16 **ABSTRACT**

17

18 Several studies have demonstrated the advantages of environmental surveillance through the
19 monitoring of sewer systems for the assessment of viruses circulating in a given community
20 (wastewater-based epidemiology, WBE).

21 During the COVID-19 public health emergency, many reports have described the presence of SARS-
22 CoV-2 RNA in stools from COVID-19 patients, and a few studies reported the occurrence of SARS-
23 CoV-2 in wastewaters worldwide. Italy is among the world's worst-affected countries in the COVID-
24 19 pandemic, but so far there are no studies assessing the presence of SARS-CoV-2 in Italian
25 wastewaters. To this aim, twelve influent sewage samples, collected between February and April
26 2020 from Wastewater Treatment Plants in Milan and Rome, were tested adapting, for concentration,
27 the standard WHO procedure for Poliovirus surveillance. Molecular analysis was undertaken with
28 three nested protocols, including a newly designed SARS-CoV-2 specific primer set.

29 SARS-CoV-2 RNA detection occurred in volumes of 250 mL of wastewaters collected in both areas
30 at high (Milan) and low (Rome) epidemic circulation, according to clinical data. Overall, 6 out of 12
31 samples were positive. One of the positive results was obtained in a Milan wastewater sample
32 collected a few days after the first notified Italian case of autochthonous SARS-CoV-2.

33 The study shows that WBE has the potential to be applied to SARS-CoV-2 as a sensitive tool to study
34 spatial and temporal trends of virus circulation in the population.

35

36 INTRODUCTION

37

38 Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) is responsible for the coronavirus
39 disease COVID-19, a public health emergency worldwide. On March 11 2020, the World Health
40 Organization declared COVID-19 a pandemic. Italy is among the world's most affected countries in
41 the COVID-19 pandemic. Indeed, after entering Italy, COVID-19 has been spreading fast. As of April
42 20th 2020, the total number of cases reported by the authorities reached 181,228, with 108,237 active
43 cases (Dipartimento della Protezione Civile, Bulletin 20.04.2020), mainly located in Northern Italy
44 (Lombardy, and its neighbouring regions of Emilia-Romagna and Piedmont).

45 Presymptomatic and paucisymptomatic carriers, mostly undetected in clinical and laboratory
46 surveillance systems, contribute to the spread of the disease (Bay et al., 2020; Nicastri et al., 2020;
47 Rothe et al., 2020; WHO, 2020) and hamper the efforts made to assess the extent of SARS-CoV-2
48 circulation in the population and to control efficiently virus transmission. Analytical regular
49 investigation of wastewaters provides valuable information to measure viral circulation in the
50 population as Wastewater Treatment Plants (WWTPs), collecting and concentrating human excreta,
51 are useful sampling points receiving discharges from the entire community.

52 Environmental microbiologists have studied pathogens in sewage for decades (La Rosa & Muscillo,
53 2012; Sinclair *et al.*, 2008). The screening of wastewater, as a public health surveillance tool, defined
54 as wastewater-based epidemiology (WBE), is currently well recognized (Xagorarakis & O'Brien,
55 2020). In the recent years, scientists have applied WBE to a wide range of waterborne, foodborne and
56 fecal-oral viruses, which infected individuals usually excrete in high concentration with faeces
57 (Katayama et al., 2008; Iaconelli et al., 2017; Bisseaux et al., 2018). However, the concept of WBE
58 can also be applied to viruses beyond those commonly associated with the faecal-oral route (i.e.
59 enteric viruses), since viral shedding may involve different body fluids ultimately discharged into
60 urban sewage.

61 Some studies have reported the presence of virus RNA in the stools of COVID-19 patients in
62 percentages ranging from 16.5% to 100% at a concentration up to 6.8 log₁₀ genome copies/g of stool
63 (Chen et al., 200; Lo et al., 2000; Han et al., 2000; Lescure et al., 2000). Furthermore, preliminary
64 studies have reported the detection of SARS-CoV-2 RNA in wastewater in The Netherlands (Medema
65 *et al.*, 2020), France (Wurtzer et al., 2020), USA (Wu et al., 2020), and Australia (Ashmed et al.,
66 2020). To date, no study has yet provided insights into the presence of SARS-CoV-2 in wastewaters
67 in Italy.

68 Herein we report the results of the screening for SARS-CoV-2 presence in sewage samples collected
69 between the end of February and the beginning of April 2020 from WWTPs in Milan (Northern Italy)
70 and Rome (Central Italy).

71

72

73

74 **MATERIAL AND METHODS**

75

76 Twelve raw sewage samples were collected between the 3rd of February and the 2nd of April 2020
77 from three WWTPs, located in Milan (two distinct plants, reported as A and B) and in Rome (one
78 plant receiving two different pipelines, C1 and C2, from different districts of the town), respectively.

79 The samples (24-hour composites) were collected from the WWTP influent, immediately stored at -
80 20 °C, and dispatched frozen to the National Institute of Health for analysis. Before viral
81 concentration, samples underwent a 30 min treatment at 57 °C to increase the safety of the analytical
82 protocol for the laboratory personnel and environment, as Pastorino et al. (2020) reported these
83 conditions to reduce the virulence of the virus by over 5 log.

84 Sample concentration took place using a two-phase (PEG-dextran method) separation as detailed in
85 the 2003 WHO Guidelines for Environmental Surveillance of Poliovirus protocol (WHO, 2003), with
86 modifications to adapt the protocol to enveloped viruses. In brief, the wastewater sample (250 mL)

87 was centrifuged to pellet the wastewater solids, retaining the pellet for further processing. The
88 clarified wastewater was mixed with dextran and polyethylene glycol (PEG), and the mixture was
89 left to stand overnight at 4 °C in a separation funnel. The bottom layer and the interphase were then
90 collected drop-wise, and this concentrate was added to the pellet from the initial centrifugation. The
91 chloroform treatment that the WHO protocol envisages at this stage was omitted; this preserved the
92 integrity of the enveloped viruses object of this study. The viral nucleic acids extraction foresaw the
93 use of the NucliSENS miniMAG semi-automated extraction system with magnetic silica carried out
94 following manufacturer's instructions (bioMerieux, Marcy l'Etoile, France) with however slight
95 modifications. The lysis phase was prolonged to 20 minutes, and brief centrifugation ($2000 \times g$, 1
96 min) was used to pellet the sediment; subsequently, magnetic silica beads were added to the cleaned
97 supernatant. Before molecular tests, the extracted nucleic acids were further purified by PCR
98 inhibitors using the OneStep PCR Inhibitor Removal Kit (Zymo Research, CA, USA).

99 In the absence of a standardized method for SARS-CoV-2 detection in environmental samples, RNAs
100 were tested for the presence of SARS-CoV-2 using three different PCR assays (Table 1 and Figure
101 1):

- 102 a) a broad range of PCR for Coronavirus detection targeting the ORF1ab (Ar Guilh et al.,
103 2018). Primers were previously designed targeting a highly conserved region (nsp12) among
104 all Coronavirinae sequences to detect a broad range of coronaviruses by a semi-nested PCR
105 producing a fragment of 218 bp.
- 106 b) a newly designed primer set specific for SARS-CoV-2. Novel nested primers, amplifying a
107 332 bp fragment of ORF1ab, were designed using prime3 software (<http://primer3.ut.ee/>).
108 For the assays a) and b) first-strand cDNA was synthesized using Super Script IV Reverse
109 Transcriptase (ThermoFisher Scientific) with the reverse primer. PCR reaction was
110 performed using 2.5 µl of cDNA in a final volume of 25 µl (Kit Platinum™ SuperFi™ Green
111 PCR Master Mix, Thermo), using 1 µl of primers (10 µM). The PCR conditions were as
112 follows: 98 °C for 30 sec; 35 cycles of 98 °C for 10 sec, 50 °C and 54 °C for 10 sec for assay

113 a) and b) respectively, and 72 °C for 30 sec; final extension 72 °C for 5 min. After the first
114 round PCR, nested PCR was performed using 2 µl of first PCR product and under the same
115 reaction composition and thermal profile conditions. A synthetic DNA (Biofab Research)
116 including the PCR target region, was used to set up PCR conditions before experiments with
117 study samples, but was not amplified along with samples to avoid risks of PCR contamination
118 . Molecular grade water was used as the negative control.

119 c) a published nested RT-PCR for SARS-CoV-2 targeting the spike region (Nao et al., 2020).
120 cDNA was synthesized from 5 µl of sample RNA, using SuperScript III Reverse
121 Transcriptase (ThermoFisher Scientific), 0.5 µM of the reverse primer (WuhanCoV-spk2-r,
122 Table 1) and a 50 min reaction at 50 °C (20 µl final volume). First PCR reaction was
123 performed by adding the reaction mix (Dream Taq polymerase and buffer from ThermoFisher
124 Scientific, 0.4 µM of primers WuhanCoV-spk2-r and WuhanCoV-spk1-f) directly to the
125 whole volume of synthesized cDNA. The used PCR conditions were as follows: 95°C for 1
126 min; 35 cycles of 95 °C for 30 sec, 56 °C for 30 sec, and 72 °C for 40 sec; final extension 72
127 °C for 5 min. Nested PCR (primers NIID_WH-1_F24381 and NIID_WH-1_R24873) was
128 performed in a total volume of 50 µl using 5 µl of first PCR product, with the same conditions
129 applied for the first PCR and 45 cycles.

130 All positive samples were retested for confirmation of results. The PCR products were revealed by
131 electrophoresis on 2% agarose gels and were purified using a Montage PCRm96 Microwell Filter
132 Plate (Millipore, Billerica, MA, USA) and then direct sequenced on both strands (BioFab Research,
133 Rome, Italy). Sequences were identified in terms of the closest homology sequence using BLAST
134 <https://blast.ncbi.nlm.nih.gov/Blast.cgi>. All Italian SARS-CoV-2 genome sequences available at the
135 time of analysis were retrieved from GISAID (<https://www.gisaid.org/>) for comparison with study
136 sequences, using the MEGA X software (Kumar *et al.*, 2018)..

137 Sequences were submitted to NCBI GenBank with the accession numbers: [GenBank submission ID
138 2337138 and 2337168].

139

140 **RESULTS AND DISCUSSION**

141

142 The 50% (6/12) of the wastewater samples showed positive results for SARS-CoV-2 RNA (Table 2).

143 Both the published and newly designed SARS-CoV-2 specific primer sets detected bands of the

144 expected size and were confirmed by the sequencing. In contrast, only aspecific products were

145 detected with a broad range assay for coronavirus. Upon comparison of broad range primers with

146 SARS-CoV-2 genome, we noted that they showed only 77.1 to 91.3 % nt identity, which explain why

147 these were not able to amplify the novel coronavirus.

148 SARS-CoV-2 RNA was first detected with a weak amplification signal in an influent sample from

149 Milan WWTPs (Lombardy, North Italy) collected on February 24th from the plant A with the ORF1ab

150 assay. A positive result for SARS-CoV-2 was also detected this time with a strong amplification

151 signal, on February 28th from the plant B, with both the ORF1ab and the Spike regions. In the influent

152 samples taken from the WWTP in Rome (Latium, Central Italy), SARS-CoV-2 was detected in both

153 the sampling dates (31st of March and 2nd of April) and both the pipelines, C1 and C2, using the newly

154 designed primer sets specific for SARS-CoV-2. The analyzed sequences showed, for both ORF1ab

155 and S partial gene regions, 100% identity with the first SARS-CoV-2 sequence detected in Italy

156 (MT066156), isolated on 30th January 2020 from a Chinese tourist by the Institute “Lazzaro

157 Spallanzani” (INMI, Rome). Given the high level of conservation of the two analysed regions, 100%

158 identity was also detected with several sequences in GenBank and with all the other Italian SARS-

159 CoV-2 genomes deposited in Gisaid.

160 Significantly, on February 24th and 28th, when the samples positive for SARS-CoV-2 were collected

161 in Milan, COVID-19 infections were still limited in Italy, the first Italian autochthonous SARS-CoV-

162 2 positive case having been reported only a few days earlier, on February 21st. On February 28th, the

163 total number of SARS-CoV-2 positive patients reported in all Italy was only 888, with 531 (57%) in

164 Lombardy, the most affected region in the country. However, at that time, the vast majority of cases

165 in Lombardy were recorded in the provinces of Lodi, Cremona and Bergamo (182, 123, and 103
166 cases, respectively). In comparison, in the province of Milan (an even larger area compared to the
167 metropolitan area served by the selected WWTPs) only 29 cases had been reported (Dipartimento
168 della Protezione Civile, Bulletin 28.02.2020).

169 These results provide evidence of the sensitivity of environmental surveillance for the detection of
170 ongoing outbreaks in the population. Virus detection in sewage, despite the low incidence of reported
171 human infections, may be associated with the ability of environmental surveillance to detect mild,
172 subclinical, or asymptomatic cases. These infected individuals shed viruses into local sewage systems
173 and contribute to virus circulation while remaining substantially undetectable by clinical surveillance,
174 a phenomenon known as the “surveillance pyramid” (Martinez Wassaf et al., 2014). Clinical
175 surveillance, indeed, only captures the tip of the iceberg of viral diseases (hospitalized patients or
176 laboratory diagnosed cases). In contrast, monitoring of urban wastewaters makes it possible to capture
177 the full extent of the diseases at a community level.

178 As regards to the influent samples collected in Rome, SARS-CoV-2 detection was obtained on March
179 31, when the epidemic had spread considerably in Italy. In that date, a total of 77.635 SARS-CoV-2
180 infections had been reported in Italy, of which 3.095 in Latium Region and 2.186 in the province of
181 Rome (Dipartimento della Protezione Civile, Bulletin 31.03.2020), with about 85% of them being
182 active cases (Assessorato alla Sanità e all’Integrazione Socio Sanitaria della Regione Lazio; Ministero
183 della Salute, Bulletin 31.03.2020). Given this diffusion of the virus, with such several excreting
184 patients (symptomatic and asymptomatic), the detection of the viral RNA in the tested samples is not
185 surprising and, consistently, the samples taken two days later, on the 2nd April, at the same WWTP
186 were still positive for SARS-CoV-2 RNA.

187 Following this investigation on the occurrence of SARS-CoV-2 RNA in sewage, the production of
188 quantitative data on virus concentration in raw sewage will be undertaken. This approach will allow
189 obtaining a rough estimation of the total number of subjects excreting the virus, by integrating - as
190 done by Wu and co-workers in samples taken in the United States (Wu et al., 2020) - the available

191 information on viral shedding rates, WWTPs loads, and virus concentration in wastewaters.
192 Moreover, the environmental surveillance will be extended to the collection of wastewater samples
193 available in the Department of Environment and Health of the Italian National Health Institute, that
194 were collected throughout Italy in the framework of different projects on enteric viruses. Such
195 monitoring will provide a picture of the SARS-CoV-2 circulation across the different regions of Italy
196 and over time, to better understand the virus circulation, as provided by wastewater-based
197 epidemiology (WBE) and compare it to the clinical data. Samples collected before the reporting of
198 the first known Italian case on February 21 will also be tested, to possibly infer when SARS-CoV-2
199 first appeared in Italy. In a previous study, indeed, wastewater monitoring provided evidence that a
200 novel variant of Norovirus GII.17 (termed Kawasaki 2014) had been circulating in the Italian
201 population before its first appearance and identification in clinical cases, later becoming one of the
202 prevalent variants in the population (Suffredini et al., 2018).

203 Also and most important, environmental monitoring of SARS-CoV-2 in sewages will continue when
204 the emergency phase is over, and its circulation in the population will be considered limited. Indeed,
205 sewage surveillance could also serve for the early detection of a possible re-emergence of COVID-
206 19 in urban areas. WHO recommends environmental surveillance for poliovirus as an early warning
207 system. As an example, during 2013, Israel observed the silent reintroduction and transmission of
208 wild poliovirus type 1, detected through routine environmental surveillance performed on sewage
209 samples (https://www.who.int/csr/don/2013_09_20_polio/en/) without the reporting of any clinical
210 cases. Environmental monitoring, therefore, appears to be an effective measure for proving early
211 warning against pathogen reintroduction.

212 In conclusions, the main findings of this study are:

- 213 1) first detection of SARS-CoV-2 RNA fragments in sewage in Italy;
- 214 2) demonstration of the suitability of the WHO protocol for sewage treatment to enveloped
215 viruses after appropriate modifications;
- 216 3) design of a novel nested PCR assay specific for SARS-CoV-2, useful for screening purposes.

217 Further research will clarify the applicability of WBE to SARS-CoV-2 for prompt detection, the
218 study, and the assessment of viral outbreaks.
