1 The Coronavirus (COVID-19) epidemic, which was first reported in
2 December 2019 in Wuhan, China, has caused 219,331 confirmed cases as of 20
3 March 2020, with 81,301 cases being reported in China. It has been declared a
4 pandemic by the World Health Organization in 11 March 2020 (1). Although
5 massive intervention measures have been implemented in China (e.g. shutting
6 down cities, extending holidays and travel ban) and many other countries, the
7 spread of the disease are unlikely to be stopped over the world shortly. It is
8 becoming evident that environmental factors are associated with seasonality of
9 respiratory-borne diseases' epidemics (2). Previous studies have suggested that
10 ambient nitrogen dioxide (NO₂) exposure may play a role in the phenotypes of
11 respiratory diseases, including, but not limited to, influenza, asthma and severe
12 acute respiratory syndrome (SARS). NO₂), for example, might increase the
13 susceptibility of adults to virus infections (3). High exposure to NO₂ before the
14 start of a respiratory viral infection is associated with the severity of asthma
15 exacerbation (4). This study aims to assess the associations of ambient NO₂
16 levels with spread ability of COVID-19 across 63 Chinese cities, and provides
17 information for the further prevention and control of COVID-19.

18

19 Methods

20 We collected COVID-19 confirmed case information reported by the

1 National Health Commission and the Provincial Health Commissions of China.
2 We calculated basic reproduction number (R_0) for 63 cities with more than 50
3 cases as of February 10 (COVID-19 peak time in China, including 12 cities in
4 Hubei and 51 cities outside Hubei). The R_0 means the expected number of
5 secondary cases produced by an initial infectious individual, in a completely
6 susceptible population. The calculation process is completed by R software.

7 Hourly NO_2 data were obtained from the National Urban Air Quality
8 Publishing Platform (<http://106.37.208.233:20035/>), which is administered by
9 China's Ministry of Environmental Protection. Daily concentrations of NO_2
10 were calculated as the average of at least 18 (75%) hourly concentrations for all
11 state-controlled stations, then daily NO_2 levels of the city was averaged from all
12 valid stations within it. Other meteorological data including daily mean
13 temperature and relative humidity were collected from the China
14 Meteorological Data Sharing Service System.

15 We conducted a cross-sectional analysis to examine the spatial associations
16 of NO_2 with R_0 of COVID-19, and a longitudinal analysis to examine the
17 temporal associations (day-by-day) of NO_2 with R_0 in the cities in Hubei
18 province since they had enough confirmed case number to acquire stable daily
19 R_0 and the other covariates including health policies were quite similar inside
20 Hubei. We used multiple linear regression to assess the relationship between the
21 spread ability of COVID-19 and NO_2 pollution across the different cities.

1

2 Results

3 Among 63 cities, the mean \pm standard deviation and range were (27.9 \pm 8.3,
4 10.7-53.0) for NO₂ and (1.4 \pm 0.3, 0.6-2.5) for R₀. The top three cities (Wuhan,
5 Huanggang and Yichang) with the highest R₀ were all in Hubei Province.

6 The cross-sectional analysis shows that, after adjustment for temperature
7 and humidity, the R₀ was positively associated with NO₂ in all cities ($\chi^2=10.18$,
8 $p=0.037$). In a following stratified analysis, a significant association was
9 confirmed in the cities outside of Hubei ($r=0.29$, $p=0.046$), while it is not the
10 case in the cities inside Hubei ($r=0.51$, $p=0.130$) (**Figure 1**). We did not find
11 significant associations of temperature and relative humidity with R₀ of
12 COVID-19 ($\chi^2=4.62$, $p=0.372$ and $\chi^2=1.63$, $p=0.804$).

13 In temporal scale, we calculated daily R₀ of 11 cities in Hubei except Wuhan
14 from January 27 to February 26 (there were few COVID-19 confirmed cases in
15 these cities afterwards), and normalized them based on Wuhan's daily R₀ in
16 order to avoid other covariates' effects. We found that the 11 Hubei cities
17 (except Xianning City) all held significant positive correlations between NO₂
18 (with 12-day time lag) and R₀ ($r>0.51$, $p<0.005$), suggesting a positive
19 association between NO₂ and COVID-19 spread ability in the temporal scale
20 (**Figure 2**).

1

2 Discussion

3 Our study was designed to explore the association between the environment
4 factors and the transmission of COVID-19. To our knowledge, this is the first
5 study to investigate the ambient air pollution associated with the transmission of
6 COVID-19. Our results reported the significant association between NO₂
7 exposure and R₀, suggesting that ambient NO₂ may contribute to the spread
8 ability of COVID-19. Previous studies have suggested that the increase spread
9 ability from NO₂ might not be caused by increased susceptibility of the
10 epithelial cells to infection but may result from effects of NO₂ on host defenses
11 that prevent the spread of virus (5). Since NO₂ is a traffic-related air pollutant,
12 the association may also be explained by the relationship between virus spread
13 and population movement. Clearly, further investigations are warranted to
14 provide additional details and illustrate the mechanism.

15 Our study has limitations. Given the ecological nature of study, other city-
16 level factors, such as implementation ability of COVID-19 control policy,
17 urbanization rate, and availability of medical resources, may affect the
18 transmissibility of COVID-19 and confound our findings. Future studies should
19 develop individual based models with high spatial-temporal resolution to assess
20 the correlation between air pollution and epidemiologic characteristics of

1 COVID-19.

3 **Author contributions**

4 Ye Yao, Weibing Wang, and Haidong Kan designed the study. Jinhua Pan,
5 Zhixi Liu, Ye Yao, and Weibing Wang collected COVID-19 incidence data and
6 gained insight into the biology and natural history of the virus. Jinhua Pan,
7 Zhixi Liu., Ye Yao and Weibing Wang developed the model and obtained the
8 related parameters. Weidong Wang and Haidong Kan collected meteorological
9 factors. Ye Yao, Jinhua Pan, Zhixi Liu, and Xia Meng drafted the manuscript.
10 Haidong Kan and Weibing Wang revised the manuscript. All authors critically
11 reviewed and approved the final version of the manuscript.

Supplementary Material

17

Data collection

18

We collected COVID-19 confirmed case information in China reported by

1 the National Health Commission and the Provincial Health Commissions of
2 China. We calculated basic reproduction number (R_0) for 63 cities with more
3 than 50 cases as of February 10 (including 12 cities in Hubei and 51 cities
4 outside Hubei).

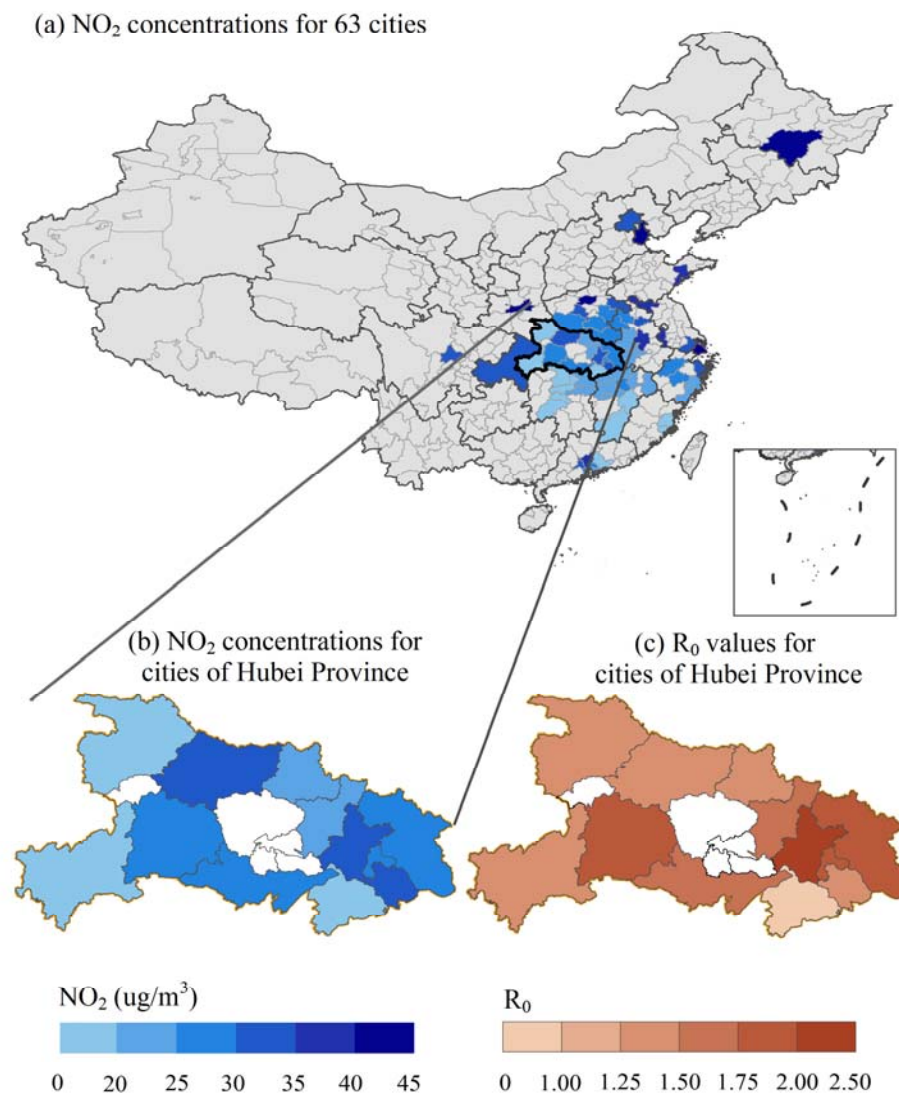

5 Hourly NO_2 data were obtained from the National Urban Air Quality
6 Publishing Platform (<http://106.37.208.233:20035/>), which is administered by
7 China's Ministry of Environmental Protection. Daily concentrations of NO_2
8 were calculated as the average of at least 18 (75%) hourly concentrations for all
9 state-controlled stations, then daily NO_2 levels of the city was averaged from all
10 valid stations within it. Other meteorological data including daily mean
11 temperature and relative humidity were collected from the China
12 Meteorological Data Sharing Service System.

13 **Data analysis**

14 We conducted a cross-sectional analysis to examine the spatial associations
15 of NO_2 with R_0 of COVID-19, and examined the temporal day-by-day
16 associations of NO_2 with R_0 in cities of Hubei province since they had enough
17 confirmed case number to acquire stable daily R_0 and the other covariates
18 including health policies were quite similar inside Hubei. We used multiple
19 linear regression to assess the relationship between the spread ability of
20 COVID-19 and nitrogen dioxide pollution across different cities. The basic
21 reproduction number, denoted R_0 , means the expected number of secondary

- 1 cases produced by an initial infectious individual, in a completely susceptible
- 2 population. if $R_0 < 1$, then the disease free equilibrium is locally asymptotically
- 3 stable; whereas if $R_0 > 1$, then it is unstable. Thus, R_0 is a threshold parameter.
- 4 The calculation process is completed by R software.

5 **Spatial distribution of NO₂**

6

7 **Suppl.Figure1. The spatial Distribution of Average of Nitrogen Dioxide**
8 **Concentration and Spread Ability of COVID-19.**

1 The China map shows the spatial distribution of the average nitrogen dioxide concentration
2 from January 1, 2020, to February 8, 2020, in 63 Chinese cities. And zoom up the "Hubei
3 province" part to compare the trend of the average nitrogen dioxide concentration (gradient
4 blue map, bottom left) with the spatial trend of the basic reproduction number R_0 (gradient
5 brown map, bottom right) in Hubei province.
