Abstract

Synaptic loss is prominent in several human neurodegenerative diseases. We tested the hypothesis that synaptic density is reduced by the primary tauopathies of progressive supranuclear palsy (PSP-Richardson's syndrome) and corticobasal syndrome (CBS). Thirty-seven participants (12 CBS, 10 PSP, and 15 age-/sex-/education-matched controls) underwent clinical and neuropsychological assessment, 3T magnetic resonance imaging, and positron emission tomography with the radioligand [¹¹C]UCB-J which targets the Synaptic Vesicle Glycoprotein 2A (SV2A). 10 CBS patients had negative β-amyloid biomarkers (Pittsburgh Compound B PET). As expected, patients with PSP-Richardson's syndrome and amyloid-negative CBS were impaired in executive, memory and visuospatial tasks. [¹¹C]UCB-J binding was reduced across frontal, temporal, parietal, and occipital lobes, cingulate, hippocampus, insula, amygdala and subcortical structures in both PSP and CBS patients compared to controls (p<0.001), with reductions up to 50%, consistent with post mortem data. The revised Addenbrooke's Cognitive Examination score correlated positively with [¹¹C]UCB-J binding in frontal, temporal, parietal, occipital, and cingulate cortices, as well as in the hippocampus, insula and amygdala, p<0.05); putamen and frontal lobe [¹¹C]UCB-J binding correlated inversely with the PSP rating scale (p<0.05). In conclusion, we confirm severe synaptic loss in PSP and CBS, which correlates with disease severity, providing critical insights into the underlying pathophysiology of primary degenerative tauopathies and supporting potential treatment strategies based on synaptic maintenance or restoration.

Keywords: Synaptic Vesicle Protein 2A, UCB-J, PET, tauopathy, PSP.

Abbreviations: [¹¹C]UCBJ = (R)-1-((3-(methyl-11C)pyridin-4-yl)methyl)-4-(3,4,5-trifluorophenyl)pyrrolidin-2-one); BP_{ND} = non-displaceable binding potential; PSP = Progressive Supranuclear Palsy, CBS = corticobasal syndrome, CBD = Corticobasal Degeneration; [¹¹C]PiB = (methyl-11C) Pittsburgh compound B; UPDRS = Unified Parkinson's Disease Rating Scale; PSPRS = Progressive Supranuclear Gaze Palsy Rating Scale; ACE-R = Addenbrooke's Cognitive Examination – Revised; MMSE = Mini-mental State Examination; CDR = Clinical Dementia Rating Scale; CBI = Cambridge Behavioural Inventory – Revised; SEADL = Schwab and England Activities of Daily Living Scale. ns = non-significant at p<0.05.

Introduction

The primary degenerative tauopathies of Progressive Supranuclear Palsy (PSP) and Corticobasal Degeneration (CBD) cause a severe combination of movement and cognitive impairment (Litvan *et al.*, 1996; Armstrong *et al.*, 2013; Burrell *et al.*, 2014; Höglinger *et al.*, 2017). Pathologically both are associated with a 4-repeat tauopathy; the underlying pathology of the clinical Corticobasal syndrome CBS is heterogeneous with corticobasal degeneration forming the majority and Alzheimer's disease pathology forming a substantial minority (Alexander *et al.*, 2014). Both PSP and CBD are associated with cortical and subcortical atrophy on magnetic resonance imaging (MRI) (Jabbari *et al.*, 2019); as well as changes in spatiotemporal features of neurophysiology and connectivity measured by magnetoencephalography and functional MRI (Hughes *et al.*, 2014; Wolpe *et al.*, 2014; Cope *et al.*, 2018; Sami *et al.*, 2018).

We proposed that the neurophysiological and connectivity impairments are a consequence of the loss of synapses. For example, at *post mortem* there is approximately 50% loss of cortical synapses in PSP and CBD (Bigio *et al.*, 2001; Lipton *et al.*, 2001). Transgenic models of tauopathies (e.g. rTg4510) confirm a synaptotoxic effect of oligomeric tau, before cell death (Menkes-Caspi *et al.*, 2015; Kaniyappan *et al.*, 2017). Moreover, in other neurodegenerative dementias, such as Alzheimer's disease, synaptic loss correlates better with cognitive dysfunction than atrophy (Terry *et al.*, 1991).

We therefore tested whether PSP and CBD reduce synaptic plasticity *in vivo*, and in proportion to disease severity. We used positron emission tomography (PET) with the radioligand ((*R*)-1-((3-(methyl-¹¹C)pyridin-4-yl)methyl)-4-(3,4,5-trifluorophenyl)pyrrolidin-2-one), known as [¹¹C]UCB-J, manufactured at the Wolfson Brain Imaging Centre Radiopharmaceutical Unit (Milicevic Sephton *et al.*, 2020). This ligand quantifies synaptic density (Finnema *et al.*, 2016, 2017) based on its affinity for the presynaptic vesicle glycoprotein 2A (SV2a), that is ubiquitously expressed in brain synapses (Bajjalieh *et al.*, 1993, 1994). [¹¹C]UCB-J has revealed hippocampal synaptic loss in Alzheimer's disease, correlating with episodic memory loss and clinical dementia severity (Chen *et al.*, 2018). We use β -amyloid biomarkers to identify which cases of CBS are likely to not be caused by Alzheimer's disease pathology (Alexander *et al.*, 2014) and are tentatively considered to have CBD. We sought correlations between regional [¹¹C]UCB-J binding potential, a metric of

SV2A (synaptic) density, and disease severity, in terms of cognitive decline and measures of global impairment.

Materials & Methods

Participants & Study Design

Patients were recruited from a tertiary specialist clinic for PSP/CBS. Healthy volunteers were recruited from the UK National Institute for Health Research Join Dementia Research (JDR) register. Patients had either probable PSP–Richardson Syndrome (Höglinger *et al.*, 2017), or both probable CBS and probable CBD (Armstrong *et al.*, 2013). Participants underwent a clinical and cognitive assessment including measures of disease severity (Table 1), 3T MRI, and [¹¹C]UCB-J PET.

Patients with CBS underwent amyloid PET imaging using carbon 11-Pittsburgh Compound B ([¹¹C]PiB). Only those with a negative amyloid status as characterised by a [¹¹C]PiB standardised uptake value ratio (SUVR; 50-70 minutes post injection; whole cerebellum reference tissue) less than 1.21 (Centiloid scale 19; (Jack *et al.*, 2017)) are included in the subsequent analysis, with the aim of excluding patients with CBS due to Alzheimer’s disease. We interpret this amyloid-negative group as having CBD, although acknowledge that other pathologies are possible.

The research protocol was approved by the local Cambridge Research Ethics Committee and the Administration of Radioactive Substances Advisory Committee. All participants provided written informed consent in accordance with the Declaration of Helsinki.

Neuroimaging

Dynamic PET data acquisition was performed on a GE SIGNA PET/MR (GE Healthcare, Waukesha, USA) for 90 minutes starting immediately after [¹¹C]UCB-J injection (median injected activity: 351 ± 107 MBq, injected mass ≤ 10 μ g), with attenuation correction including the use of a multi-subject atlas method (Burgos *et al.*, 2014; Prados *et al.*, 2016) and also improvements to the MRI brain coil component (Manavaki *et al.*, 2019). Each emission image series was aligned using SPM12 (www.fil.ion.ucl.ac.uk/spm/software/spm12/) then rigidly registered to a T1-weighted MRI acquired during PET data acquisition (TR = 3.6 msec, TE = 9.2 msec, 192 sagittal slices, in plane resolution 0.55 x 0.55 mm (subsequently interpolated to 1.0 x 1.0 mm); slice thickness 1.0 mm). Using a modified Hammersmith atlas with subcortical regions (<http://brain-development.org>), combined regions of interest (in frontal, parietal, occipital, and temporal

lobes; cingulate, and cerebellum) were spatially normalized to the T1-weighted MRI of each participant using ANTs software (Avants *et al.*, 2008), then multiplied by a grey matter binary mask (>50% grey matter on the SPM12 probability map, smoothed to PET spatial resolution). Regional time-activity curves were extracted with and without correction for cerebrospinal fluid (CSF) partial volume using the SPM12 CSF probability map, again smoothed to PET resolution. To quantify SV2A density, [¹¹C]UCB-J non-displaceable binding potential (BP_{ND}) was determined using a basis function implementation of the simplified reference tissue model (Wu and Carson, 2002), with the reference tissue defined in the centrum semiovale (Koole *et al.*, 2019; Rossano *et al.*, 2019). Group average BP_{ND} images (illustrated in Fig1 A-C) were obtained by spatially normalizing individual T1-weighted MRI (and thereby co-registered BP_{ND} map) to MNI space, and then to the group template using ANTS.

Statistical analysis

Statistical analyses used R (version 3.6.2), with analysis of covariance (ANCOVA) to compare regional [¹¹C]UCB-J BP_{ND} between the three groups (Control, CBD, PSP), with age as a covariate of no interest. Regions of interest were: frontal, temporal, parietal, occipital lobes, cingulate cortex, hippocampus, insula, amygdala, putamen, thalamus, cerebellum, and midbrain.

The relationships between [¹¹C]UCB-J BP_{ND}, disease severity (PSP Rating Scale) and cognition (revised Addenbrooke's Cognitive Examination) were tested through linear models of the patient data, with age as a covariate of no interest. All analyses were repeated using CSF uncorrected BP_{ND}.

Data availability

The derived data that support the findings of this study are available from the corresponding author, upon reasonable request for academic (non-commercial) purposes.

Results

Of the twelve patients with CBS, two had PiB SUVR ratios of 2.32 and 1.61 and were therefore excluded from further analysis. The remaining groups (ten CBD, ten PSP, fifteen controls) were matched in age, gender and education (Table 1). We observed typical cognitive profiles, as summarised in Table 1: patients were impaired on memory, verbal fluency, language and visuospatial domains of the ACE-revised, Mini-Mental State Examination and Montreal Cognitive Assessment. There were high endorsements on the Cambridge Behavioural Inventory, and the Clinical Dementia Rating scale, with impairment of activities of daily living on the Schwab and England scale.

The average BP_{ND} map per group is illustrated in Fig.1A-C, alongside a scatter plot of individual regional BP_{ND} values for all participants (Fig. 1D). Regional CSF-corrected BP_{ND} values for the three groups are shown in Table 2. There was a widespread reduction in [^{11}C]UCB-J BP_{ND} in frontal, temporal, parietal, occipital, and cingulate cortex, cerebellum, thalamus, insula, amygdala, caudate nucleus, putamen, and midbrain ($p < 0.05$ FDR corrected). BP_{ND} in PSP and CBD was 30-50% lower than controls, with the most severe median reductions in the midbrain and frontal and parietal lobes of patients with PSP and in the hippocampus, cerebellum and caudate nucleus of patients with CBD. The same pattern of significant reductions in BP_{ND} was observed using CSF-uncorrected data.

Correlations between [^{11}C]UCB-J BP_{ND} , the PSP rating scale and cognition in patients are given in Fig. 2. There were positive correlations between ACE-R and BP_{ND} in widespread cortical and subcortical regions (Fig. 2A; frontal lobe $R^2 = 0.38$, $p = 0.04$; temporal lobe $R^2 = 0.41$, $p = 0.04$; parietal lobe $R^2 = 0.45$, $p = 0.04$; occipital lobe $R^2 = 0.40$, $p = 0.04$; insula $R^2 = 0.41$, $p = 0.04$; cingulate cortex $R^2 = 0.40$, $p = 0.04$; and hippocampus $R^2 = 0.35$, $p = 0.05$; FDR corrected). An inverse correlation was observed between the PSP rating scale and BP_{ND} in the frontal lobe $R^2 = 0.39$, $p = 0.05$, and the putamen $R^2 = 0.25$, $p = 0.049$ (FDR corrected; Fig. 2B). We also observed a negative correlation between [^{11}C]UCB-J BP_{ND} and the Cambridge Behavioral Inventory (marker of global impairment based on carers' rating) in the frontal lobe, $R^2 = 0.3$, $p = 0.04$ (uncorrected). Except for the latter, similar correlations were observed using CSF uncorrected data.

Discussion

The principal result of this study is to confirm a severe reduction in synaptic density in PSP-Richardson's syndrome and amyloid-negative CBS. This accords with *post mortem* estimates of PSP and CBD, using synaptophysin immunohistochemistry, and morphological studies of cortical dendrites in the closely related condition of frontotemporal lobe dementia (Ferrer *et al.*, 1991; Bigio *et al.*, 2001). Indirect evidence of synaptic loss, from consequential reduction in metabolism, comes from [¹⁸F]FDG PET changes in frontal, temporal and parietal lobes (Foster *et al.*, 1988; Eidelberg *et al.*, 1991; Blin *et al.*, 1992; Juh *et al.*, 2004). However, PET imaging with ligand [¹¹C]UCB-J provides direct evidence *in vivo* of severe and extensive loss of cortical and subcortical synapses, including areas of the brain that are minimally atrophic (Josephs *et al.*, 2008).

Progressive supranuclear palsy and corticobasal degeneration are progressive, with an average disease duration of five to eight years from symptom onset (Coyle-Gilchrist *et al.*, 2016). In our clinically diagnosed CBD and PSP groups, the mean symptom duration at the time of PET was three and a half years, and with a pre-symptomatic period, we infer that our patients were likely to be over half-way through their disease course. The median reduction of 20% (and maximal 50%) in [¹¹C]UCB-J binding observed *in vivo* (compared to controls), is in keeping with the predictions from *post mortem* data. Interestingly, the cerebellum was markedly abnormal in CBD. Although cerebellar atrophy is not a typical association of CBS/CBD (Dickson *et al.*, 2007), we suggest this may represent cerebellar diaschisis in response to widespread cortical pathology and loss of cortico-cerebellar projections.

Preclinical models of tauopathy suggest early synaptotoxicity with reduced plasticity and density (Menkes-Caspi *et al.*, 2015), in response to soluble oligomeric tau aggregates (Kaniyappan *et al.*, 2017) and inflammation (Rajendran and Paolicelli, 2018). The toxicity associated with tau pathology leading to synapse loss is complex and involves direct and indirect pathways (reviewed in (Spires-Jones and Hyman, 2014)). Naturally occurring tau plays a role in synaptic function through modulating microtubule and axonal stability; disruptions to this machinery leads to prevention of the trafficking of essential components to synapses such as synaptic receptors (Hoover *et al.*, 2010) and mitochondria. Indeed, over-expression of tau interferes with mitochondria transport (Stoothoff *et al.*, 2009), and

contributes to hyperexcitability of neurons and impaired calcium influx in transgenic mouse models (rTg4510) (Rocher *et al.*, 2010).

Here we observe a significant correlation between synaptic loss and disease severity both in the context of cognitive impairment and physical disability in PSP and CBD. Synaptic loss correlates with cognitive impairment in another clinical tauopathy, Alzheimer's disease (Terry *et al.*, 1991; Robinson *et al.*, 2014), and preclinical models of this (Walsh *et al.*, 2002; Kandimalla *et al.*, 2018). Our in vivo PET results support the potential use of synaptic PET as a marker of disease and progression, but longitudinal data are required. Synaptic PET may support early stage clinical trials in PSP and CBS/CBD; it is encouraging in this latter respect that UCB-J is sensitive to changes in synaptic density in response to treatment with the synaptic modulator Saracatinib (Toyonaga *et al.*, 2019).

Our study has several limitations. Although the sample size is small, it is adequately powered in view of the large effect sizes predicted. However, subtler relationships with mild disease, progression or individual clinical features, or phenotypic variants of PSP and CBS, require larger studies. We acknowledge the potential for off-target binding, but preclinical data indicate very high correlations between UCB-J and synaptophysin, a marker of synaptic vesicular density (Finnema *et al.*, 2016). Our diagnoses were clinical, without neuropathology, although the clinicopathological correlations of PSP-Richardson syndrome are very high, and in the absence of Alzheimer's disease, the clinicopathological correlation of CBS with a 4R-tauopathy (CBD or PSP) is similarly very high (Alexander *et al.*, 2014).

Early stage trials will require early accurate diagnosis, although diagnosis is typically made 3 years after symptom onset (Coyle-Gilchrist *et al.*, 2016; Mamarabadi *et al.*, 2018). It is unlikely that synaptic PET could provide pre-symptomatic diagnosis in rare conditions, but it is a promising tool to characterise pathogenetic mechanisms, monitor progression and assess the response to experimental medicines (Cai *et al.*, 2019).

Table 1. Demographics and neuropsychological profile for each cohort of participants.

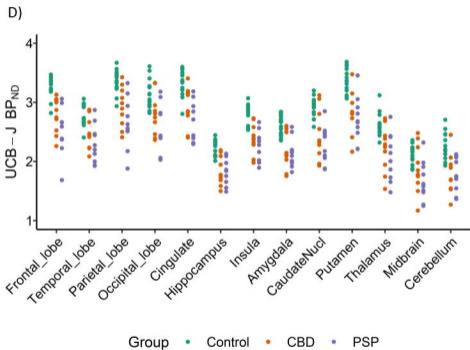

The results are given as mean (standard deviation). ^a chi-squared test. ^b ANOVA with PSP and CBD only. The F-statistic and p-values are derived from an ANCOVA with age as a covariate. UPDRS: Unified Parkinson's Disease Rating Scale, PSPRS: Progressive Supranuclear Palsy Rating Scale, ACE-R: revised Addenbrooke's Cognitive Examination, MMSE: Mini-mental State Examination, CDR: Clinical Dementia Rating Scale, CBI: revised Cambridge Behavioural Inventory, SEADL: Schwab and England Activities of Daily Living

Scale. ns = non-significant at $p < 0.05$; NA = non-applicable. CBD=corticobasal syndrome with evidence of the lack of significant B-amyloid pathology. PSP=PSP-Richardson's syndrome.

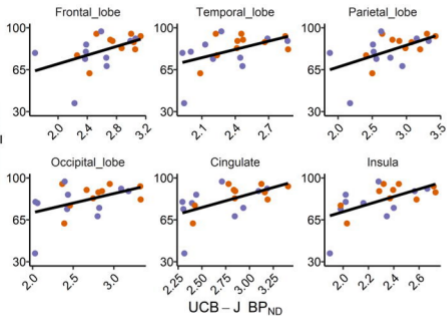

Table 2. Mean (standard deviation) CSF corrected [^{11}C]UCB-J BP_{ND} values per group for cortical and subcortical regions of interest with significant differences across groups (surviving false discovery rate correction over 13 regions).

Region	Control	CBD	PSP	F (p)
Hippocampus	2.22 (0.13)	1.8 (0.24)	1.82 (0.21)	17.00 (0.00001)
Insula	2.83 (0.15)	2.35 (0.25)	2.23 (0.26)	24.7 (0.00001)
Amygdala	2.61 (0.16)	2.12 (0.29)	2.14 (0.24)	16.51 (0.00001)
CaudateNucl	2.92 (0.17)	2.44 (0.38)	2.28 (0.31)	14.96 (0.00003)
Thalamus	2.63 (0.20)	2.21 (0.35)	2.07 (0.40)	9.72 (0.0005)
Putamen	3.39 (0.22)	2.88 (0.31)	2.71 (0.38)	17.25 (0.00001)
Midbrain	2.11 (0.15)	1.89 (0.30)	1.67 (0.33)	6.69 (0.004)
Frontal_lobe	3.26 (0.18)	2.76 (0.29)	2.50 (0.39)	22.34 (0.000001)
Temporal_lobe	2.82 (0.19)	2.45 (0.24)	2.29 (0.32)	14.34 (0.00004)
Parietal_lobe	3.37 (0.19)	2.9 (0.32)	2.65 (0.43)	16.46 (0.00001)
Occipital_lobe	3.15 (0.24)	2.78 (0.29)	2.53 (0.43)	11.2 (0.0002)
Cingulate	3.33 (0.21)	2.85 (0.31)	2.65 (0.35)	17.16 (0.00001)
Cerebellum	2.26 (0.21)	1.88 (0.30)	1.78 (0.29)	12.46 (0.0001)

F-statistic and p-values derived from an ANCOVA across the three groups, with age as a covariate of no interest.
