12 **ABSTRACT**

13
14 Objectives: To provide the first known comprehensive analysis of COVID-19 outcomes in a
15 federal penitentiary system. We examined the following COVID-19 outcomes within federal
16 penitentiaries in Canada and contrasted them with estimates for the overall population in the
17 penitentiaries' respective provincial jurisdictions: testing, prevalence, the proportion recovered,
18 and fatality.

19
20 Methods: Data for prisons were obtained from the Correctional Service of Canada and, for the
21 general population, from the Esri COVID-19 Canadian Outbreak Tracking Hub. Data were
22 retrieved between March 30 and April 21, 2020, and are accurate to this date. Penitentiary-,
23 province- and sex-specific frequency statistics for each outcome were calculated.

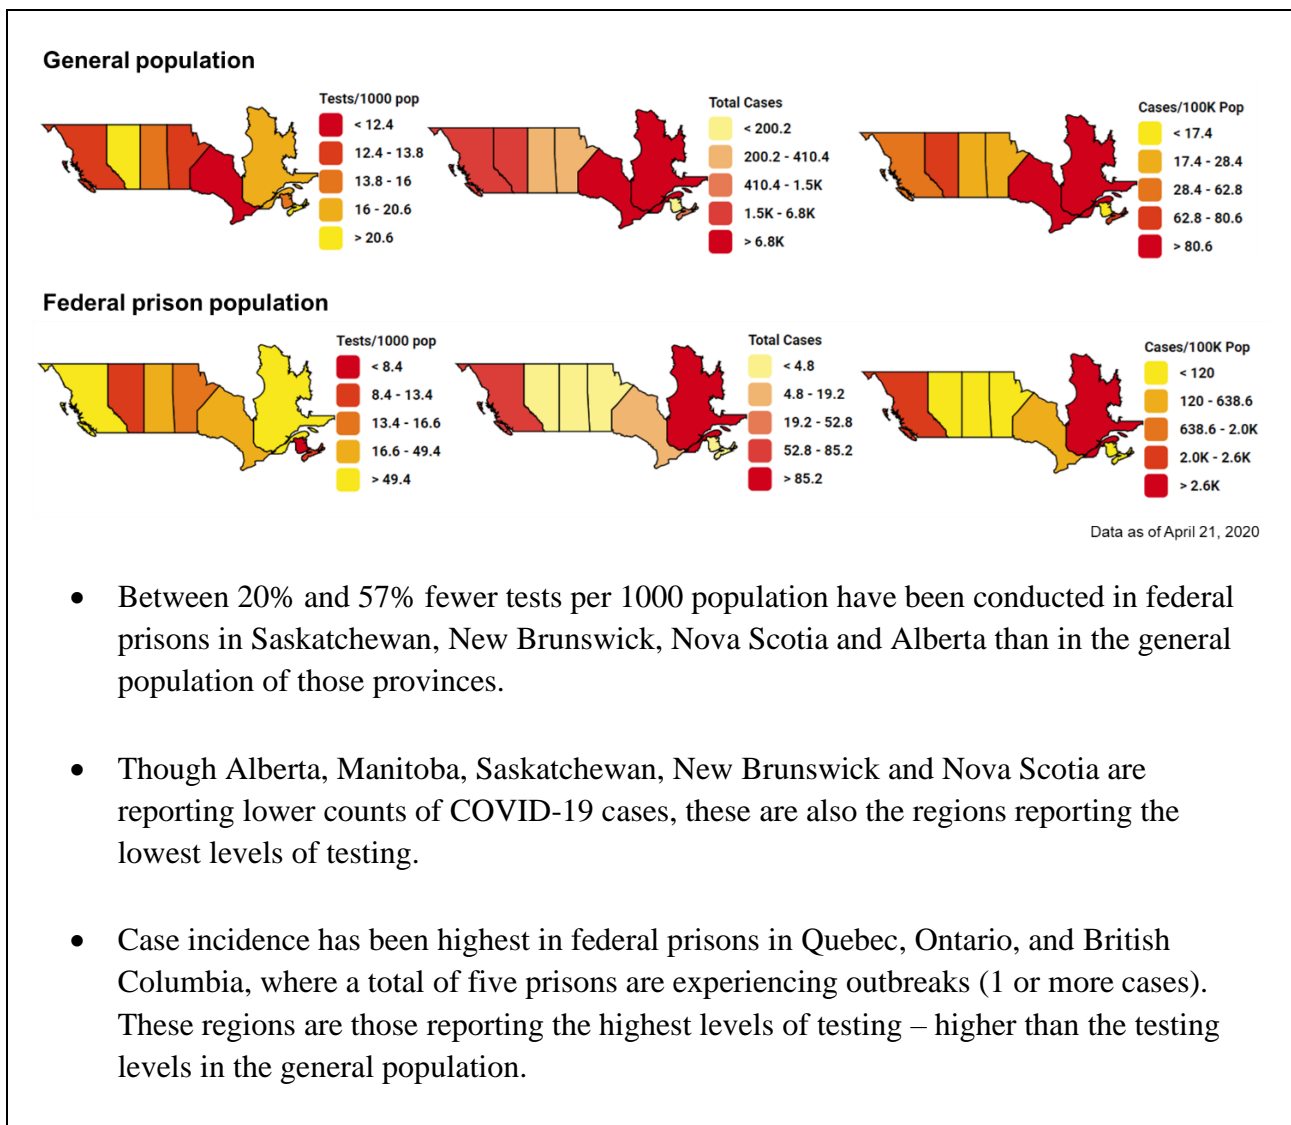

24
25 Results: Data on 50 of 51 penitentiaries (98%) were available. Of these, 72% of penitentiaries
26 reported fewer tests per 1000 population than the Canadian general population average (16
27 tests/1000 population), and 24% of penitentiaries reported zero tests. Penitentiaries with high
28 levels of testing were those that already had elevated COVID-19 prevalence. Five penitentiaries
29 reported an outbreak (at least one case). Hardest hit penitentiaries were those in Quebec, Ontario,
30 and British Columbia, with some prisons reporting COVID-19 prevalence of 30% to 40%. Of
31 these, two were women's prisons. Female prisoners were over-represented among cases (31% of
32 cases overall, despite representing 5% of the total prison population).

33
34 Conclusion: Increased sentinel or universal testing may be appropriate given the confined nature
35 of prison populations. This, along with rigorous infection prevention control practices and the
36 potential release of prisoners, will be needed to curb current outbreaks and those likely to come.

48 **1. BACKGROUND**

49
50 As we are (re)learning from the evidence of COVID-19 outbreaks in long-term care facilities,
51 housing large groups of individuals in confined, institutionalized environments is a recipe for
52 large-scale, human-to-human transmission of infectious disease. Prisons have similar dynamics
53 of confinement, of residents who are dependent on the institutions' conditions and policies for
54 basic living and hygiene and, of clinical susceptibility due to underlying health conditions [1-3].
55 Epidemiologic findings from past outbreaks of respiratory diseases such as influenza,
56 adenoviruses, and tuberculosis in high-income countries highlight the higher likelihood of
57 infection transmission and disease incidence within prisons compared to the general population.
58 [1-3]. Early reports suggest that several penitentiaries in the United States are experiencing
59 COVID-19 outbreaks [4], though, as far as we know, no comprehensive analysis of these
60 penitentiaries has yet been conducted, and very little is known about COVID-19 in prison
61 contexts in other high-income countries. In this study, we use Canadian data to provide the first
62 known examination of COVID-19 statistics for a federal penitentiary system. In doing so, we
63 also bring front-and-center a major health equity issue, because Indigenous and racialized
64 communities are over-represented within the Canadian prison system [5].

65
66 In the context of the COVID-19 pandemic, there are specific factors that place prisoner
67 populations at particularly high risk of COVID-19 infection, and of a higher risk for severe
68 (compared to mild) COVID-19 outcomes. These include housing multiple prisoners to one cell
69 (“double-bunking”)[6], the ageing population within prisons—particularly in federal prisons[7],
70 a high prevalence of chronic disease comorbidities and immuno-compromised health status
71 associated with substance use and blood-borne infections[8], and the regular entrance of
72 custodial and health care staff from communities with likely community-based transmission.

73
74 At the time of writing (late April 2020), Canada has been documenting the COVID-19 pandemic
75 on its soil for almost two months. In late March 2020, the Correctional Service of Canada (CSC),
76 Canada's federal body responsible for incarcerated individuals serving sentences of at least two
77 years, had indicated that they had taken steps to prevent and were prepared to respond to
78 COVID-19 outbreaks inside its federal penitentiaries [9]. With this study, we aim to offer a

79 baseline situational assessment of COVID-19 testing and burden in Canadian federal
80 penitentiaries, from which future analyses can be based. This study aims to summarize and
81 compare the prevalence of testing, test positivity, COVID-19 prevalence, case fatality, and the
82 proportion of cases recovered within federal penitentiaries in Canada, by province and for
83 Canada overall, and to contrast these with rates in penitentiaries' respective provincial
84 jurisdictions.

85

86 **2. METHOD**

87

88 **Data and study population**

89

90 In an unprecedented act of transparency, CSC made COVID-19 testing and case numbers
91 publicly available for each federal penitentiary on their website. Data up until April 21, 2020,
92 were used [10]. Equivalent values for the Canadian population were extracted from the COVID-
93 19 Canada Outbreak Tracker Resource Hub [11]. For each indicator, described below, we
94 calculated prison-, sex-, and province-specific estimates. Prison population denominators were
95 approximated by the maximum prison capacity for each penitentiary [12]. For the general
96 population, denominators (i.e., total general population) were obtained from Statistics Canada
97 population estimates for the first quarter of 2020 [13].

98

99 Additionally, to provide a timeline for the number of tests and cases in prisons with possible
100 outbreaks (5 or more cases at the time of analysis), we used the Wayback Machine (archive.org)
101 to obtain all previous copies of CSC's COVID-19 reporting webpage [10]. The earliest version
102 of the CSC webpage was created on April 1, 2020, which provided cumulative data up until
103 March 30, 2020. There were eight additional updates, which reported on data from April 7, 8, 10,
104 12, 13, 15, 17, and 18, 2020. Cumulative data at each of these dates were merged with the data
105 from April 21, 2020, to create a time-series ranging from March 30 to April 21, 2020. For
106 calendar dates at which no CSC updates were made available, we filled in the information with
107 the data from the previous observation.

108

109 Given that several federal penitentiaries are in fact multiplex sites—either with distinct buildings
110 or units operating under different security levels (e.g. minimum, medium or maximum) or
111 offering distinct services (e.g. treatment facilities)—and that sub-population capacities were not
112 always available for each separate unit, we chose to group several multi-complex facilities in our
113 analyses. This was the case of Quebec’s Federal Training Center Multi-Level Unit and Minimum
114 security facility; British Columbia’s Pacific Institution, Pacific Institution Regional Treatment
115 Center and Pacific Institution Reception Center; Ontario’s Millhaven Institution, Millhaven
116 Regional Hospital and Millhaven Regional Treatment Center, as well as Collins Bay Minimum
117 Institution and Collins Bay Regional Treatment Center, and Joyceville Institution and Joyceville
118 Minimum Institution. With these groupings, we recorded 51 facilities. We were able to analyze
119 data from 50 of these facilities (98%) (all data in Supplementary File 1).

120

121 **Measures**

122

123 ***Total tests and cases***

124 The total number of tests performed was obtained directly from the CSC and the Canada
125 Outbreak Tracker Resource Hub websites. CSC reports on the number of “positive tests”. We
126 considered all “positive tests” as confirmed cases.

127

128 ***Tests per 1000 population***

129 Tests per 1000 population were estimated by dividing the total number of tests performed by the
130 total population in each facility, in the prisoner population of each province, and the general
131 population of each province, respectively, and multiplying the fraction by 1000.

132

133 ***Test-positive rate***

134 We estimated the proportion of tests that were positive by dividing the total number of positive
135 tests (confirmed cases) by the total number of tests, in each prison, provincial prison population,
136 and the provincial general population.

137

138 ***Tested COVID-19 prevalence***

139 We estimated the prevalence of COVID-19 as identified through tests in the penitentiary and
140 provincial populations by dividing the total number of positive tests (confirmed cases) by the
141 population of each facility, the total prison population by province, and the total provincial
142 population, respectively. This indicator can also be considered the cumulative incidence
143 proportion.

144

145 *Proportion recovered*

146 To offer a crude estimate of the evolution of the epidemics inside and outside of prisons, we
147 estimated the proportion of cases that had recovered. This was done by dividing the number of
148 cases who had recovered by the total number of positive tests (total confirmed cases).

149 Operational definitions of recovered cases vary across jurisdictions in Canada, and CSC does not
150 define their measure in their reporting. Recovered cases are those who either received
151 confirmatory negative test results or for whom 10 to 14 days have elapsed since the start of their
152 symptoms and they are symptom-free for at least 2 to 3 days [14, 15]. Therefore, we interpret
153 recovered case numbers with caution.

154

155 *Population categories in prisons with outbreaks: Susceptible, Infected, Recovered and Died*

156 An outbreak of COVID-19 within confined populations, such as long-term care homes, can be
157 declared after a single resident or staff member is confirmed positive [16]. Thus, we consider
158 prisons with one or more reported cases of COVID-19 among its prisoner population as those
159 experiencing outbreaks. To describe the evolution of testing and incidence in prisons with
160 outbreaks across our study period, we classified each prison's population into four categories, for
161 each calendar day of the study period. We estimated the number of prisoners who were
162 "susceptible" to infection by subtracting the total number of confirmed active, recovered, and
163 deceased cases from the maximum population capacity of each prison. Prisoners considered
164 "infected" were those with positive tests who had yet to recover or die. Prisoners declared to be
165 "recovered" were assumed to no longer present active infections or be susceptible to infection.
166 Lastly, the total number of prisoners who had "died" were those whose death was declared to
167 result from COVID-19 complications.

168

169 **3. RESULTS**

170

171 **3.1 Testing inside versus outside federal prisons**

172

173 An analysis of testing within all federal penitentiaries illustrates both the heterogeneity of
174 COVID-19 testing within prisons in Canada and a low if not a complete absence of testing in
175 many facilities (Figure 1). Twelve of the 50 facilities studied—nearly one in five (24%)—had
176 recorded a complete absence of testing (indicated by hollow bars in Figure 1). Approximately
177 72% of all facilities (36/50) recorded fewer tests than the Canadian general population average of
178 16 tests per 1000 population. Facilities with higher levels of testing per 1000 population, tended
179 to be those that had already reported a higher COVID-19 prevalence (Figure 1).

180

181 On average across provinces, New Brunswick, Nova Scotia, Alberta, and Saskatchewan have
182 been testing less inside prisons than in the general population (Figure 2). The opposite is true for
183 Quebec, Ontario, and British Columbia, which were likely responsible for driving the average of
184 34 tests per 1000 population observed for the prison population, overall.

185

186 **3.2 Prevalence of COVID-19 inside versus outside federal prisons**

187

188 The high positive test rates and estimated prevalence of COVID-19 in prisons in Quebec and
189 British Columbia point to emerging outbreaks in these provinces (Figure 2). Prevalence was 10
190 times higher in Quebec, 6 times higher in British Columbia, and 2 times higher in Ontario within
191 federal prisons compared to the general population of each province (Figure 2).

192

193 Many of the hardest-hit penitentiaries are near major city centers. In Quebec, this was the
194 Federal Training Center complex in Laval, just north of Montreal (51 cases, 7% COVID-19
195 prevalence) and, Joliette Institution for Women in Joliette, a 1-hour drive away from Montreal
196 (51 cases, 39% prevalence). However, Port Cartier Institution in Côte Nord (a relatively remote
197 region of the province) also reported 15 cases (Figure 1). In British Columbia, most affected was
198 the Mission Medium Security Institution, a 1-hour drive away from Vancouver (64 cases, 30%
199 prevalence) (Figure 1). Ontario's Grand Valley Institution for Women, located in Kitchener (1-
200 hour drive away from Toronto) also experienced a smaller outbreak of 8 cases (6% prevalence).

201

202

Figure 1: Test-positive proportion, case prevalence, and testing per 1000 population for all federal penitentiaries.

203

204 Figure 2: Testing per 1000 population, test-positive rate, and prevalence of positive tests, for federal prison and general populations, by province and in Canada
 205 overall

206

207 In the five institutions with one or more cases, we found that testing was largely reactive, with
208 the onset of concentrated testing efforts occurring after COVID-19 outbreaks had already
209 established. An exception to this observation was Quebec’s Federal Training Center, which was
210 the only facility recording negative tests before the observations of positive tests (Figure 3).
211 Further, though institutions all recorded a gradual increase in the number of tests performed over
212 time, the high proportion of positive tests throughout the study period suggests that these prisons
213 likely did not implement more intensive, wide-spread testing throughout the prison populations
214 once a case was observed. An exception to this, however, was Ontario’s Grand Valley Women’s
215 Institution, which recorded a significant jump in testing once the first cases were confirmed, with
216 a majority of tests returning negative since April 7, 2020.

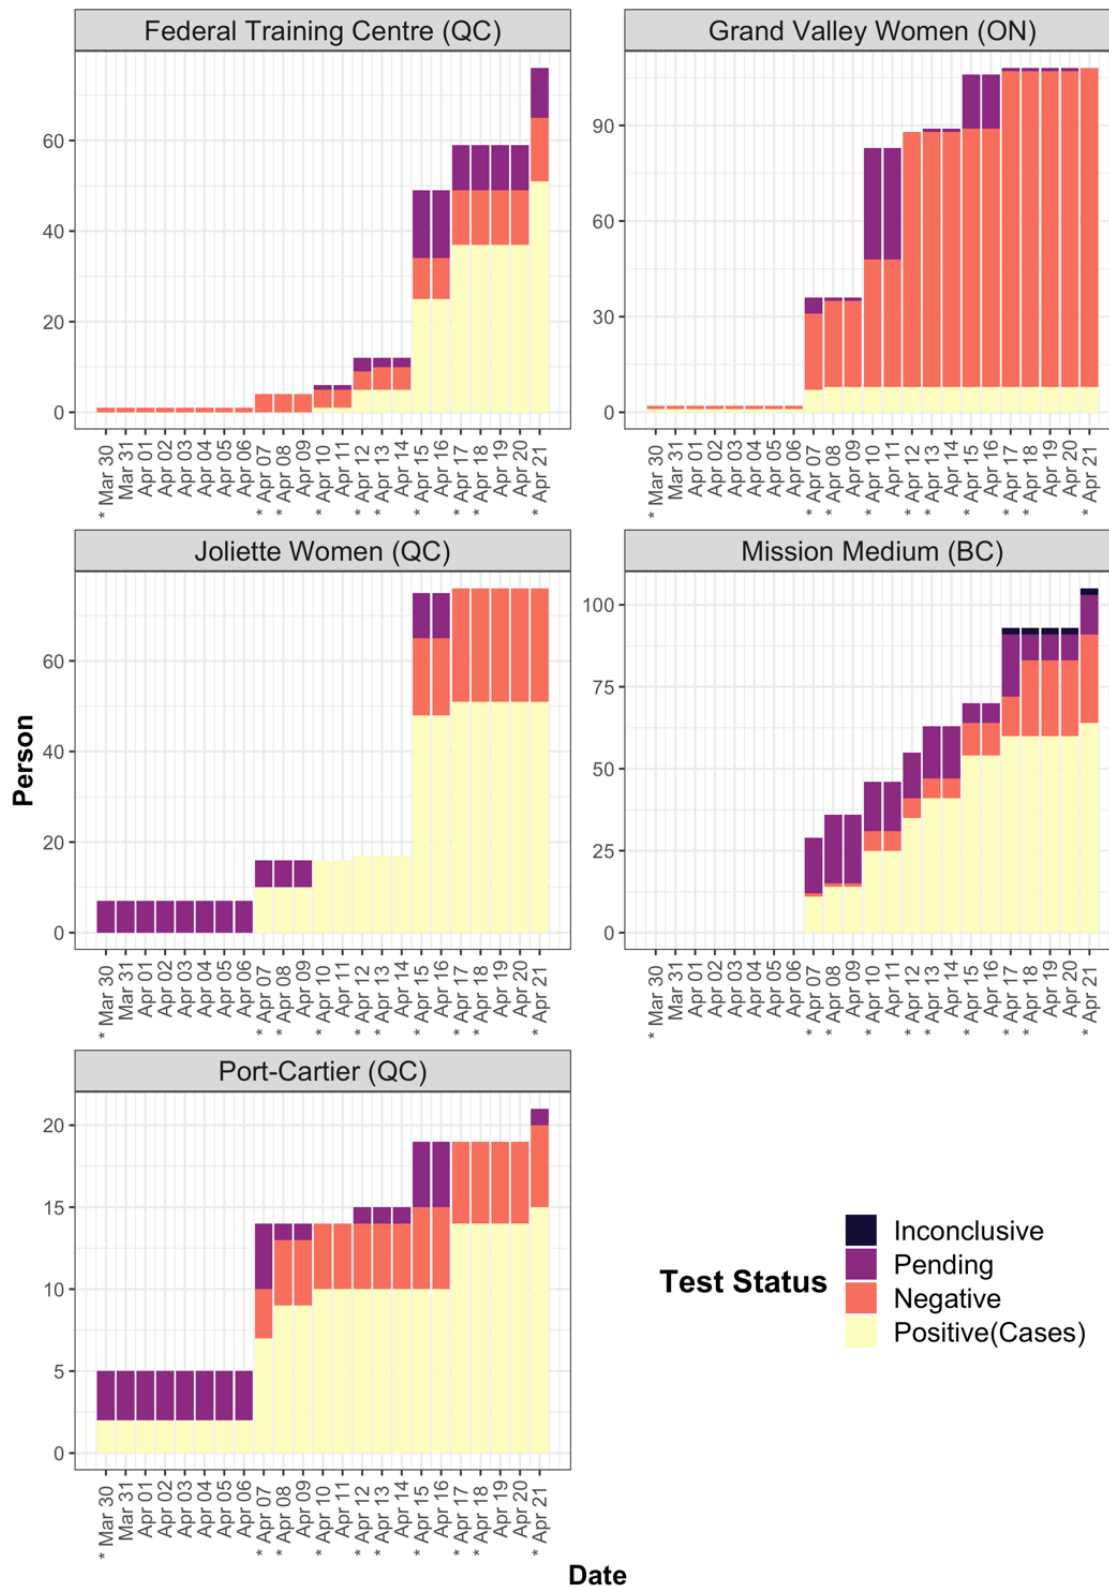

217

218 **3.3 Proportion of cases recovered and fatality inside versus outside prisons**

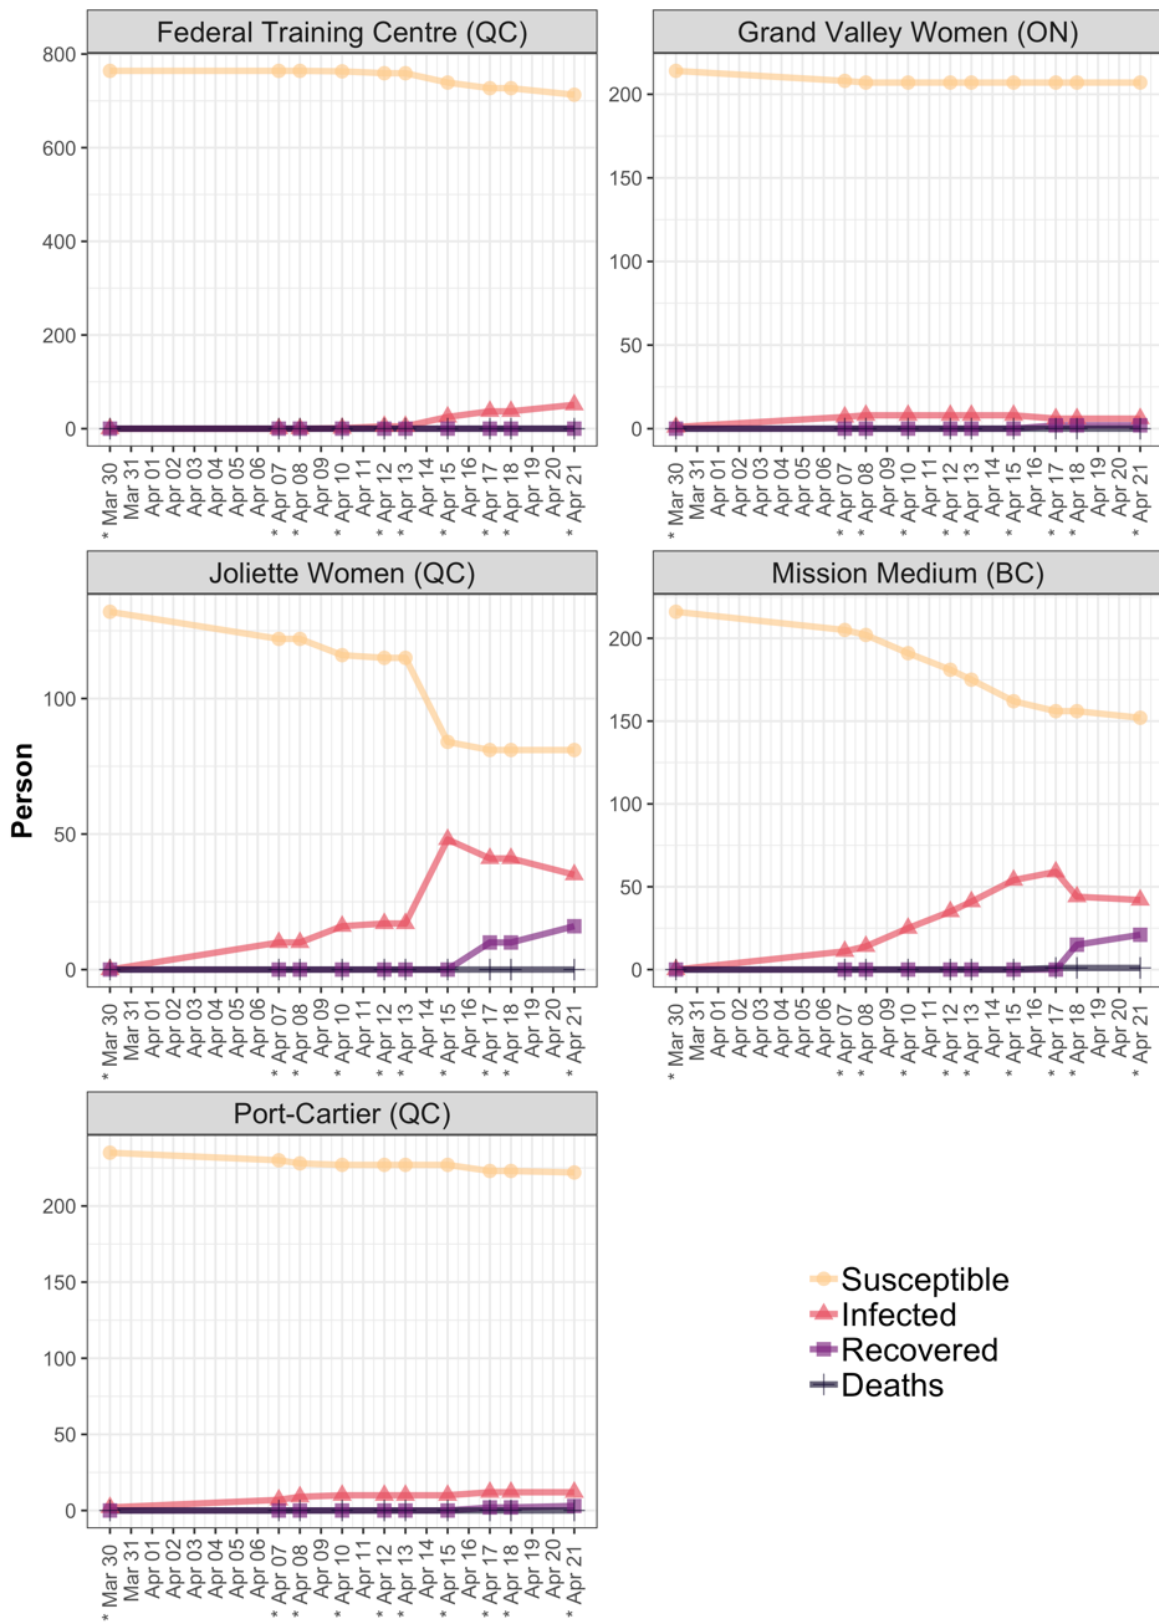

219

220 The proportion of cases that had recovered inside federal penitentiaries ranged from 0% to 33%
221 (Figure 1). The Susceptible, Infected, and Recovered plots (Figure 4) illustrate what proportion
222 of prisoners each prison with one or more cases have become infected and have recovered or
223 died throughout the study period. Of the five prisons with outbreaks, Quebec’s Joliette Women’s
224 Institution and British Columbia’s Mission Medium Institution have the seen largest proportion
225 of their population become infected and subsequently recover. Smaller proportions of cases have
226 recovered in Quebec’s Federal Training Centre and Port-Cartier and Ontario’s Grand Valley
227 Women’s Institution, and plot results suggest that a large proportion of prisoners remain
228 susceptible in these institutions (Figure 4).

229

230
 231 Figure 3: Testing patterns and outcomes between March 30 and April 21, 2020, in five penitentiaries with one or
 232 more recorded COVID-19 cases. * Indicated date at which data was reported by Correctional Services Canada.

233

234 Figure 4: Number of susceptible, infected, recovered cases and deaths between March 30 and April 21, 2020, in

235 penitentiaries with one or more recorded COVID-19 cases. * Indicates date at which data was reported by CSC.

236 In contrast to cases in the general population, a smaller proportion of cases in federal
237 penitentiaries in Quebec, Ontario, and British Columbia had recovered (Figure 2). In both
238 Ontario and British Columbia, the proportion of individuals who had recovered within prisons
239 was half that of the proportion of cases recovered in the community. With the available evidence,
240 it is difficult to know precisely what may be driving these differences in percent recovered inside
241 versus outside of prisons. One explanation is that outbreaks inside prisons may have started more
242 recently than those within the general public. Another possibility is that health and sanitary
243 conditions within prisons may lead to lags in recovery. Further, this cross-sectional summary of
244 differences must be interpreted with caution, since the proportion of cases that are recovered will
245 vary according to the number of new incident cases observed in both settings.

246
247 At the time of data collection, one of the 189 laboratory-confirmed cases across all federal
248 penitentiaries had died (0.5%), a 67% higher proportion than that observed in the general
249 population, (0.3%, 1,966 of 614,340 cases). Case fatality estimates should be interpreted with
250 caution, however, given the likely underestimation of the true number of cases (denominator
251 value) in both settings.

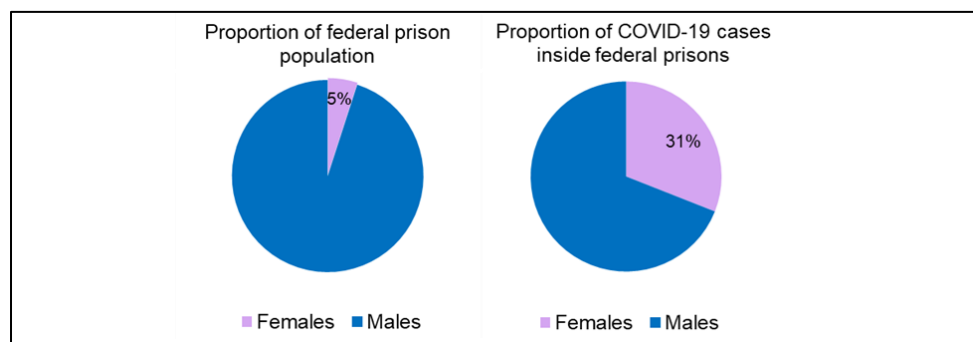

252

253 3.4 Testing, prevalence and proportion recovered by sex

254

255 Among the 50 facilities included in these analyses, six are penitentiaries for women (Nova
256 Institution for Women in Nova Scotia, Joliette Institution in Quebec, Grand Valley Institution for
257 Women in Ontario, Edmonton Institution for Women in Alberta, Fraser Valley Institution in
258 British Columbia, and Okimaw Ohci Healing Lodge in Saskatchewan). Together they hold up to
259 785 women (5% of the total capacity of 16,401 federal prisoners in Canada).

260

261

262 Figure 5: Distribution of women among federal prisons and prison COVID-19 cases (Canada, April 21, 2020).

263 At the time of data collection, there were 59 cases of COVID-19 in women’s penitentiaries.
264 These represented 31% of all cases in federal penitentiaries (N=189) (Figure 5), suggesting that
265 women, and women’s penitentiaries, are over-represented among COVID-19 cases inside federal
266 prisons. COVID-19 prevalence was 8 times higher among women’s prisons (8% prevalence)
267 than prisons for men (1% prevalence) and 80 times higher than in the general Canadian
268 population (0.1%).

269

270 **4. DISCUSSION**

271

272 *Key findings*

273

274 The data suggest that at least five federal penitentiaries, one in British Columbia, three in Quebec
275 and one in Ontario, are experiencing COVID-19 outbreaks. Each of these penitentiaries is
276 reporting high levels of testing, compared to provincial and national rates, and this testing
277 appears to be a reaction to the emergence of outbreaks that have already begun, rather than a
278 proactive prevention effort. Though at least thirteen (26%) of facilities appear to be experiencing
279 very low if any COVID-19 cases, these are also facilities that have reported low levels of testing
280 per 1000 population, so it is unclear whether the low case counts reflect true case prevalence. We
281 observed lower levels of testing than the Canadian general population average in 26
282 penitentiaries (72%) and a total absence of testing in 12 penitentiaries (24%). Our study also
283 suggests a smaller proportion of cases inside prisons have recovered compared to cases in the
284 general population. This may indicate that the spread of COVID-19 is lagging in penitentiaries,
285 and the worst is yet to come. It may also indicate that prisoners face suboptimal conditions for
286 recovery. We also found that at least three of the current penitentiary outbreaks are in proximity
287 to city centers (e.g. Montreal and Vancouver), and higher COVID-19 prevalence has been
288 observed in women’s (8% prevalence) compared to men’s prisons (1% prevalence), overall.

289

290 *Strengths and limitations*

291

292 The primary strength of this study is its use of the best available data on COVID-19 testing and
293 case incidence in Canadian Federal penitentiaries and the general Canadian population to give an

294 early situational report on testing and infection-related outcomes within these facilities. This
295 study is a baseline assessment from which future analyses using updated data can be based. A
296 limitation of this study is our use of the maximum potential capacity of each penitentiary as the
297 population denominator for rate calculations, rather than the ‘true’ population at the time of data
298 collection. We expect that these denominators are likely too large, given that prisons may not be
299 at their full capacity and pressures to release non-violent offenders to reduce the number of
300 susceptible individuals within prisons [17]. This may have led to the under-estimation of testing
301 and infection prevalence estimates. Further, this study was not able to also count the number of
302 tests and cases identified within custodial and health staff within these same penitentiaries, which
303 is an important contributing factor to disease transmission. While other deaths in federal
304 penitentiaries were recorded by CSC during the study period (e.g. [18]), only one case was
305 reported as COVID-19 related. It is unclear whether other deaths occurring within CSC facilities
306 have or will be tested for COVID-19 post-mortem. Lastly, these findings may not be
307 generalizable to provincial, remand, or immigration detention facilities, which may see far more
308 movement in and out given the shorter duration of sentences.

309

310 *Implications*

311

312 These early findings have several implications for public health and emergency outbreak
313 response inside federal penitentiaries. The observation that at least five Canadian penitentiaries
314 are experiencing outbreaks highlights the importance that all penitentiary populations and
315 custodial and health care staff uphold rigorous prevention control practices (and be given the
316 resources to do so), including regular hand hygiene and cleaning practices, the use of personal
317 protection equipment, and physical distancing measures [19]. Scholars and legal experts have
318 also emphasized the need to consider the release of prisoners to reduce the proportion of
319 susceptible individuals within prisons [20].

320

321 Our findings of sparse testing across several penitentiaries in Canada suggests that a more
322 proactive testing approach may be needed to help curb potential future outbreaks. This is
323 especially the case given studies suggesting that up to 60% of COVID-19 cases may be
324 asymptomatic [21-23]. Testing based on symptom-presence alone may thus need to be

325 reconsidered within the confined spaces of prisons, as many cases may go undetected as long as
326 testing is not expanded.

327
328 Relevant testing strategies could include universal testing or, active, sentinel-based testing.
329 While universal testing [19] [24] is time and resource-intensive but is much more feasible within
330 small confined populations than in the general public. In the context of COVID-19, this strategy
331 has been used navy ships [21] and homeless shelters [25, 26] to identify all cases and adapt
332 outbreak control interventions accordingly. In Canadian penitentiaries, universal testing may be
333 most pertinent in prisons that have already reported confirmed cases. At the time of writing,
334 British Columbia's Mission Institution penitentiary — where one of the five outbreaks is
335 unfolding — had reported planning universal testing of all inmates and staff [27]. However, none
336 of the other institutions had indicated plans to use such an approach.

337
338 As an alternative to universal testing, active sentinel surveillance involves identifying a subset of
339 prisons in which regular testing for COVID-19 among prisoners and staff, regardless of symptom
340 presence, could be conducted. Test results would be used for monitoring in the months to come
341 until a vaccine or effective treatment is identified. This approach may be most relevant in
342 provinces with low numbers of new daily COVID-19 cases (e.g. currently New Brunswick, Nova
343 Scotia, Saskatchewan and Manitoba currently) or in later in the pandemic, when community
344 transmission subsides and testing all prisoners may be too costly and inefficient.

345
346 These types of proactive surveillance activities may be particularly important in the context of
347 alternative options to reduce the spread of COVID-19, such as long-term cell-based confinement
348 for the entire prison population. Confinement has been associated with severe mental health risk
349 [28]—particularly for Indigenous and racialized populations [6]—and has come under
350 considerable scrutiny in Canada in recent years [29].

351
352 Lastly, studies on the effectiveness of universal and sentinel-based testing strategies are
353 warranted, as are mathematical models that explore the epidemiologic consequence of
354 interventions (or lack thereof) within federal prisons on COVID-19 transmission, morbidity and
355 death, as has been done in other country settings [30].

356

357 **5. CONCLUSION**

358

359 Gaps in COVID-19 testing in several jurisdictions and recorded outbreaks in several
360 penitentiaries in Canada suggest that federal prisons represent an emerging battleground against
361 the COVID-19 pandemic. With an ageing population that is particularly at high risk due to the
362 prevalence of underlying chronic and infectious health conditions, prisoners represent a
363 potentially neglected segment of society that is at high risk of bearing a high burden of COVID-
364 19 related morbidity and mortality. As indigenous and racialized communities are over-
365 represented within the Canadian prison system, COVID-19 prevention inside penitentiaries
366 represents a pressing public health and health equity issue.
