17 **ABSTRACT**

18 The novel coronavirus SARS-CoV-2 has emerged as one of the most compelling public health challenges
19 of our time. To address the myriad issues generated by this pandemic, an interdisciplinary breadth of
20 research, clinical, and public health communities have rapidly engaged to find answers and solutions.
21 One area of active inquiry is understanding the mode(s) of SARS-CoV-2 transmission. While respiratory
22 droplets are a known mechanism of transmission, other mechanisms are possible. Of particular
23 importance to global health is the possibility of vertical transmission from infected mothers to infants
24 through breastfeeding or consumption of human milk. However, there is limited published literature
25 related to vertical transmission of any human coronavirus (including SARS-CoV-2) via human milk and/or
26 breastfeeding. There is a single study providing some evidence of vertical transmission of human
27 coronavirus 229E, a single study evaluating presence of SARS-CoV in human milk (it was negative), and
28 no published data on MERS-CoV and human milk. There are 9 case studies of human milk tested for
29 SARS-CoV-2; none detected the virus. Importantly, none of the published studies on coronaviruses and
30 human milk report validation of their analytical methods for use in human milk. These reports are
31 evaluated here, and their implications related to the possibility of vertical transmission of coronaviruses
32 (in particular, SARS-CoV-2) during breastfeeding are discussed.

33 INTRODUCTION

34 The global pandemic caused by the SARS-CoV-2 virus is one of the most compelling and
35 concerning global health crises of our time. Fortunately, this pandemic has rapidly engendered a
36 mobilization of the full range of expertise represented by research, clinical, and public health experts.
37 While our understanding of the biology, clinical implications, and strategies for mitigation continues to
38 evolve, one issue that has received limited attention is the implication of this pandemic for infant
39 feeding practices. This lack of attention has resulted in mixed messages regarding guidance about
40 optimal infant feeding practices^{1,2} and a consequent lack of confidence about the best approaches to
41 infant feeding in the face of this growing pandemic.

42 Several issues related to this topic demand immediate attention, the first and foremost of these
43 being whether or not the virus is present in human milk. Of particular interest in this context are 1) the
44 potential role that breastfeeding could play in vertical transmission of SARS-CoV-2 from women to
45 infants via human milk; and 2) the potential protective effects of targeted antibodies and other
46 immunoprotective components in human milk against COVID-19. The goal of this review is to evaluate
47 the published evidence regarding the presence of this and other human coronaviruses in human milk.

48 METHODS

49 *Search strategy and selection criteria*

50 We used both Google Scholar and PubMed to identify relevant literature published as of April 4,
51 2020. Because some of the reports relating to SARS-CoV-2 have not yet been published in refereed
52 journals (i.e., gray literature), we also used a general Google search and a search of preprint servers
53 bioRxiv and medRxiv. The list of search terms used can be found in **Table 1**. Any research in which
54 human milk was collected and tested for a human coronavirus was included in this review.

55 RESULTS

56 *Overview of vertical transmission of viruses (other than coronaviruses) via human milk*

57 It is well established that viral transmission through human milk can occur.^{3,4} Notable examples
58 include human immunodeficiency virus (HIV),^{5,6} cytomegalovirus (CMV),⁷ and human T-cell lymphotropic
59 virus type 1 (HTLV-1).⁸ Perhaps the most prominent example of mother-to-child viral transmission via
60 breastfeeding is HIV, where higher maternal milk and serum viral loads are associated with an increased
61 risk of transmission.⁹⁻¹¹ The risk of postnatal infection for breastfed infants of HIV+ mothers is ~10-20%
62 over the first 2 years of life.^{12,13} However, compared to mixed feeding, exclusive breastfeeding is
63 associated with lower risk of transmission of HIV infection to infants.^{14,15} In many high-income nations,
64 breastfeeding is contraindicated in the case of maternal HIV infection.^{16,17} However, in low-and-middle-
65 income nations, infant mortality from malnutrition and infectious disease may outweigh the risk of
66 acquiring HIV.^{16,18}

67 With respect to CMV, it is estimated that ~60-70% of breastfed infants of CMV-seropositive
68 infants become infected with CMV.^{19,20} The risk of CMV infection in neonates is highest in preterm or
69 very low birthweight (<1500 g) infants;^{21,22} in a small percentage of infections, infants develop a severe
70 complication known as CMV sepsis-like syndrome, which can be fatal.²³ Nonetheless, breastfeeding is
71 not contraindicated in CMV-seropositive women with healthy, term infants.^{16,24,25}

72 For HTLV-1, breastfeeding is considered the major route of infection for infants.²⁶ HTLV-1
73 infection is lifelong, and while most infected individuals remain asymptomatic, ~10% develop severe
74 disease, including adult T-cell leukemia, a highly aggressive and usually fatal malignancy.²⁷ Some
75 organizations and agencies list maternal HTLV-1 as a contraindication for breastfeeding,^{16,28} while
76 others do not.²⁵

77 ***Human coronaviruses and their vertical transmission***

78 Human coronaviruses are enveloped, positive-sense, single-stranded RNA viruses first described
79 in 1965.²⁹ There are 7 identified strains known to infect humans. Four of the strains (alphacoronaviruses
80 229E, NL63, and OC43; betacoronavirus HKU1) are ubiquitous in humans and cause the common cold.

81 There is limited evidence that one of these (229E) may be vertically transmitted from mothers to infants,
82 although the mechanism remains unclear.³⁰ The presence of 229E in neonatal gastric samples suggests
83 that one possible mechanism for infection is through human milk, although this study³⁰ did not
84 specifically evaluate the presence of 229E in human milk.

85 **SARS-CoV**

86 In addition to those that cause the common cold, more virulent strains of human coronaviruses have
87 emerged zoonotically since the early 2000s, the first being SARS-CoV in 2003. The first reports of SARS-
88 CoV were from China, although the disease (severe acute respiratory syndrome, SARS) quickly spread
89 globally. SARS is clinically manifested by fever, dry cough, headache, muscle aches, and difficulty
90 breathing. No treatment exists except supportive care, but there have been no reports of SARS-CoV
91 transmission since 2004. The case fatality rate of SARS is estimated at 10%.³¹

92 Currently, there is one report in which human milk was tested for SARS-CoV,³² and two reports
93 of human milk being tested for SARS-CoV antibodies.^{32,33} The former is a case study of a woman infected
94 during the second trimester of pregnancy (19 wk). A single milk sample was collected 131 days after the
95 onset of symptoms, but no additional detail on the collection methodologies was provided. Milk was
96 submitted to the US Centers for Disease Control and Prevention (CDC), where it was analyzed using
97 reverse transcriptase polymerase chain reaction (RT-PCR) for viral nucleic acids, and enzyme
98 immunoassay and indirect immunofluorescence to evaluate antibody presence. No additional details on
99 analytical methods were provided. While no viral RNA was detected, antibodies to SARS-CoV were
100 identified in the milk. The infant in this study was never tested for SARS-CoV infection. The latter study
101 was a case report of a 38-yr-old infected in the first trimester of pregnancy (7 wk). She recovered fully
102 and delivered a healthy male infant at 36 wk of gestation. Milk samples were collected at 12 and 30 d
103 postpartum and tested for SARS-CoV antibodies; all were negative. No details on the collection or
104 analysis of the milk were provided. The infant in this study tested negative for SARS-CoV. In both of

105 these studies, it is possible that the women had stopped shedding the virus before the milk samples
106 were collected, as SARS-CoV shedding in other biological samples typically peaks 12-14 d after the onset
107 of disease.³⁴ There are no documented cases of vertical transmission of SARS-CoV between mothers and
108 infants.³⁵

109 **MERS-CoV**

110 A related virus, MERS-CoV, emerged in Saudi Arabia in 2012. The disease caused by MERS-CoV, Middle
111 Eastern respiratory syndrome (MERS), is characterized by severe respiratory illness with symptoms of
112 fever, cough, and shortness of breath. Like SARS-CoV, MERS-CoV is a betacoronavirus. The case fatality
113 rate of MERS is 34%.³¹ There are no reports, to our knowledge, of the presence or absence of MERS-CoV
114 in human milk. However, there are reports of the presence of MERS-CoV in the milk of dromedary
115 camels (*Camelus dromedaries*).³⁶⁻³⁸ There is one report of a human likely infected through the
116 consumption of raw (unpasteurized) camel milk.³⁹ In camel milk samples spiked with MERS-CoV, viable
117 virus could still be recovered after 48 hr.⁴⁰ These two observations have resulted in recommendations
118 against consuming raw, unpasteurized camel milk.⁴¹ It is unclear if there is vertical transmission of
119 MERS-CoV between camelid cows and their calves, and whether infection occurs as a direct result of
120 lactation/nursing in this species. There are no data on vertical transmission of MERS-CoV between
121 women and their infants.^{35,42}

122 **SARS-CoV-2**

123 The novel coronavirus, SARS-CoV-2, was named after SARS-CoV due to its shared sequence homology
124 (77.9%)⁴³ and similar clinical characteristics. The first reported cases of SARS-CoV-2 infection emerged in
125 late 2019 in China. While the case fatality rate for COVID-19 (the disease caused by the SARS-CoV-2
126 virus) is much lower than those of SARS and MERS at ~2%,³¹ the spread of this pathogen has been much
127 more rapid and extensive.

128 At the time of writing, there were 9 studies that reported direct testing of milk produced by
129 women who were infected with SARS-CoV-2⁴⁴⁻⁴⁹ or by women whose infants were infected.⁵⁰⁻⁵² In total,
130 23 milk samples produced by 16 women have been tested; all were negative for the presence of the
131 virus. A description of the relevant characteristics for the women and infants in these studies can be
132 found in **Table 2**. Six of the nine studies analyzed milk samples collected at birth or shortly thereafter,
133 reporting only findings in colostrum or colostrum and transitional milk. Those same six studies reported
134 on the milk produced by women who were infected during the third trimester of pregnancy, while the
135 other three report findings from milk produced by mothers of infants infected at 1.5, 3, and 6 mo of
136 age.⁵⁰⁻⁵² For the infants born to women infected during pregnancy, most were immediately separated
137 from their mothers post-delivery and were not breastfed for the duration of the period observed in their
138 respective reports. Twelve of the 16 infants described in these reports were born via cesarean section,
139 and only one was specified as a vaginal birth. Repeated milk samples were analyzed for 4 of the women,
140 collected up to 16 days apart. All the studies were conducted in China^{44-49,51,52} or Singapore.⁵⁰

141 Wang and colleagues⁴⁴ described a healthy, 34-yr-old woman who acquired the infection in
142 week 40 of pregnancy. She gave birth to a male infant via cesarean section. The infant and his mother
143 both tested positive for SARS-CoV-2 using pharyngeal swabs within 36 hr of the delivery. The infant was
144 separated from his mother at delivery and fed formula for the duration of the period described in the
145 study. The mother's milk was collected at 36 hr postpartum; it tested negative for SARS-CoV-2 via RT-
146 PCR. No description of the collection or testing methods was provided. The authors stated that they
147 recommended that the mother not breastfeed, but instead pump milk to avoid mastitis.

148 In another case series from China, Fan and colleagues⁴⁵ reported on two women who became
149 infected during the third trimester of pregnancy. Patient 1 was 34 yr old and in week 37 of gestation at
150 the time of diagnosis. She delivered a female infant via cesarean section 6 d after testing positive for
151 SARS-CoV-2 via nasopharyngeal swab. The infant was separated from the mother immediately after

152 delivery, and serial tests of the infant’s nasopharyngeal swabs were negative. A milk sample was
153 collected within 24 hr of delivery and 16 d later; both were negative for SARS-CoV-2. Patient 2 was 29 yr
154 old and in week 36 of gestation at the time of diagnosis. Her infant was delivered 5 d after she was
155 diagnosed via RT-PCR analysis of a nasopharyngeal swab. A single milk sample was collected within 24 hr
156 of delivery; it tested negative for SARS-CoV-2. The authors of this report did not specify how the sample
157 was collected, other than “breastmilk was obtained after the first lactation.”

158 Chen and colleague⁴⁶ have provided the most extensive report to date, including data on milk
159 produced by 6 women infected during pregnancy. The women were 26-34 yr-of-age and between 36 wk
160 2 d and 39 wk 4 d of gestation at diagnosis. The authors did not provide details on the methods used for
161 milk collection, other than “breastmilk samples from patients with COVID-19 pneumonia were collected
162 after their first lactation” and that milk was collected following World Health Organization (WHO)
163 guidelines, but they did not provide a citation for this collection method. All milk tested negative for the
164 virus, but no information was provided on the methods used for analysis.

165 In a report by Liu et al.,⁴⁷ milk produced by two women was tested. One woman was 34 yr old
166 and at 40 wk gestation tested positive via oropharyngeal swab. Milk was collected and tested from this
167 women at d 1, 2, and 12 postpartum; all samples were negative. Her male infant was delivered via
168 cesarean and tested for SARS-CoV-2 via oropharyngeal swab when he was 1 and 7 days old; both swabs
169 were negative. The other woman was a 30 yr old and delivered an infant vaginally after testing positive
170 for SARS-CoV-2. Her infant tested negative at birth using an oropharyngeal swab; milk was collected on
171 d 2 postpartum, it was also negative. Details were provided for neither the methods of collection nor
172 analysis.

173 In a research letter by Li and colleagues,⁴⁸ information was provided related to a 30-yr-old
174 woman at 35 wk gestation who was positive for SARS-CoV-2 and delivered a male infant via emergency
175 cesarean section. The infant was tested immediately upon delivery via oropharyngeal swab, which was

176 negative. After delivery, the infant was kept in isolation away from his mother. Milk was collected
177 immediately after delivery and on d 2 and 3 postpartum; all samples were negative. Again, no
178 information on the collection or testing methods for the milk sample is available in this report.

179 In another research letter, Dong and colleagues⁴⁹ report on a 29-yr-old woman at 34 wk of
180 gestation who was diagnosed with COVID-19 via nasopharyngeal swab. Nearly a month later, the
181 woman delivered a female infant via cesarean section. The infant was immediately separated from the
182 mother with no contact. The infant consistently tested negative for SARS-CoV-2 via nasopharyngeal
183 swab over the first 12 d of life. However, a blood sample at 2 hr of age was positive for IgG and IgM
184 antibodies to SARS-CoV-2. A milk sample was collected from the mother at d 6 postpartum; it tested
185 negative. No information on the collection or testing methods for the milk sample is included in this
186 report.

187 While the previous reports focused on infected women, there are also three case studies
188 focused on infected infants. In these studies, milk produced by the infants' mothers was tested for SARS-
189 CoV-2. The youngest of these infants was reported by Cui and colleagues.⁵¹ After being exposed to
190 infected family members, the 55-d-old female was admitted to the hospital with symptoms of COVID-19
191 and diagnosed based on clinical data and exposure history. She was "mixed fed." Her mother's milk was
192 collected on the first 3 consecutive days of her hospitalization; all milk samples tested negative for SARS-
193 CoV-2. No information on the collection or testing methods for the milk sample is included in this report.
194 Yuehua and colleagues⁵² reported on a 3-mo-old, breastfed female who was hospitalized and tested via
195 throat swab for SARS-CoV-2; the swab was positive. A single milk sample was collected from the infant's
196 mother; it tested negative. The authors provided no information on the collection or testing methods for
197 the milk. Importantly, this infant developed symptoms of COVID-19 7 d before her parents did. As such,
198 one possibility is that she was infected first and passed the infection to them. Another case report on a
199 mature milk sample comes from Singapore.⁵⁰ This report is particularly interesting as the infant had no

200 symptoms but was hospitalized and tested because his caregivers were all hospitalized with COVID-19
201 and there was no one to care for him. The infant was 6 mo old and presumably at least partially human
202 milk fed as a sample of milk was successfully collected from his mother. Despite being asymptomatic, a
203 nasopharyngeal swab taken from the infant was positive for SARS-CoV-2. The authors reported that milk
204 produced by the mother on a single day tested negative for the virus but do not specify how many
205 samples were taken. This report provided no data on the methods used for the collection and analysis of
206 these sample(s).

207 **DISCUSSION**

208 Despite the devastating clinical manifestations of SARS-CoV, MERS-CoV, and SARS-CoV-2, there remains
209 much to be learned about their modes of transmission. Respiratory droplets are a documented source
210 of the virus, but other sources such as human milk may exist. The primary purpose of this review was to
211 examine the evidence (or lack, thereof) for the vertical transmission of SARS-CoV-2 from mother to
212 infant via breastfeeding considering what is known about other human coronaviruses.

213 There are currently 9 studies available on SARS-CoV-2 and human milk, collectively
214 encompassing at least 23 milk samples, all of which tested negative for SARS-CoV-2. There are no
215 comparable data for MERS, and a single case report for SARS, which yielded a negative result for the
216 presence of the virus but positive results for antibodies specific to SARS-CoV. There have been no
217 antibody tests in milk specific to SARS-CoV-2 in any of the reports to date, although one paper reported
218 on SARS-CoV-2 antibodies in infant serum which were likely transplacental and thus maternal in origin.⁴⁹
219 This remains a critical area that must be addressed to fully understand the role, if it exists, of
220 breastfeeding and the feeding of human milk in infant infection.

221 The presence of viable MERS-CoV in camel milk is suggestive of the possibility that SARS-CoV-2
222 could be present and viable in human milk (or that of other species; to date, the authors are unaware of
223 any such reports). Notably, Reusken and colleagues³⁶ reported that milk was not collected from camels

224 aseptically; rather, samples were obtained according to local milking customs. As such, it is possible that
225 the presence of MERS-CoV in camel milk could be due to contamination from the milker, the calf, or the
226 environment, rather than milk representing an endogenous source of the virus. However, the limited
227 data available on all three of these viruses (and human coronaviruses, in general) leave many questions
228 unanswered with respect to the role, if any, of human milk in vertical transmission of coronaviruses.

229 One possible reason that the RT-PCR results for all the milk samples tested were negative is that
230 the methods used were neither designed nor validated for human milk. Milk is a complex matrix
231 containing substantial fat, DNases,⁵³ and RNases,⁵⁴⁻⁵⁶ and other PCR inhibitors.⁵⁷⁻⁵⁹ Thus, validation of
232 methods using human milk is needed. In addition, other than general statements about the timing of
233 collection (e.g., “milk was collected after the first lactation”) and brief descriptions of the RT-PCR assays
234 used for nasal and throat swabs, none of the studies to date has described the methods of collection
235 and how the milk was handled and stored in any detail. Of note is the fact that commonly used silica
236 column-based RNA isolation methods are designed for a limited sample volume, and as such are not
237 suitable for more voluminous liquid samples. In addition, nothing is known about stability of SARS-CoV-2
238 in human milk and how quickly (or at what temperature) it must be frozen to preserve fidelity.
239 Information on sample collection, handling, and storage is critical to evaluating whether the negative
240 results described in these studies could be due to inadequate methods used.

241 Another possibility is that there is low abundance of the virus in human milk, and it has simply
242 not been captured in the limited samples tested so far. For example, in the report on other human
243 coronaviruses by Gagneur and colleagues,³⁰ 159 maternal-infant dyads were tested (including 161
244 infants, two sets of twins). In this report, 229E was present in both maternal and infant samples in only 2
245 dyads. Additionally, in the milk of dromedary camels, MERS-CoV appears to be present at very low
246 abundance.³⁶ This suggests the possibility that very low viral load in milk might also lead to an inflation
247 of false negatives.

248 From the limited data on SARS-CoV, it appears that the presence of antibodies in milk could be
249 influenced by timing of infection, where antibodies to SARS-CoV were detected only in milk produced by
250 a woman who acquired the infection later in pregnancy. While the methods used to test this milk were
251 not fully described, this observation could have impacts on the clinical management of infants born to
252 women diagnosed with COVID-19 during pregnancy and/or lactation. This observation is also supported
253 by the findings of Dong and colleagues⁴⁹ who reported that both IgG and IgM antibodies to SARS-CoV-2
254 were present in the serum of an infant at 2 hr of age, despite multiple negative RT-PCR tests of
255 nasopharyngeal swabs over the first days of life. The presence of antibodies at such an early stage of life
256 could indicate transfer of SARS-CoV-2-specific antibodies from mother to infant during gestation. It is
257 noteworthy that IgM antibodies⁴⁹ present in the serum of SARS-CoV-2 negative infants cannot cross the
258 placental barrier.⁴⁹ Together, these observations suggest infant infection *in utero*, but that the virus may
259 simply be absent from the upper respiratory tract immediately after birth.

260 Very recent work has demonstrated that, like SARS-CoV and human coronavirus NL63,⁶⁰
261 angiotensin-converting enzyme 2 (ACE2) is one of the receptors used by SARS-CoV-2 to enter host
262 cells.⁶⁰⁻⁶² ACE2 is expressed across many body sites and tissue types, including the oral cavity (e.g.,
263 tongue and oral mucosa) and in mammary tissue.⁶³ If mammary epithelial cells express this receptor,
264 then it follows that viable virus could exist in milk. If it does, then the introduction of virus-containing
265 human milk could represent a mechanism of entry for SARS-CoV-2 and COVID-19 infection for infants.

266 Another observation worth considering is that in at least one of the reports⁵² the infant was
267 infected and symptomatic 7-8 days prior to the infant's parents. This suggests the possibility that a
268 "reverse" vertical transmission from infant to mother could occur, a phenomenon which has been
269 observed for other pathogens, such as HIV^{64,65} and Ebola virus.⁶⁶ One possible mechanism for maternal
270 infection in this case is through retrograde flow, where milk and saliva move back into the mammary
271 gland from the infant's mouth during suckling.⁶⁷ While this mechanism is speculative, it represents a

272 possible route whereby an infant could theoretically transfer a pathogen it has encountered in the
273 environment to the mother. It is also possible that maternal infection could occur through other
274 mechanisms, such as infant respiratory droplets⁶⁸ or via fecal matter.⁶⁹

275 **CONCLUSIONS**

276 Human milk is the gold standard for infant feeding. However, confidence with regard to its
277 safety and best practices around breastfeeding during maternal COVID-19 infection has been
278 compromised by the lack of evidence as to whether SARS-COV-2 can be vertically transmitted in milk
279 and/or during breastfeeding. As such, there exists an immediate need to rapidly generate rigorous
280 evidence for the role (if any) of human milk and breastfeeding in vertical transmission of COVID-19 from
281 mothers to infants. To accomplish this, validation of analytical methods for the human milk matrix,
282 viability testing, and evaluation of other immune components in milk will all be critical to this effort,
283 especially given the known protective effects of breastfeeding in other infant respiratory infections.^{70,71}
284 Substantial interdisciplinary research on this topic is required and should be performed rigorously and
285 rapidly to best inform policies regarding early feeding choices and clinical management of breastfeeding
286 mothers infected with SARS-CoV-2 and their infants.

287

288 **ACKNOWLEDGEMENTS**

289 The authors acknowledge the generous gift by the Family Larsson-Rosenquist Foundation (FLRF) in
290 support of UC San Diego's MOMI CORE.

291 **AUTHORS CONTRIBUTIONS**

292 KAL, RMP, and JEW performed the literature search. KAL wrote the first draft. All authors read and
293 contributed to the final manuscript.

294 **CONFLICT OF INTEREST STATEMENTS**

295 The authors declare no conflicts of interest.

296 **ROLE OF FUNDING SOURCE**

297 There was no funding source associated with this article.

298 **ETHICS COMMITTEE APPROVAL**

299 Ethics committee approval was not required for this review article.

Table 1. Search terms used in combination to identify existing literature reporting the possibility of vertical transmission of coronaviruses from mother to infant during breastfeeding. Google Scholar and PubMed were searched to identify literature published as of April 4, 2020. Preprint servers bioRxiv and medRxiv were also searched to identify preliminary reports that have not undergone the traditional peer-review process.

Abbreviations: NS, not specified; NA, not applicable

¹The infant's breastfeeding status was not specified in the report, but it is presumed that he was at least partially breastfed as the mother was producing milk at 6 mo postpartum.

²Study presented data from 9 women but only had data on the milk produced by 6 women.

³Gestational age upon admission.

⁴Study presented data from 3 women but only had data on the milk produced by 2 women.
