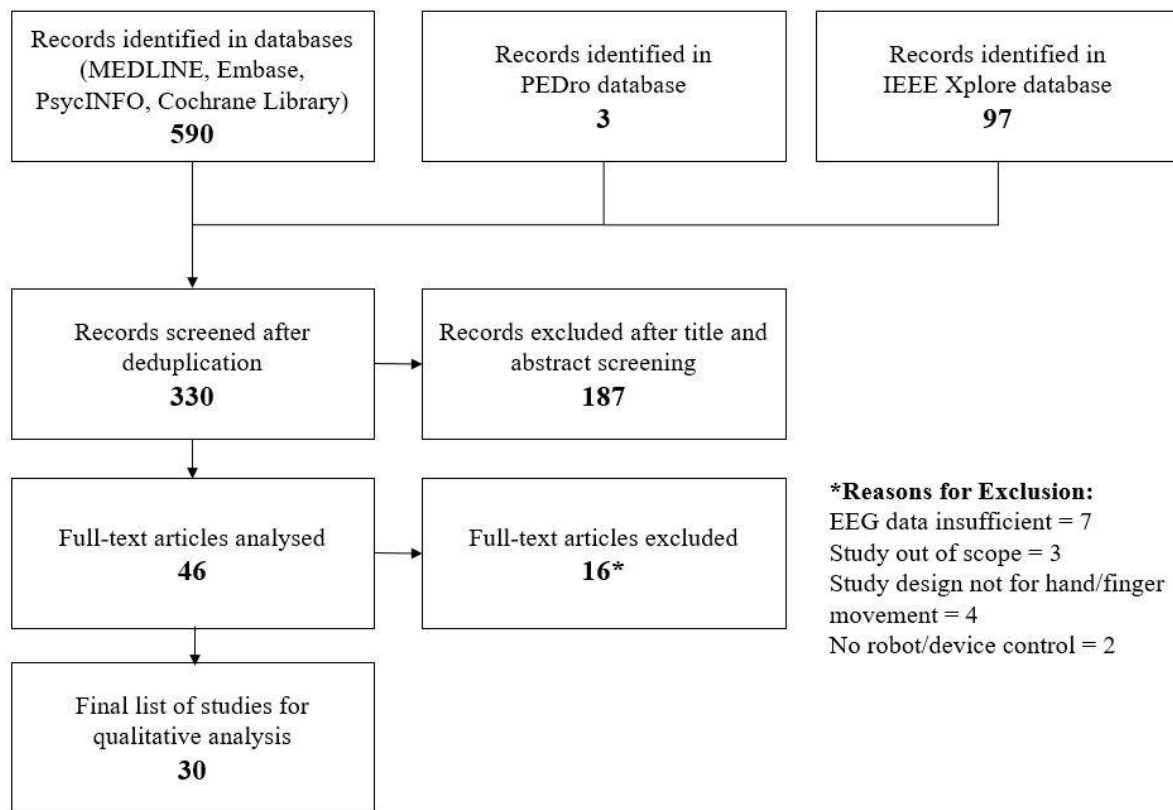

234 A methodological quality assessment was also performed for clinical studies based on the
235 Physiotherapy Evidence Database (PEDro) Scale [42]. This scale evaluates studies with a
236 checklist of 11 items based on experts' consensus criteria in physiotherapy practice. The
237 complete details of the criteria can be found online [43]. A higher score in the PEDro scale (6
238 and above) implied better methodological quality but are not used as a measure of validity in
239 terms of clinical outcomes. Pre-defined scores from this scale were already present in studies
240 appearing in the PEDro search. However, studies without PEDro scores or are not present in
241 the PEDro database at all had to be manually evaluated by the authors against the 11-item
242 checklist (five of seven studies).

243 Results

244 Search Results

245 Figure 1 shows the study selection process and the number of articles obtained at each stage.

246

247

248 **Figure 1. Study Selection Flowchart**

249

250 A total of 590 studies were initially identified. After deduplication, 330 studies underwent
251 title and abstract screening. Forty six studies passed this stage and among these, 16 were
252 removed after full-text screening due to the following reasons: insufficient EEG and robotic
253 data [44–50], the study was out of scope [51–53], the study design was not for hand/finger
254 movement [54–57], no robot or mechatronic device was involved in the study [58,59]. A final
255 list with 30 studies was identified as eligible for qualitative review. Among the 30 studies, 11
256 [60–70] were involved in testing the BCI-hand robot system on chronic and subacute stroke

257 patients ([60,65] are RCTs) while the rest involved testing on healthy participants [71–89].

258 Table 2 shows a summary of the relevant data fields extracted from these studies.

259

260 **[Table 2 Around Here]**

261

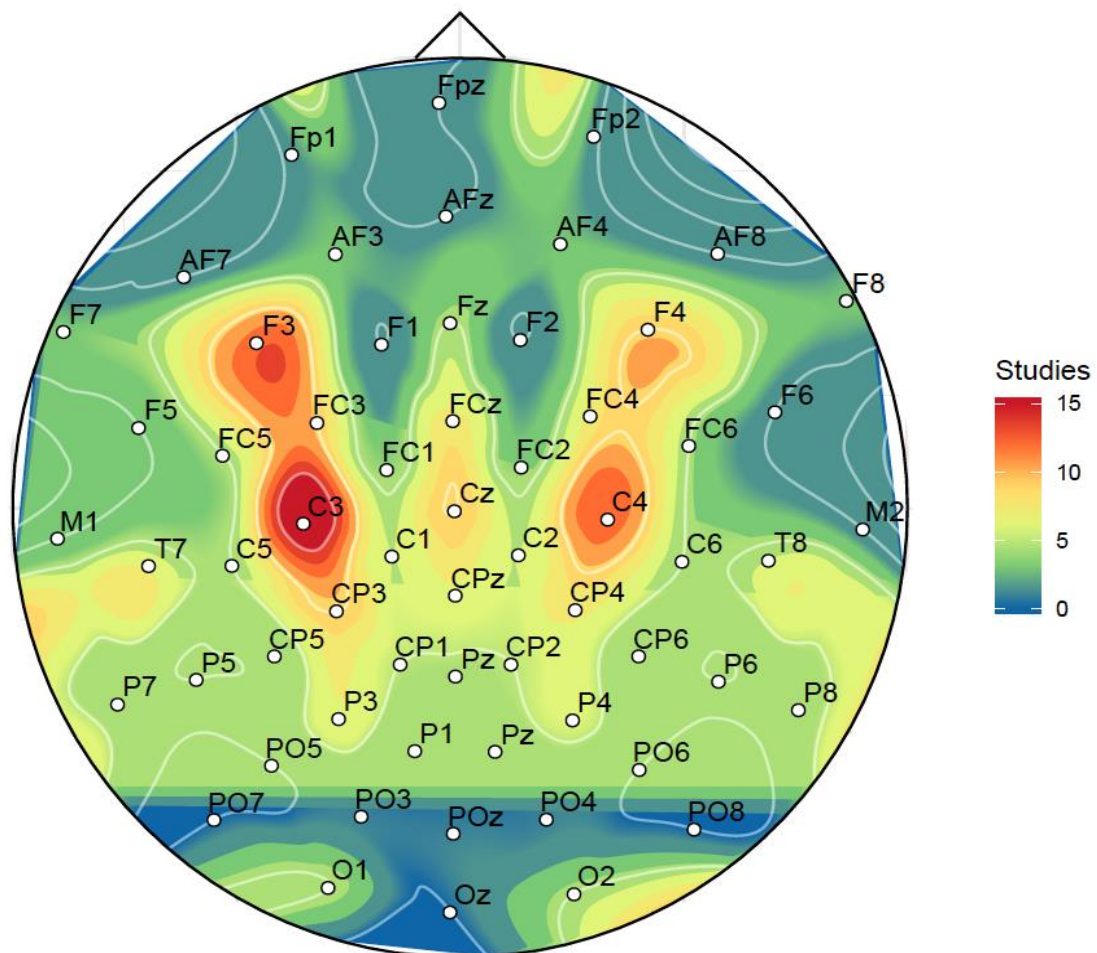

262 **Technology Evaluation**

263 *EEG Acquisition*

264 The choice of EEG system as well as the type of electrodes provides a technical trade-off and
265 affects the session both in terms of subjective experiences (i.e., ease-of-use, preparation time,
266 cleaning, comfortability) and data performance. Due to the presence of a conducting
267 gel/solution, standard “wet” electrodes provide a degree of confidence in preventing signal
268 disruption within a short duration usually enough for a standard stroke therapy session.
269 However, this also makes the setup, use and cleaning in the experiment more challenging, non-
270 ambulatory and reliant on a specialised laboratory setup [4]. Conversely, dry electrodes offer
271 an accessible, user-friendly and portable alternative by using dry metal pins or coatings that
272 comb through hair and come in contact directly with the scalp. The signal fidelity of dry
273 electrodes is still a matter of debate in the BCI community. A systematic comparison between
274 dry passively-amplified and wet actively-amplified electrodes reported similar performance in
275 the detection of event-related potentials (ERP) [90]. However, for a study involving dry active
276 electrodes [91], high inter-electrode impedance resulted in increased single-trial and average
277 noise levels as compared to both active and passive wet electrodes. In classifying MI,
278 movement-related artefacts adversely affect active dry electrodes, but these can be addressed
279 through a hybrid system of other physiological sensors to separate sources [92].

280

281 The EEG acquisition systems involved in the studies ranged from low-cost devices having few
282 electrode channels (2-15 gel or saline-soaked silver/silver chloride [Ag/AgCl] electrodes) to
283 standard EEG caps that had higher spatial resolution (16-256 gel or saline-soaked Ag/AgCl
284 electrodes). The placement of EEG channels was accounted for by studies involving MI
285 (N=21). This allowed us to determine the usage frequency among electrodes and is presented
286 in Figure 2 as a heat map generated in R Studio (using the packages: “akima”, “ggplot2” and
287 “reshape2”) against the 10-20 international electrode placement system.
288

289
290 **Figure 2. EEG Channel Usage across Motor Imagery Studies (N=21)**
291

292 It can be seen that the EEG channels used for MI studies are concentrated towards electrodes
293 along the central sulcus (C) region and the frontal lobe (F) region of the placement system
294 where the motor cortex strip lies. Among these, C3 (N=17) and F3 (N=14) were mostly used,
295 presumably because a majority of the participants were right-handed. The next most frequent
296 were C4 (N=13) and the electrodes F4, Cz and CP3 (N=10).

297

298 *Signal Processing: Feature Extraction and Classification*

299 It is necessary to process EEG data if they are to be used as a control signal. First, the data
300 need to undergo a series of pre-processing routines (e.g., filtering and artefact removal)

301 before feature extraction and classification for use as a control signal for the robotic hand.

302 Feature extraction involves recognising useful information (e.g., spectral power, time epochs,
303 spatial filtering) for better discriminability among mental states. For example, the common
304 spatial patterns (CSP) algorithm is a type of spatial filter that learns and maximises the
305 variance of band pass-filtered EEG from one class to discriminate it to the other [93].

306

307 In the EEG-based BCI studies examined, it was found that the feature extraction and
308 classification techniques were variable between systems. Table 3 provides a summary of pre-
309 processing, feature extraction and classification techniques across the studies. There was a
310 wide variation in the implemented signal processing strategies, but a unifying theme across
311 studies was the attempt to: (i) discriminate mental states recorded in EEG across different
312 manual tasks; (ii) classify the different states to produce a viable signal.

313

314 **Table 3. BCI Feature Extraction and Classification**

Study	Pre-Processing	Feature Extraction	Classification	Hand Task
Ang et al. [60]	Band-pass (0.05-40 Hz)	Filter Bank Common Spatial Pattern	Calibration model (unspecified)	MI vs rest

		(FBCSP) algorithm [94]		
Barsotti et al. [61]	Band-pass (8-24 Hz)	ERD (β and μ -decrease), CSP	SVM with linear kernel	MI vs rest
Bauer et al. [82]	Band-pass (6-16 Hz using zero-phase lag FIR)	ERD (β -decrease)	Linear autoregressive model based on Burg Algorithm	MI vs rest
Bundy et al. [62]	Unspecified	ERD (β and μ -decrease)	Linear autoregressive model	MI (affected, unaffected) vs rest
Chowdhury et al. [63]	Band-pass (0.1 Hz-100 Hz), Notch (50 Hz)	CSP Covariance-based, ERD/ERS (β and μ -change)	SVM with linear kernel, Covariate Shift Detection (CSD)-based Adaptive Classifier	left vs right MI
Coffey et al. [77]	Band-pass (0.5 Hz-30 Hz), Notch (50 Hz)	CSP Covariance-based	Linear Discriminant Analysis (LDA) classifier	MI vs rest
Diab et al. [88]	Unspecified	Time epochs (unspecified)	Artificial Neural Network (ANN)-based Feed Forward Back Propagation	Non-MI open vs closed
Frolov al. [65]	Band-pass (5-30 Hz), FIR (order 101), IIR notch Chebyshev type I filter (50 Hz)	Time epochs (10 s)	Bayesian-based EEG covariance classifier [95]	MI (affected, unaffected) vs rest
Ono et al. [66]	Band-pass (0.5-30 Hz), notch (50 or 60 Hz)	Time epochs (700 ms), ERD (μ -decrease)	Linear Discriminant Analysis (LDA) classifier	MI vs rest
Ramos-Murguialday et al. [80]	Unspecified	Time epochs (5 s), Spatial filter, ERD/ERS (β and μ -change)	Linear autoregressive model	MI vs rest
Vukelic and Gharabaghi [84]	High-pass (unspecified)	ERD (β -decrease)	Linear autoregressive model based on Burg Algorithm	MI vs rest
Witkowski et al. [86]	Band-pass (0.4-70 Hz), Laplacian filter	ERD/ERS (β and μ -change)	Linear autoregressive model based on Yule-Walker algorithm	MI vs rest

317

318 *Robot-Assisted Rehabilitation*

319 Robotic hand rehabilitation systems provide kinaesthetic feedback to the user during BCI trials.
320 Most of these devices are powered by either DC motors, servomotors or pneumatic actuators
321 that transmit energy via rigid links or Bowden cables in a tendon-like fashion. The studies in
322 this review included single-finger [69–71], multi-finger [67] (including EMOHEX [63,64,72]),
323 full hand gloves [73,74] (including mano: Hand Exoskeleton [75] and Gloreha [76]) and full
324 arm exoskeletons with isolated finger actuation (BRAVO-Hand [61]). Nine of the studies
325 [62,72,73,75,77–81] presented their novel design of a hand rehabilitation device within the
326 article while some reported on devices reported elsewhere (i.e., in a previous study of the group
327 or a research collaborator). Two commercially-available devices were also used: AMADEO
328 (Tyromotion, Austria) is an end-effector device used in 3 studies [82–84], and Gloreha
329 (Idrogenet, Italy) is a full robotic hand glove used by Tacchino et al. [76]. AMADEO and
330 Gloreha are both rehabilitation devices that have passed regulatory standards in their respective
331 regions. AMADEO remains the gold standard for hand rehabilitation devices as it has passed
332 safety and risk assessments and provided favourable rehabilitation outcomes. The International
333 Classification of Functioning, Disability and Health (ICF) provides three specific domains that
334 can be used to assess an intervention of this kind: improving impairments, supporting
335 performance of activities and promoting participation [96,97]. In this case, a gold standard
336 device not only prioritises user safety (established early in the development process) but also
337 delivers favourable outcomes in scales against these domains. Figure 3 shows the main types
338 of robotic hand rehabilitation devices.

339

340

341 **Figure 3. Robotic hand rehabilitation devices: a) An end-effector device (Haptic Knob)**
342 **used in one of the extracted studies [60,98], b) a wearable hand exoskeleton/orthosis**
343

344 *Quality Assessment*

345 A Technology Readiness Assessment (TRA) was performed for each study and the
346 Technology Readiness Levels (TRL) are presented in Table 4. While some of the system
347 components (especially among robotic devices) were commercially available (having TRL
348 9+), we performed a TRA on the whole system (the interaction between BCI and robotics) to
349 provide an evaluation of its maturity and state-of-the-art development with regard to
350 rehabilitation medicine. We further assessed the TRL of each system at the time of the
351 publication and its subsequent development.

352

353 **Table 4. Technology Readiness Assessment of the BCI-Hand Robot Systems**

Levels	Description	Studies
TRL 1	<ul style="list-style-type: none">• Lowest level of technological readiness• Literature reviews and initial market surveys• Scientific application to defined problems

357 **Clinical Evaluation**

358 *Studies with Stroke Patients (Clinical Group)*

359 A total of 208 stroke patients (with sample size varying 3-74) were involved in the 11 clinical
360 studies. One study [60] reported a 3-armed RCT with control groups as device-only and SAT
361 while another study [65] was a multi-centre RCT with sham as the control group. Five studies
362 were uncontrolled – where the aims were either to study classification accuracies during
363 sessions [61], to monitor clinical outcomes improvement from Day 0 until the end of the
364 programme [62,70] or both [64,67]. Two studies [68,69] compared effects of the intervention
365 against SHAM feedback. Another study [63] compared the classification accuracies of
366 healthy and hemiplegic stroke patients against two BCI classifiers while the remaining study
367 [66] compared classification accuracies from stroke patients who receive congruent or
368 incongruent visual and kinaesthetic feedback.

369

370 Most of the studies adopted FMMA, ARAT and GS measurements to assess clinical
371 outcomes. Six studies [60,62,64,65,68,70] reported patient improvement in these measures
372 when subjected to BCI-hand robot interventions; in contrast with their respective controls or
373 as recorded through time in the programme. For Ang et al. [60], FMMA Distal scores were
374 reported in weeks 3, 6, 12 and 24 and the BCI-device group (N=6) yielded the highest
375 improvement in scores across all time points as compared to the device only (N=8) and SAT
376 (N=7) groups. Bundy et al. [62] reported an average of 6.20 ± 3.81 improvement in the ARAT
377 scores of its participants (N=10) in the span of 12 weeks while Chowdhury et al. [64]
378 reported a group mean difference of +6.38 kg ($p=0.06$) and +5.66 ($p<0.05$) in GS and ARAT
379 scores, respectively (N=4). Frolov et al.'s [65] multi-centre RCT reported a higher
380 improvement in the FMMA Distal, ARAT Grasp and ARAT Pinch scores of the BCI-device
381 group (N=55) when compared to the control/SHAM group (N=19), but not in the ARAT Grip

382 scores where the values are both equal to 1.0 with $p < 0.01$ for the BCI-device group and
383 $p = 0.045$ for the control.

384

385 *Studies with Healthy Participants (Prototype Group)*

386 The studies which involved pilot testing on healthy human participants had a combined total
387 of individuals (sample size ranging from 1-32) who had no history of stroke or other
388 neurological diseases. Right-handed individuals made up 44.24% of the combined population
389 while the other 55.76% were unreported. These studies aimed to report the successful
390 implementation of a BCI-robot system for hand rehabilitation and were more heterogeneous
391 in terms of study and task designs than those studies that involved clinical testing. The most
392 common approach was to design and implement a hand orthosis controlled by MI which
393 accounted for 9 out of the 19 studies and were measured based on classification accuracy
394 during the calibration/training period and online testing. Li et al. [73] and Stan et al. [79] also
395 aimed to trigger a hand orthosis but instead of MI, the triggers used by Li et al. is based on an
396 attention threshold while Stan et al. used a vision-based P300 speller BCI. Bauer et al. [82]
397 compared MI against ME using a BCI-device while Ono et al. [85] studied the
398 implementation of an action observation strategy with a combined visual and kinaesthetic
399 feedback or auditory feedback. Five more studies [76,80,81,83,84] focused on varying the
400 feedback while two more [74,86] assessed the performance and safety of a hybrid BCI with
401 EMG, EOG or both.

402

403 For the studies that had a clinical testing component, a methodological quality assessment by
404 the PEDro Scale was performed. Two studies which appeared on the PEDro search [60,65]
405 had predetermined scores in the scale and were extracted for this part while the rest were
406 manually evaluated by the authors. Table 5 shows the results of the methodological quality

407 assessment against the scale. Note that in the PEDro Scale, the presence of an eligibility
408 criteria is not included in the final score.

409

413 **Discussion**

414 To the best of our knowledge, this article was the first to compile BCI-driven robotic systems
415 specific for hand rehabilitation. During this review, we found several limitations present
416 among the studies collected and we examine these in more detail here and provide
417 recommendations for future work in this area.

418
419 To provide clarity on the state-of-the-art and development of BCI-hand robot systems, we
420 looked into the maturity of technology used in each study and determined by its readiness
421 level (TRL). All but one in the prototype group was rated as having TRL 3 while the clinical
422 group was more varied in their TRL (ranging from 5-7). The system used by Witkowski et al.
423 [86], a prototype study, was rated TRL 4 due to the study being performed on the basis of
424 improving and assessing its safety features. It is also worth noting that while a formal safety
425 assessment was not performed for the TRL 3 prototypes of Stan et al. [79], Randazzo et al.
426 [75] and Tacchino et al. [76], safety considerations and/or implementations were made; a
427 criterion to be satisfied before proceeding to TRL 4. The system used by Chowdhury et al. is
428 a good example of improving a TRL from 5 to 6 with a pilot clinical study published within
429 the same year [63,64]. The two systems used in the RCT studies by Ang et al. [60] and
430 Frolov et al. [65] achieved the highest score (TRL 7) among all of the studies which also
431 meant that no BCI-hand robot system for stroke rehabilitation has ever been registered and
432 commercially-released to date. This suggests that such systems lack the strong evidence that
433 would propel commercialisation and technology adoption.

434
435 Heterogeneity in the study designs was apparent in both the clinical and prototype groups.
436 The lack of control groups and random allocation in clinical studies (e.g., only 2 out of 7
437 studies are in the huge sample size RCT stage) made us unable to perform a meta-analysis of

438 effects and continue the study by Cervera et al [36] with a focus on BCI-hand robot
439 interventions. Results from the methodological quality assessment showed that only two
440 studies [68,69] had a score of 7 in the PEDro scale. Although non-conclusive, these results
441 support the notion that most of the studies are not aligned with the criteria of high-quality
442 evidence-based interventions. These factors also raise the need to develop clearly defined
443 protocols when conducting BCI-hand robot studies on stroke patients. Until new systems
444 have been assessed on this standard, it will be difficult to generate strong evidence supporting
445 the effectiveness of BCI-robotic devices for hand rehabilitation.

446

447 In the development of any BCI-robotic device there are several design and feature
448 considerations that need to be made to ensure that the systems are both fit for purpose and
449 acceptable to the end-user. These design considerations must go beyond the scope of
450 understanding the anatomy of the hand and the physiology of motor recovery in response to
451 therapy. Feedback from stroke patients should be an essential part of this design process. the
452 extracted studies, we surveyed the extent of end-user involvement in the initial stages of
453 development (i.e., through consultations, interviews and therapy observations) and we found
454 that there were no explicit statements about these in the reports. We recommend, as good
455 practice, for future work in this area to report the type and degree of patient and/or physician
456 involvement in device development to allow reviewers and readers to more readily gauge the
457 potential usability of the system.

458

459 We were able to profile the BCI-hand robot systems regarding their technical specifications
460 and design features. In hardware terms, a BCI-hand robot system involves three major
461 components: (1) An EEG data acquisition system with several electrodes connected to a
462 signal amplifier; (2) A computer where raw EEG data is received then processed by filters

463 and classifiers and where most of the cues and feedback during training is presented via a
464 visual display; (3) a robotic hand rehabilitation system for providing the physical therapy
465 back to the user.

466

467 The majority of the studies (N=19) used a BCI solely based on EEG while the rest were
468 combined with other sensors: EEG with EMG [60,63,72,76,80–83], EEG with force sensors
469 [64] and an EEG-EMG-EOG hybrid system [74,86]. The purpose of this integration is mainly
470 to improve signal quality by accounting for artefacts or to provide added modalities. Action
471 potentials such as those caused by ocular and facial movements interfere with nearby
472 electrodes and the presence of an added electrophysiological sensor accounting for these
473 would enable the technician to perform noise cancellation techniques as a first step in signal
474 processing. Almost all of the studies included used a standard EEG system with “wet”
475 electrodes (e.g., g.USBamp by g.tec and BrainAmp by Brain Products) while three used
476 Emotiv EPOC+, a semi-dry EEG system that uses sponge conductors infused with saline
477 solution. While the use of dry electrodes has been observed in pilot and prototype studies of
478 BCI-hand robot systems [52,49,78,87] and other motor imagery experiments [99–102], no
479 dry EEG system was used in the final 30 studies that tested healthy or stroke participants. It is
480 expected that as dry EEG systems continue to improve, their use in clinical studies of BCI
481 will also become increasingly prominent.

482

483 The degree of BCI-robotic control for the majority of the studies (N=26) was limited to
484 triggering the device to perform grasping (opening and closing of hand) and pinching (a
485 thumb-index finger pinch or a 3-point thumb-index-middle finger pinch) movements using
486 MI and other techniques. This means that no robotic control setup among the screened studies
487 were able to perform digit-specific MI. This is a limitation caused by the non-invasive setup

488 of EEG and is due to the low spatial resolution brought by the distances between electrodes
489 [103]. The homunculus model, a representation of the human body in the motor strip, maps
490 the areas of the brain where activations have been reported to occur for motor processes. The
491 challenge of decoding each finger digit MI in one hand is that they only tend to occupy a
492 small area in this strip. Hence even the highest resolution electrode placement system (i.e.,
493 the five percent or 10-5 system – up to 345 electrodes) would have difficulties accounting for
494 digit-specific MI for BCI. In contrast to EEG, electrocorticography (ECoG) have been used
495 to detect digit-specific MI. The electrodes of ECoG come in contact directly with the motor
496 cortex and is an invasive procedure; making it non-ideal for use in BCI therapy [104]. It is
497 worth noting however that some studies were successful in implementing continuous control
498 based on ERD/ERS patterns: Bundy et al. [62] and Norman et al. [67] were able to apply
499 continuous control of a 3-DOF pinch-grip exoskeleton based on spectral power while Bauer
500 et al. [82] provided ERD-dependent control of finger extension for an end-effector robot.
501 These continuous control strategies have been shown to be very useful in BCI-hand robots for
502 assistive applications (i.e., partial or full device dependence for performing ADL tasks [105]).
503 Whether this type of control can significantly improve stroke recovery is still in question as
504 the strategy of robots for stroke rehabilitation can be more classified as a therapeutic
505 “exercise” device.

506

507 Signal processing and machine learning play a vital role in the development of any EEG-
508 based BCI. The pre-processing techniques (e.g., filtering, artefact removal), types of features
509 computed from EEG, and the classifier used in machine learning can significantly affect the
510 performance of the robotic system in classifying the user’s intent via MI [106]. This
511 systematic review has revealed that approaches to develop MI EEG-based BCI are highly
512 diverse in nature, which makes it difficult to compare across the systems and hinders the

513 development of new BCI systems informed by the strengths and weaknesses of existing state-
514 of-the-art systems. The diversity in the design process can be beneficial to develop complex
515 MI EEG-based BCI systems to achieve high efficiency and efficacy. However, such newly
516 developed systems should be open sourced and easily reproducible by the research
517 community to provide valid performance comparisons and drive forward the domain of
518 robotic-assisted rehabilitation.

519

520 In addition to MI, other strategies for robotic control were reported. Diab et al. [88] and King
521 et al. [89] both facilitated the movements of their respective orthoses by physical practice
522 while Stan et al. [79] utilised a P-300 evoked potential speller BCI, where the user visually
523 focused on a single alphanumeric character situated in a grid. The chosen character then
524 corresponded to a command for the hand orthosis thereby producing the desired stimulus for
525 the patient. While the latter study reported 100% accuracy rate in terms of intention and
526 execution, the EEG channels were situated in the visual cortex rather than the motor strip
527 which deviates from the goal of stimulating the desired brain region for plasticity.

528

529 In order to facilitate hand MI and account for significant time-points in the EEG data, all the
530 studies employed a cue-feedback strategy during their trials. 19 of the studies presented a
531 form of visual cue while the rest, except for two unspecified [69,87], involved cues in
532 auditory (“bleep”) [76,80–83], textual [78,79,89] or verbal [88] forms. As for the provision of
533 a matching sensory feedback, 16 studies presented a combination of kinaesthetic and visual
534 feedback with some also providing auditory feedback during successful movement attempts.
535 All the studies provided kinaesthetic feedback through their robotic devices. Some systems
536 with visual feedback, such as Wang et al. [68], Li et al. [73], Chowdhury et al. in both of their
537 clinical studies [63,64] and Ono et al. in their clinical [66] and pilot testing experiments [85],

538 used a video of an actual hand performing the desired action. Ang et al. [60] and Stan et al.
539 [79], in a different strategy, provided visual feedback through photo manipulation and textual
540 display, respectively. While the latter two studies reported promising results (with Ang et al.
541 in RCT stage and Stan et al. having 100% classification accuracy), it should also be
542 considered that such cue and feedback types (including Graz visualisations and auditory
543 forms) are non-representative of hand movement and may not provide the same stimulation
544 as a geometrical representation of a hand moving its desired course. This may be essential
545 when we base principles of stroke recovery in alignment with how MI correlates with AO –
546 an underlying theme of the motor simulation theory proposed by Jeannerod [15]. Figure 4
547 shows how different kinds of visual cue and feedback can be presented to participants to help
548 facilitate MI.
549

550

551 **Figure 4. Visual cue and feedback during MI trials in different conditions. (a) Graz MI**
552 **visualisations, (b) video recordings of hand movement and (c) virtual hand**
553 **representation through VR/AR**

554 **Future Directions**

555 There is clearly great potential for the use of BCI-hand robots in the rehabilitation of an
556 affected hand following stroke. Nevertheless, it is important to emphasise that there is
557 currently no solid evidence to support the use of such systems within clinical settings.
558 Moreover, the purported benefits of these systems rest on conjectures that require empirical
559 evidence. In other words, there are grounds for supposing that MI could be useful within
560 these rehabilitation settings but no supporting evidence. This systematic review has also
561 revealed that there are a number of technological limitations to existing BCI-hand robotic
562 systems. We stress an urgent need to address these limitations to ensure that the systems meet
563 the minimum required levels of product specification (in measuring brain activity, processing
564 signals, delivering forces to the hand and providing rich feedback and motivating settings).
565 We question the ethics or usefulness of conducting clinical trials with such systems until they
566 can demonstrate minimum levels of technological capability. We consider below what
567 standards these systems should obtain before subjecting them to a clinical trial and discuss
568 might constitute an acceptable standard for a clinical trial.

569

570 **Ideal Setup for a BCI-hand Robot**

571 We summarise the information revealed via the systematic review about what constitutes an
572 acceptable setup for a BCI-hand robot for stroke rehabilitation. We focus on improving
573 individual components in data acquisition, data processing, the hand rehabilitation robot, and
574 the visual cue and feedback environment. Table 6 presents the features and specifications of a
575 fully integrated acceptable system.

576 **Table 6. Exemplary Features and Specifications of Future BCI-Hand Robot Systems**

577

Component	Features and Specifications
Data Acquisition System and Software	<ul style="list-style-type: none"> • Dry EEG system with 8-16 channels, comfortable and easy to use • Inclusion of other bio-signal sensors such as EMG, EOG, force, accelerometers to remove artefacts and improve classification • Robust and reliable signal processing software: machine learning-based algorithms that discriminate brain states such as MI or evoked potentials and have lower calibration times
Hand Robot	<ul style="list-style-type: none"> • Safe, comfortable and aligned with the hand’s range of motion • Effective in providing kinaesthetic feedback • Use of back-drivable or soft actuators that effectively assist movement without additional injury • Multiple levels of safety and emergency features (mechanical, electronic, software), clear and obvious operation
Visual Cue and Feedback	<ul style="list-style-type: none"> • Provide rich visual cue and feedback to intended tasks, geometric representation of the hand (video or simulated environment), can be in multiple platforms such as display monitors or VR/AR headsets • Gamification of therapy exercises to provide an engaging regime to stroke patients

578

579

580 The implementation of these features in an ideal BCI-robot setup needs to be weighed against
581 socioeconomic factors in healthcare delivery for it to be considered market ready. An ideal
582 BCI system should provide above chance-level classification (>60%) after the first session on
583 the first day of therapy. Ideally, the classification algorithm should also translate to following
584 sessions or days; reducing the number of training sessions and focusing on the main therapy
585 tasks. An alternative approach is to focus on making the setup an engaging experience. In
586 other words, the delivery of intervention can be started immediately the patient wears the
587 EEG cap and runs the BCI system. For the hand robot system, more straightforward criteria

588 can be followed with the existence of the numerous design protocols, regulation standards
589 and assessment matrices mentioned in this review. Nevertheless, end-user involvement in the
590 design with the prioritisation of safety while allowing the most natural hand movement and
591 ROM as possible is the recommended goal.

592

593 **Ideal Setup for Clinical Trials**

594 We also propose a set of specialised criteria for BCI-hand robot systems in addition to the
595 standard motor improvement scores (e.g. ARAT, FMMA) evaluated during clinical trials.
596 Firstly, classification accuracies between intended and interpreted actions from the data
597 acquisition and software component should always be accounted to track the effectiveness of
598 BCI in executing the clinical task. In addition to this, system calibration and training
599 procedures, especially its duration, should be detailed in the protocol to document the
600 reliability of the classification algorithm. There is not much to consider in the use of robotic
601 devices as they are most likely to be mature (if not yet commercially available) before being
602 used as the hardware component in the study. However, the devices' functionality (i.e., task
603 to be performed, degree of control and motion, actuation and power transmission etc.) should
604 always be stated as they contribute to the evaluation of interactions between other
605 components in the system. Lastly, controls for the clinical study must always be included,
606 even with small-scale patient studies. As discussed in this article, these controls may be in the
607 form of sham, standard arm therapy (SAT), standard robotic therapy, congruency feedback
608 and quality of stimuli among others. Having regarded and implemented these criteria would
609 help homogenise the clinical data for future meta-analyses, strengthen evidence-based results
610 and provide a reliable way of documentation for individual and/or interacting components.

611 **Proposed roadmap**

612 We suggest that the immediate focus for BCI-controlled robotic device research should be
613 around the engineering challenges. It is only when these challenges have been met that it is
614 useful and ethical to subject the systems to clinical trials. We recommend that the challenges
615 be broken down into the following elements: (1) data acquisition; (2) signal processing and
616 classification; (3) robotic device; (4) priming and feedback environment; (5) integration of
617 these four elements. The nature of these challenges means that a multidisciplinary approach is
618 required (e.g. the inclusion of psychologists, cognitive neuroscientists and physiologists to
619 drive the adoption of reliable neural data acquisition). It seems probable that progress will be
620 made by different laboratories tackling some or all of these elements and coordinating
621 information sharing and technology improvements. Once the challenges have been met (i.e.
622 there is a system that is able to take neural signals and use these to help drive a robotic
623 system capable of providing appropriate forces to the hand within a motivating environment)
624 then robust clinical trials can be conducted to ensure that the promise of this approach does
625 translate into solid empirical evidence supporting the use of these systems within clinical
626 settings.

627 **Conclusions**

628 Research on BCI-controlled robotic devices for hand rehabilitation after stroke is a rapidly
629 growing field and is gaining traction in the academic and medical research communities. The
630 three main objectives of this systematic review were: (1) to survey how BCI technologies are
631 utilised in controlling robotic devices for hand rehabilitation, (2) to determine the state-of-
632 the-art developments in BCI systems in terms of hand MI resolution and degree of robotic
633 control, and (3) to assess the clinical significance of BCI-hand robot systems by accounting
634 clinical studies with outcome measures relating to motor recovery. Here, we were able to
635 address these three and provide insight on the future of BCI-controlled robotics for stroke
636 therapy.

637

638 We surveyed 30 EEG-based BCI-hand robot systems designed for stroke with majority of the
639 studies (N=19) in their prototype development and pilot testing stages having TRL scores of
640 3-4. The rest of the studies (N=11) involved a clinical component into it, having tested on
641 stroke patients. The systems used in the clinical group were rated with the highest
642 technological readiness: TRL 7 for two studies undergoing RCT. Profiling the EEG
643 acquisition systems confirmed the still dominance of standard EEG systems that uses “wet”
644 electrodes over the recent dry electrode systems. However, as the latter’s technology
645 continues to improve in the next years, we may see a positive shift towards these techniques
646 in terms of usage and preference. The common goal among these studies is to successfully
647 discriminate and with high accuracy a user’s intent via motor imagery. While most have
648 reported reliable, above chance-level accuracy rates, we observe the limitations evident in
649 hand motor imagery resolution (e.g., intention to grasp or pinch as opposed to rest,
650 discriminating from left and right movement, signal processing techniques) and the degree of
651 robotic control (i.e., triggering and continuous control). The task designs, cues and matching

652 sensory feedback modes play an important role in motor imagery ability. We give attention to
653 the inferior visual stimuli presented in most of the trials and suggest the use of a rich and
654 engaging one through the different immersive platforms such as Virtual Reality and
655 Augmented Reality. We also report that the clinical adoption of BCI-hand robots is still in its
656 infancy due to few studies reporting significant improvements in the functional recovery of
657 stroke patients. We suggest the development of a standard protocol in assessing clinical
658 outcomes as an effort to strengthen the argument that these systems are not only
659 economically feasible but also viable and robust for the therapy of motor impairment post-
660 stroke.

661

662 Finally, we recommend that future developers focus on end-user involvement in the early
663 design stages, achieving the successful integration of the individual components and making
664 the system as safe and cost-effective as possible without compromising on reliability and
665 robustness. These steps should allow this promising technology to advance, be adopted by the
666 stakeholders and improve the quality of life for stroke survivors.

708 **Declarations**

709 **Funding**

710 This work was supported by a Newton Fund PhD grant, ID 331486777, under the Newton-
711 Agham partnership. The grant is funded by the UK Department for Business, Energy and
712 Industrial Strategy and the Philippine Commission on Higher Education and delivered by the
713 British Council. For further information, please visit www.newtonfund.ac.uk.

714

715 **Availability of Data and Materials**

716 A full database of selected studies including those extracted during the search and selection
717 process is available from the corresponding author on reasonable request.

718

719 **Authors' Contributions**

720 PDEB and ECS performed the initial search and screening of the studies. MA performed the
721 analysis of signal processing techniques. AA, AEJ and RJH made contribution to the
722 robotics, design and other engineering aspects of the current work. FM provided analysis
723 related to EEG and BCI. MMW contributed to the clinical and overall direction of the review.
724 PDEB, FM and MMW were the major contributors to the writing of the manuscript. All
725 authors read and approved the final manuscript.

726

727 **Competing Interests**

728 The authors declare that they have no competing interests.

729

730 **Ethics Approval and Consent to Participate**

731 Not applicable.

732

733 **Consent for Publication**

734 Not applicable.

735

736 **Acknowledgements**

737 Not applicable.

Table 2. Summary of Studies

Authors	Participants	Study Design	Task Design	BCI-Hand Robot	Main Outcomes
Studies involving stroke patients					
Ang et al., 2014 [60]	N=27 (7F:14M) Moderate to severe impairment of UE function Mean age: 54.2y Mean stroke duration: 385.1 days	3-armed RCT of motor function with MI-BCI-device as intervention Control groups: device only (Haptic Knob), SAT	Photo manipulation: hand opening and closing, pronation and supination Cue: visual (photo) Feedback: visual (photo) and kinaesthetic	EEG: 27 channels to classify ERD/ERS and coupled with EMG to confirm MI Device: Haptic Knob, 2-DOF for hand grasping and knob manipulation Actuation: DC brushed motors with linear belt drive Control: trigger	Clinical outcome measure: FMMA Distal, improvement in weeks 3, 6, 12, 24 BCI-device group = 2.5±2.4, 3.3±2.3, 3.2±2.7, 4.2±3.1 Device only group = 1.6±2.5, 2.9±3.0, 2.5±2.6, 2.5±3.0 SAT group = 0.4±1.1, 1.9±1.9, 1.0±1.3, 0.3±2.1
Barsotti et al., 2015 [61]	N=3 (1F:2M) Chronic stroke survivors with right arm hemiparesis Mean age: 62±12y	Probing MI classification by BCI training, time-frequency analysis and robot trajectories Uncontrolled	Reaching-grasping-releasing Cue: visual Feedback: kinaesthetic Minimum time required to perform MI = 2s	EEG: 13 channels to classify ERD Device: BRAVO 2-DOF hand orthosis attached to full UE exoskeleton Actuation: DC motors with rigid links Control: trigger	Mean classification accuracy during BCI training = 82.51±2.04% Average delay from visual cue to robot initiation = 3.45±1.6s Average delay due to patient's ability to start MI = 1.45s
Bundy et al., 2017 [62]	N=10 Chronic hemiparetic stroke with moderate to severe UE hemiparesis Mean age: 58.6±10.3y	Motor function evaluation before and after intervention by MI-BCI from unaffected hemisphere Uncontrolled	Opening of affected hand Cue: visual Feedback: visual and kinaesthetic	EEG: 8 channels to classify ERD Device: 3-pinch grip, 1-DOF hand exoskeleton	Clinical outcome measure: ARAT Score, improvement from baseline to completion (12 weeks) Mean ± SD = 6.20±3.81

Bundy et al. (cont'd)				Control: continuous depending on spectral power	Note: 5.7 ARAT Score is the minimal clinically important difference in chronic stroke survivors
Carino-Escobar et al. 2019 [70]	N=9 (4F:5M) Subacute ischaemic stroke Mean age: 59.9±2.8y Mean stroke duration: 158(±74)-185(±73) days	Determine longitudinal ERD/ERS patters and functional recovery with BCI-robot Uncontrolled	Extension-flexion of hand fingers Cue: visual (Graz MI) Feedback: visual and kinaesthetic	EEG: 11 channels to classify ERD/ERS Device: hand finger orthosis Actuation: DC motor with screw system for linear displacement, flexible links Control: trigger	FMA-UE: N=3 reported equal or higher than 3 score gains, N=3 no score gains, Mean longitudinal ERD/ERS: beta bands have higher association with time since stroke onset than alpha, and strong association with UL motor recovery
Chowdhury et al., 2018-b [63]	N=20 10 healthy and 10 hemiplegic stroke patients Mean age (healthy, stroke): 41±9.21y, 47.5±14.23y	Probe non-adaptive classifier (NAC) vs. Covariate Shift adaptive classifier (CSAC) of MI in EEG Control group: healthy participants	Extension-flexion of hand fingers Cue: visual Feedback: visual and kinaesthetic	EEG: 12 channels with EMG to classify ERD/ERS Device: EMOHEX 3-finger, 3-DOF each, exoskeleton (thumb, index, middle) Actuation: servomotors with rigid links Control: trigger	Mean classification accuracies during BCI training: Healthy group: calibration = 78.50±9.01%, NAC = 75.25±5.46%, CSAC = 81.50±4.89% Patient group: calibration = 79.63±13.11%, NAC = 70.25±3.43%, CSAC = 75.75±3.92%
Chowdhury et al., 2018-c [64]	N=4 (2F:2M) Hemiplegic stroke patients, right-handed, left hand impaired Mean age: 44.75±15.69y Mean stroke duration: 7 ±1.15mo	Motor function evaluation by using active physical practice followed by MI-BCI-controlled device intervention Uncontrolled	Extension-flexion of hand fingers Cue: visual Feedback: visual and kinaesthetic	EEG: 12 channels with force sensors to classify ERD/ERS Device: EMOHEX 3-finger, 3-DOF each, exoskeleton (thumb, index, middle) Actuation: servomotors with rigid links Control: trigger	Classification accuracies of 4 participants: P01 = 81.45±8.12%, P02 = 70.21±4.43%, P03 = 76.88±4.49%, P04 = 74.55±4.35% Clinical outcome measures: GS and ARAT Scores, improvement from baseline to completion (6 weeks) GS scores: group mean difference = +6.38 kg, p=0.06

Chowdhury et al., 2018-c (cont'd)					ARAT scores: group mean difference = +5.66, p<0.05
Frolov et al., 2017 [65]	N=74 (26F:48M) BCI 55: Control 19 Subacute or chronic stroke with mild to hemiplegic hand paresis, right-handed	Multi-centre RCT of MI-BCI-controlled hand exoskeleton Control group: SHAM	3 Tasks: (1) motor relaxation, (2) imagery of left-hand opening, (3) imagery of right-hand opening Cue: visual Feedback: visual and kinaesthetic	EEG: 30 channels to classify the three mental tasks by Bayesian classifier based on covariance matrices Device: hand exoskeleton by Neurobotics, Russia Actuation: pneumatic motors with spring flexors Control: trigger	Mean classification accuracy during BCI training = 40.6% Clinical outcome measures: FMMA Distal and ARAT Scores, improvement in 10 days of training FMMA Distal = 2.0, p<0.01 (BCI) and 1.0, p=0.046 (control) ARAT Grasp = 3.0, p<0.01 (BCI) and 1.0, p=0.0394 (control) ARAT Grip = 1.0, p<0.01 (BCI) and 1.0, p=0.045 (control) ARAT Pinch = 1.0, p<0.01 (BCI) and 0.0, p=0.675 (control)
Norman et al., 2018 [67]	N=8 (All male) Cortical and subcortical single haemorrhagic or ischaemic stroke (at least 6 months) Mean age: 59.5±11.8y	Implementation of sensorimotor rhythm (SMR) control on robot-assistive movement Uncontrolled	Extension of hand finger Cue: visual Feedback: visual and kinaesthetic	EEG: 16 channels mapping SMR changes Device: FINGER robot Actuation: Linear servo-tube actuator with rigid links Control: Visual - continuous (colour change respective to SMR), Robot - trigger	Mean classification accuracies: 8 participants: 83.1%, 76.3%, 73.3%, 68.2%, 74.5%, 86.5%, 47.9%, 40.0% Box and blocks test (BBT): At screening: mean score = 14.3±10.0, mean change after therapy = 4.3±4.5 (range 0-12). Higher score changes in participants who demonstrated SMR control but not significant (p=0.199)
Ono et al., 2016-a [66]	N=21 (9F:12M) Chronic stroke patients with hemiplegic hands Mean age: 57.9±2.4y	Probe congruent vs. incongruent MI feedback strategies Control groups: congruent (synchronous proprioceptive and visual feedback) and	Grasping of a tennis ball with a hand Cue: visual (video of hand performing action) Feedback: visual and kinaesthetic	EEG: 9 channels to classify ERD Device: Power Assist Hand - Team ATOM, Atsugi, Japan	Mean classification accuracies: Congruent feedback = 56.8±5.2%, chance level=36.4±4.5% Incongruent feedback = 40.0±3.5%, chance level 35.4±4.5%

Ono et al., 2016-a (cont'd)		incongruent (proprioceptive feedback given 1s after visual)		Actuation: pneumatic motors with rigid links Control: trigger	
Tsuchimoto et al., 2019 [69]	N=18 (3F:14M) Chronic haemorrhagic or ischaemic stroke (from 2mo onwards) Mean age: 58±10y	Implementation of MI-controlled robotic orthosis as neurofeedback Control: SHAM	Extension of hand finger Cue: unspecified Feedback: kinaesthetic and electrical stimulation	EEG: 5 channels to classify MI Device: robotic finger orthosis Actuation: servo motors with rigid links Control: trigger	Significant time-intervention interaction in the ipsilesional sensorimotor cortex. Higher coactivation of sensory and motor cortices for neurofeedback group in the ipsilesional sensorimotor cortices as compared to SHAM
Wang et al., 2018 [68]	N=24 (4F:20M) Chronic stroke patients with paralysed hands Mean age: 54±9y	Implementation of action observation and motor imagery (AO+MI) with kinaesthetic feedback Control: SHAM	Hand grasping Cue: visual (video of hand action / textual cues in SHAM group) Feedback: visual and kinaesthetic	EEG: 16 channels to classify ERD Device: robot hand Control: Trigger	AO+MI with kinaesthetic feedback group showed significant improvements in FMA-UE across longitudinal evaluation [$\chi^2(2) = 7.659, p = 0.022$], no significant difference in SHAM group [$\chi^2(2) = 4.537, p = 0.103$]

Authors	Participants	Study Design	Task Design	BCI-Hand Robot	Main Outcomes
Studies involving healthy participants					
Bauer et al., 2015 [71]	N=20 (11F:9M) Right-handed Mean age: 28.5±10.5y	Study on MI as compared to motor execution (ME) using BCI-device	Opening of left hand Cue: auditory Feedback: kinaesthetic	EEG: 31 channels to detect ERD, with EMG to classify MI from execution and account for tonic contraction Device: Amadeo, Tyromotion, Austria Control: discontinuation of ERD stops finger extension	Principal component analyses (between MI and execution) generated coefficients for the visual (VIS) and kinaesthetic (KIS) imagery scale, BCI-robot performance (BRI), tonic contraction task (MOC) and visuomotor integration task (VMI). VIS and KIS yielded high coefficients on MI while MOC and VMI yield high coefficients on ME. BRI show high coefficient yields on both MI and ME.

Cantillo-Negrete et al., 2015 [72]	N=1	Design and implementation of a MI-controlled hand orthosis	Extension-flexion of right-hand finger Cue: visual (modified Graz) Feedback: kinaesthetic	EEG: 11 channels to detect MI Device: 1-DOF hand finger orthosis Actuation: DC motor with screw system for linear displacement, flexible links Control: trigger	Correctly classified trials = 78%
Chowdhury et al., 2015-a [73]	N=6 Age range: 20-30y	Study of cortico-muscular coupling in robotic finger exoskeleton control	Extension-flexion of hand fingers Cue: visual Feedback: kinaesthetic	EEG: 10 channels with EMG to classify MI Device: 3-finger, 3-DOF each, exoskeleton (thumb, index, middle) Actuation: servomotors with rigid links Control: trigger	Mean classification accuracies: passive execution = 69.17%, hand execution = 71.25%, MI = 67.92%
Coffey et al., 2014 [74]	N=3 (All male) Right-handed Age range: 24-28y	Design and implementation of a MI-controlled hand orthosis	Hand digit and wrist contraction and extension Cue: visual (Graz MI) Feedback: kinaesthetic	EEG: 27 channels to classify MI Device: hand glove controlled by Arduino Actuation: pneumatic Control: trigger	Glove inflation-deflation cycle = 22s Classification accuracies of 3 participants: A = 92.5%, B = 90.0%, C = 80.0%
Diab et al., 2016 [75]	N=5	Design and implementation of EEG-triggered wrist orthosis with accuracy improvement	Hand opening and closing Cue: verbal instruction Feedback: kinaesthetic	EEG: 14 channels to detect hand movement-related EEG Device: actuated Talon wrist orthosis Actuation: linear Control: trigger	Mean classification accuracies: simulation studies = 95%, online BCI training = 86%

Fok et al., 2011 [76]	N=4	Design and implementation of a MI-controlled hand orthosis	Hand opening and closing Cue: unspecified Feedback: visual (cursor movement) and kinaesthetic	EEG: 14 channels to detect MI-related ERD Device: actuated Talon wrist orthosis Actuation: linear actuator Control: trigger	EEG signals from imagined hand movement was correlated with the contralesional hemisphere and utilised to trigger the actuation of orthosis ERD was detected from 12 Hz bin power of EEG during move condition
Li et al., 2019 [77]	N=14 (4F:10M) Mean age: 23.8±0.89y	Design and implementation of an attention-controlled hand exoskeleton with rigid-soft mechanism	Hand grasping Cue: visual (video of hand action) Feedback: kinaesthetic	EEG: 3 channels to map signals relative to attention Device: hand exoskeleton Actuation: linear actuator with rigid-soft mechanism Control: Trigger	Mean classification accuracy: 95.54% actuation success rate against the attention threshold
Holmes et al., 2012 [78]	N=6 (All male, young adults)	Design and implementation of a MI-controlled hand orthosis	Hand opening and closing Cue: textual Feedback: kinaesthetic	EEG: 14 channels to detect hand movement-related EEG Device: ExoFlex Hand Exoskeleton controlled by Arduino Actuation: linear actuator connected to chained links that flex Control: trigger	Classification accuracies of 6 participants: T001 = 95%, T002 = 98%, D001 = 91%, U001 = 93%, E001 = 87%, E002 = 86%
King et al., 2011 [79]	N=1 (Female) 24y	Contralateral control of hand orthosis using EEG-based BCI	Right hand idling and grasping Cue: textual Feedback: visual and kinaesthetic	EEG: 63 channels to control contralateral hand movement Device: hand orthosis	Offline classification accuracy = 95.3±0.6%, $p < 3.0866 \times 10^{-25}$ Average lag from voluntary contractions to BCI-robot control = 2.24 ± 0.19s (after 5 sessions)

King et al. (cont'd)				Actuation: servomotors attached to Bowden cables as tendons	
Naros et al., 2016 [80]	N=32 (16F:16M) Mean age: 25.9±0.5y	2x2 factorial design with parameters: adaptive classifier threshold and non-adaptive classifier threshold, contingent feedback and non-contingent feedback	Opening of right hand Cue: auditory Feedback: kinaesthetic	EEG: 32 channels to detect ERD, with EMG to classify MI (FC3, C3, CP3 used) Device: Amadeo, Tyromotion, Austria Control: trigger	Significant enhancement in group 1 (adaptive classifier + contingent feedback), p=0.0078 Significant reduction in group 4 (non-adaptive classifier + non-contingent feedback), p=0.0391 Motor performance improvement over baseline from first and last tasks, significant results: Group 1 (adaptive classifier + contingent feedback), p=0.0313 Group 4 = (non-adaptive classifier + non-contingent feedback), p=0.0411
Ono et al., 2018-b [81]	N=28 Right-handed except 1	Implementation of an action observation strategy with visual and proprioceptive, or auditory feedback to MI Control group: SHAM	Grasping of a tennis ball with a hand Cue: visual (video of hand performing action) Feedback: visual, kinaesthetic and auditory	EEG: 9 channels to classify ERD Device: Power Assist Hand - Team ATOM, Atsugi, Japan Actuation: pneumatic motors with rigid links Control: trigger	AO+MI + proprioceptive and visual feedback: Mean MI-ERD powers of correct feedback vs SHAM provide significant interaction, $F_{1,17}=6.618$, p=0.020 (6 days) Statistically significant increase in MI-ERD power in correct feedback group over baseline, p=0.012 (6 days)
Stan et al., 2015 [82]	N=9	Trigger a hand orthosis using a P300 speller BCI	Spell E (enable), A (hand opening) and B (hand closing) in P300 speller BCI to perform hand grasping, moving and releasing objects Cue: textual (spelling)	EEG: 8 channels focusing on visual cortex Device: hand orthosis Actuation: 2 servomotors and	Mean classification accuracies: 100% (on 6 th letter flash during calibration)

Stan et al. (cont'd)			Feedback: visual (textual) and kinaesthetic	current feedback circuitry Control: trigger	
Ramos-Murguialday et al., 2012 [83]	N=23 Mean age (contingent positive, contingent negative, SHAM): 26.6±4y, 26.5±5y, 26.2±2y	Probing MI with proprioceptive feedback Experimental groups: contingent positive, contingent negative feedback Control group: SHAM	5 tasks: MI without direct control, MI with direct control, passive, active, rest Cue: auditory Feedback: visual and kinaesthetic	EEG: 61 channels with EMG to classify ERD/ERS Device: hand orthosis Actuation: DC motor M-28 with a worm gearhead and Bowden cables for each finger Control: trigger	Contingent positive feedback provided higher BCI performance during MI without feedback than contingent negative and SHAM; and higher during MI with or without feedback as compared to rest
Ramos-Murguialday and Birbaumer, 2015 [84]	N=9 Right-handed Mean age: 26.6±4y	Detect oscillatory signatures of motor tasks during EEG	5 tasks: MI without direct control, MI with direct control, passive, active, rest Cue: auditory Feedback: visual and kinaesthetic	EEG: 61 channels with EMG to classify ERD/ERS Device: hand orthosis Actuation: DC motor M-28 with a worm gearhead and Bowden cables for each finger Control: trigger	Significant change in power in all frequency ranges during MI with direct control before trial initiation Kinaesthetic feedback increased significant changes in alpha and beta power; therefore, increasing BCI performance
Randazzo et al., 2018 [85]	N=9 (2F:7M) Mean age: 23±5y	Design and implementation of a hand orthosis with testing of kinaesthetic effects in EEG	4 tasks: rest (REST), exoskeleton-induced hand motions (EXO), MI of right hand (MI), exoskeleton-induced hand motions plus MI (MIEXO) Cue: visual Feedback: kinaesthetic	EEG: 16 channels to detect MI Device: mano hand exoskeleton Actuation: linear servomotors attached to Bowden cables as tendons Control: passive (exoskeleton not dependent on MI to	Mean classification accuracies among groups: (vs REST) MI = 63.02±5.91%, EXO = 69.64±5.74%, MIEXO = 72.19±6.57% MIEXO vs EXO = 69.91±9.86% Chance level at 95% confidence = 58% (N=50 trials)

Randazzo et al. (cont'd)				move during MIEXO task)	
Tacchino et al., 2017 [86]	N=8 (7F:1M) Right-handed Mean age: 26.3±1.9y	2x2 factorial design with parameters: glove, no glove, active movement, passive movement	Opening and closing of hand, 4 tasks: (A) glove with active movement, (B) glove with passive movement, (C) no glove with active movement, (D) no glove and no movement Cue: auditory Feedback: kinaesthetic	EEG: 19 channels with EMG to detect ERD/ERS (C3, F3, Cz used) Device: Gloreha hand rehabilitation glove Actuation: electric actuators with Bowden cables on each finger Control: passive (glove not dependent on brain-state during tasks)	Statistically significant ERD changes in beta and mu bands were observed to initiate earlier in tasks A and C (involves active movement) Stronger and longer ERD was observed in tasks A and B (involves robotic assistance) suggesting reinforced afferent kinaesthetic feedback
Vukelic and Gharabaghi, 2015 [87]	N=11 (4F:7M) Right-handed Mean age: 25.83±3.1y	Assessment sensorimotor activity during MI with either visual or kinaesthetic feedback	Right hand opening Cue: visual (coloured cursor ball) Feedback: visual and kinaesthetic (separated by experimental groups)	EEG: 128 channels to detect ERD/ERS during MI (F3, CP3, C3 used) Device: Amadeo, Tyromotion, Austria Control: trigger	MI + kinaesthetic feedback group resulted in higher beta ERS (p=0.02) during rest and higher beta ERD (p=0.04) during MI Kinaesthetic feedback provides higher stability and sustained beta ERD activity than visual feedback
Witkowski et al., 2014 [88]	N=12 (4F:8M) Right-handed Mean age: 28.1±3.63y	Assessment performance and safety of EEG-EOG hybrid BCI	Right hand grasping Cue: visual (coloured squares and arrows) Feedback: kinaesthetic	EEG: 5 channels with EOG and EMG to detect ERD during MI Device: HX hand exoskeleton Actuation: DC motors with Bowden cables for thumb and index fingers Control: trigger	Mean classification accuracies: EEG only = 63.59±10.81% EEG/EOG hybrid = 60.77±9.42% Mean safety criterion violations during rest: EEG only = 45.91±26.8% EEG/EOG hybrid = 10.14±0.3%

Zhang et al., 2019 [89]	N=6 (2F:4M) Right-handed Age range: 23-26y	Implementation of a multimodal system using EEG, EMG and EOG to control a soft-robotic hand	Graz visualisation and auditory instructions, eye movements and physical practice (hand gestures) Cue: visual (Graz MI), auditory Feedback: visual and kinaesthetic	EEG with EMG and EOG: 40 channels to analyse ERD/ERS patterns Device: Soft pneumatic finger Actuation: pneumatic actuator with soft structures Control: trigger	Mean classification accuracies: EOG = 94.23% EEG = 31.46% EMG = 36.38% Multimodal = 93.83±0.02%
