The eigenvalues of the stability matrix come from the roots of the quadratic eq
 $\lambda^2 - Tr\lambda + \Delta =$

$$
\lambda^2 - Tr\lambda + \Delta = 0 \tag{8}
$$

 $\begin{array}{c} \n\text{F} \\
\text{F} \\
\$ The eigenvalues of the stability matrix come from the roots of the quadratic equation
 $\lambda^2 - Tr\lambda + \Delta = 0$ (8)

Tr is the trace of the stability matrix and Δ is the determinant. For instability we need $Tr > 1 + \Delta$

The trac $\lambda^2 - Tr\lambda + \Delta = 0$ (8)
Tr is the trace of the stability matrix and Δ is the determinant. For instability we need
The trace is
 $Tr = 2 + a[p - g + \eta(1 - p)]$ (9) $\lambda^2 - Tr\lambda + \Delta = 0$ (8)
Tr is the trace of the stability matrix and Δ is the determinant. For instab
The trace is
 $Tr = 2 + a[p - g + \eta(1 - p)]$ (9)
while the determinant works out to be Tr is the trace of the stability matrix and Δ is the determinant. For instability we need $Tr > 1 + \Delta$
The trace is
 $Tr = 2 + a[p - g + \eta(1 - p)]$ (9)
while the determinant works out to be
 $\Delta = 1 + a[p - g + \eta(1 - p)] - a^2 pg$ (10)

$$
Tr = 2 + a[p - g + \eta(1 - p)]
$$
 (9)

while the de

$$
Tr = 2 + a[p - g + \eta(1 - p)]
$$
 (9)
while the determinant works out to be

$$
\Delta = 1 + a[p - g + \eta(1 - p)] - a^2 pg
$$
 (10)

So, the origin is destabilized for $a^2pg > 0$ which is always true.

Linearizing around the fixed point (1,0).

$$
\delta y_{n+1} = (1 - ap)\delta y_n - a[\beta + p(1 + \alpha)]\delta z_n \qquad \text{(11a)}
$$

$$
\delta z_{n+1} = -a(1 - p)\delta y_n + [1 + a(\beta - g) - a(1 + \alpha) + ap(1 + \alpha)]\delta z_n \qquad \text{(11b)}
$$

The requirement for the stability of this fixed point, as calculated by a procedure identical to above, is p *g* $>$ β . The fact that this fixed point has a stability zone (see Fig 1) shows its importance in the problem and is really the primary feature of this work. The stability zone makes good sense as it requires the probability of producing asymptomatics in an interaction to be greater than a critical value. It is also favoured if the interaction producing the symptomatic from asymptomatics is small. What this fixed point physically signifies is that the number of asymptomatic carriers is greater than the symptomatic ones by order of magnitude if this fixed point is stable. One can argue that we did not get a finite ratio, we have got something infinitely large and hence is unphysical. As soon as the effect of contact tracing is included this infinite ratio becomes large but finite. Even when this fixed point is unstable it can fashion the course of the dynamics.

Fig 1: The stability and instability zones of fixed point (1,0)

The important parameters, from Eq.(6) ought to be p,g and a. Moreover, the parameter 'a' control sall the other interaction parameters. But actually parameter 'a' was the interaction term between susceptible and asymptomatic patients. This shows the importance to include asymptomatics for coronavirus dynamics. We will keep the parameters η and α fixed at unity. We will consider two cases:

i) y_0 and z_0 comparable.

ii) y_0 significantly greater than z_0 .

In Case1, we choose parameters p=0.5, g=0.5 , β = 1 and a=0.5 which leads to $y_0 = 0.25$ from Eq.(6) and $z_0 = 0.25$ from Eq. (7). We show z_n vs n in Fig 2 as Case 1.

In Case 2, we choose p=0.8, $g = 0.75$, $\beta = 1$ and a=0.5 which leads to $y_0 = 0.6$ from Eq.(6) and $z_0 = 0.132$ from Eq.(7). The trajectory z_n is shown as Case 2 in Fig2.

Fig 2: Case 1 and Case 2 are shown above. The parameters for Case 1 p=0.5, g=0.5,

and a=0.5. The parameters for Case 2 p=0.8, g=0.75,

Where z^* is the saturated fixed point for asymptomatics. $Z^*=0.25$ in case 1 and $Z^*=0.132$ in case 2.

The primary difference between the two cases is in the rate at which the saturation is approached. The influence of large number of asymptomatic carriers makes the saturation of the symptomatic infected much slower than in Case 1. This dynamics is likely to show a long-time tail.

We now want to show that the map considered here is not totally irrelevant in practice. To do so, we consider the instance of Austria where an early lockdown was declared by the government and for the most part the growth and saturation of the disease occurred under the same conditions. For a wide variety of choice of parameters similar to the Case1 above, we can get a reasonable description of the time development of the variable 'z'. This is shown in Fig 3, where we also show the best fit curve to the data.

Fig 3: In above graph "Real Z/Z* Austria" represent the actual Z/Z* of Austria from 13 March to 12 April. The days are scaled accordingly. Case 3 is the same as Case 1 only the interaction parameter a=0.65. Before 8^{th} scaled day case 3 overlaps with the actual data of Z/Z^* and after 8^{th} day Case 1 overlaps. This clearly shows that the interaction parameter'a' has reduced from a=0.65 to a=0.5 due to lockdown and governmental policies.

 A far more complicated is the situation in South Korea where in the very early stage, the Shincheonji gathering produced an unusually fast exponential decay which sent the new cases up to 5000 very soon (about 20 days). Government intervention then slowed the growth and eventually it saturated at a value slightly above 10000 in the next 40 days. Hence in terms of the normalized z_n / z_0 , the half way mark is reached incredibly fast and then the rest proceeds like Austria. Consequently, to understand this data, we need to have an "extreme" set of parameters the first 20 days and then switch to Austria-like parameters in the next 40 days. This is what we show in Fig 4.

 $\frac{1}{2}$ above graph "Real Z/Z" South Korea" represents the actual value of Z/Z^* of South Korea from 12 Feb to 14 April. Days are scaled accordingly. Before 4th scaled day, parameters are difficult to predict due rapid
Charles and results are seen to be a control of the state o fluctuations of parameters because of the Shincheonji gathering but it can be approximated to p=0.01, a=0.9,
g=0.2, 0.15th scaled day onwards probability of getting asymptomatics increased p=0.5 . On 5th scaled day onwards probability of getting asymptomatics increased p=0.5 because of lockdown and government policies. On 6th scaled day interaction parameter a decrease from 'a'=0.9 to a=0.8. On 7^{th} scaled day 'a'=0.7. Finally, on 8^{th} scaled day onwards interaction parameter 'a' decreases to a≈0.6 and remains constant afterwards.

3. Modification to include contact tracing:

The way things work in reality actually changes the fixed point (1,0) to something where the ratio of asymptomatics to symptomatic is large but finite. This is because while members of the set Y are generally not quarantined- an exception is when they are tested due to contact tracing. This implies that in Eq.(4) there will be an additional term which we call $-a\mu y_n$ and an identical term in Eq.(3) with the opposite sign keeping the conservation law intact. This modification changes Eq.(4) and Eq.(5) to

$$
y_{n+1} = y_n + a[p(y_n + \eta z_n)(1 - y_n - (1 + \alpha)z_n) - \beta y_n z_n - \mu y_n]
$$
(12)

$$
z_{n+1} = z_n + a\{(1-p)(y_n + \eta z_n)[1 - y_n + (1+\alpha)z_n] + \beta y_n z_n - g z_n\}
$$
(13)

The correction term μ_{y_n} is small as the coefficient is small- contact tracing contribution is a second order effect. As is obvious the fixed point (0,0) is unchanged but the fixed point (1,0) will be shifted by a term of $O(\mu)$ at the lowest order. We write

$$
y_0 = 1 - c_1 \mu \tag{14a}
$$

$$
z_0 = c_2 \mu \tag{14b}
$$

 $y_0 = 1 - c_1 \mu$ (14a)
 $z_0 = c_2 \mu$ (14b)

where $c_{1,2}$ are positive coefficients of order unity. From the fixed-point condition

(13), we obtain (we work with $\alpha = 1$ to reduce the number of coefficients)
 $p(y_0 + \eta z_0)(1$ $z_0 = c_2 \mu$ (14b)
where $c_{1,2}$ are positive coefficients of order unity. From the fixed-point condition
(13), we obtain (we work with $\alpha = 1$ to reduce the number of coefficients)
 $p(y_0 + \eta z_0)(1 - y_0 - 2z_0) = y_0(\beta z_0 + \mu)$ where $c_{1,2}$ are positive coefficients of order unity. From the fixed-point conditions for Eqs (12) and

(13), we obtain (we work with $\alpha = 1$ to reduce the number of coefficients)
 $p(y_0 + \eta z_0)(1 - y_0 - 2z_0) = y_0(\beta z_0 + \mu)$

$$
p(y_0 + \eta z_0)(1 - y_0 - 2z_0) = y_0(\beta z_0 + \mu)
$$
 (15a)

(13), we obtain (we work with
$$
\alpha = 1
$$
 to reduce the number of coefficients)

$$
O(\mu)
$$
 we can use just the first term of the

Since the Rhs of Eq.(16) is
obtain $z_0 = \frac{\mu(1-p)y_0}{pg - \beta y_0}$
Since the Rhs of Eq.(16) is already $O(\mu)$, we can us
obtain
 $z_0 = c_2 \mu = \mu \frac{1-p}{pg - \beta} +$ Since the Rhs of Eq.(16) is already $O(\mu)$, we can use just the first term of the Rhs of Eq.(14a) to

obtain
 $z_0 = c_2 \mu = \mu \frac{1 - p}{pg - \beta} + O(\mu^2)$ (17)

We need $pg > \beta$ for the sign to be right. To find the exact equation sat

$$
pg - \beta y_0
$$

lready $O(\mu)$, we can use just the first term of

$$
z_0 = c_2 \mu = \mu \frac{1 - p}{pg - \beta} + O(\mu^2)
$$
 (17)

We nee
insert $z_0 = c_2 \mu = \mu \frac{1-p}{pg - \beta} + O(\mu^2)$ (17)

We need $pg > \beta$ for the sign to be right. To find the exact equation satis

insert z_0 as given by Eq. (16) into Eq.(15a) and obtain for the non-zero fixe
 $p[y_0(pg - \beta y_0) + \mu \eta y_0(1-p$ We need $pg > \beta$ for the sign to be right. To find the exact equation satisfied by y_0 , we need to insert z_0 as given by Eq. (16) into Eq.(15a) and obtain for the non-zero fixed point values,
 $p[y_0(pg - \beta y_0) + \mu \eta y_0(1$ insert z_0 as given by Eq. (16) into Eq.(15a) and obtain for the non-zero fixed point values,
 $p[y_0(pg - \beta y_0) + \mu \eta y_0(1-p)][(1 - y_0)(pg - \beta y_0) - 2\mu(1 - p)y_0] = \mu (pg - \beta y_0)[pg - \beta y_0 + \beta y_0(1)]$

In the case where $\mu = 0$, we correctly

$$
p[y_0(pg - \beta y_0) + \mu \eta y_0(1 - p)][(1 - y_0)(pg - \beta y_0) - 2\mu(1 - p)y_0] = \mu (pg - \beta y_0)[pg - \beta y_0 + \beta y_0(1 - p)] \quad (18)
$$

In the case where $\mu = 0$, we correctly obtain

$$
y_0 (pg - \beta y_0)^2 (1 - y_0) = 0 \quad (19)
$$

The correction to $y_0 = 1$ to the lowest order is obtained by inserting the form of Eq. (14a) in Eq.

$$
y_0 (pg - \beta y_0)^2 (1 - y_0) = 0 \quad (19)
$$

In the case where $\mu = 0$, we correctly obtain
 y_0 ($pg - \beta y$

The correction to $y_0 = 1$ to the lowest order i

(18) to arrive at $y_0 (p_8 - p y_0) (1 - y_0) = 0$ (13)
The correction to $y_0 = 1$ to the lowest order is obtained by inserting
(18) to arrive at
 $c_1 = \frac{2(1-p) + g - \beta}{pg - \beta}$ The correction to $y_0 = 1$ to the lowest order is obtained by inserting the form of Eq. (14a) in Eq.

(18) to arrive at
 $c_1 = \frac{2(1-p)+g-\beta}{pg-\beta}$ (20)

We thus see that including the effect of contact tracing leads to a fin

$$
c_1 = \frac{2(1-p) + g - \beta}{pg - \beta} \tag{20}
$$

(18) to arrive at
 $c_1 = \frac{2(1-p) + g - \beta}{pg - \beta}$ (20)

We thus see that including the effect of contact tracing leads to a final state where asymptomatics

can be much larger than those with symptoms and this state exists and $v_1 = \frac{p_g - \beta}{p_g - \beta}$ (20)
We thus see that including the effect of contact tracing leads to a final state v
can be much larger than those with symptoms and this state exists and is sta
shown in Fig (1). Hence in reality, The must see that including the strict of contact tracing state of contact tracing incomponent can be much larger than those with symptoms and this state exists and is stable for the region shown in Fig (1). Hence in reali can be much larger than the existing properties and that the region shown in Fig (1). Hence in reality, the fixed point (1,0) is a limiting case of a more realistic fixed where the asymptomatic fraction is much greater tha where the asymptomatic fraction is much greater than the symptomatic fraction with both numbers' finite. The other positive valued fixed point discussed in Eqs (6) and (7) is also slightly shifted.

Similar both numbers of the symptom of $\frac{1}{2}$ and (7) is also slightly shifted. finite. The other positive value $\frac{1}{2}$ (e) and (7) is also slightly shifted.

3. Modification to include Latency:

among the contributions to y_{n+1} and z_{n+1} , apart from interactions of the variety $x_n z_n$ there could
be interactions with the z variety of the days n-1, n-2 and probably n-3. These would be interactions
of the set of the set X with some fraction of the numbers z_{n-1}, z_{n-2} and z_{n-3} . These terms which are of the
form $x_n z_{n-i}$ (i=1,2 and perhaps 3) can be approximated by one representative term $x_n z_{n-1}$ with an
effective coe form $x_n z_{n-i}$ (i=1,2 and perhaps 3) can be approximated by one representative term $x_n z_{n-1}$ with an effective coefficient in a minimal model. An identical argument holds for the generation of z_{n+1} from interaction effective coefficient in a minimal model. An identical argument holds for the generation of z_{n+1} from interactions between the set Y and the set Z. Consequently, the structure of Eqs (4) and (5) become [we use the par

become [we use the parameters
$$
\eta = 1, \alpha = 1
$$
]
\n
$$
y_{n+1} = y_n + ap(y_n + z_n + \varepsilon z_{n-1})[1 - y_n - 2z_n] - ay_n[\beta z_n + \chi z_{n-1}]
$$
 (21a)
\n
$$
z_{n+1} = z_n + a(1-p)[y_n + z_n + \varepsilon z_{n-1}][1 - y_n - 2z_n] + ay_n(\beta z_n + \chi z_{n-1}) - agz_n
$$
 (21b)

In the above ε, χ are two new parameters describing the strength of the latency effect. The fixed $y_{n+1} = y_n + ap(y_n + z_n + \varepsilon z_{n-1})[1 - y_n - 2z_n] - ay_n[\beta z_n + \chi z_{n-1}]$ (21a)
 $z_{n+1} = z_n + a(1-p)[y_n + z_n + \varepsilon z_{n-1}][1 - y_n - 2z_n] + ay_n(\beta z_n + \chi z_{n-1}) - agz_n$ (21b

In the above ε, χ are two new parameters describing the strength of the latency ef $z_{n+1} = z_n + a(1-p)[y_n + z_n + \mathcal{E}z_{n-1}][1 - y_n - 2z_n] + ay_n(\beta z_n + \chi z_{n-1}) - agz_n$ (21b)
In the above \mathcal{E}, χ are two new parameters describing the strength of the latency effect.
points $y_0 = z_0 = 0$ and $y_0 = 1, z_0 = 0$ are unchanged In the above ε , χ are two new parameters describing the strength of the latency effect. The fixed
points $y_0 = z_0 = 0$ and $y_0 = 1$, $z_0 = 0$ are unchanged while the non-trivial fixed point becomes
 $y_0 = pg / (\beta + \chi)$ wi points $y_0 = z_0 = 0$ and $y_0 = 1, z_0 = 0$ are unchanged while the non-trivial fixed point becomes $y_0 = pg / (\beta + \chi)$ with z_0 following from $[y_0 + z_0(1+\varepsilon)][1 - y_0 - 2z_0] = gz_0$. The linear stab of the fixed point is now obtained $y_0 = pg / (\beta + \chi)$ with z_0 following from $[y_0 + z_0(1+\mathcal{E})][1 - y_0 - 2z_0] = gz_0$. The linear stability
of the fixed point is now obtained from the roots of a cubic equation. To understand this in the
implest case, we need to l simplest case, we need to look at the (0,0) fixed point. The linear stability equation will now invertient in δz_{n-1} in each of Eqs (7a) and (7b) and these terms will be of $O(\mathcal{E})$ or $O(\chi)$. This meath that in addi a term in δz_{n-1} in each of Eqs (7a) and (7b) and these terms will be of $O(\mathcal{E})$ or $O(\chi)$. This means
that in addition to the stability matrix of Eqs. (7a) and (7b), we will have two more matrices one
involving the a term in δz_{n-1} in each of Eqs (7a) and (7b) and these terms will be of $O(\mathcal{E})$ or $O(\chi)$. This means
that in addition to the stability matrix of Eqs.(7a) and (7b), we will have two more matrices one
involving the that in addition to the stability matrix of the second and third columns. The determined these matrices enter the stability analysis and are clearly of $O(\mathcal{E})$ or $O(\chi)$. Straightforward algebra leads to a cubic having in this dimension and the first and the first and the clearly of $O(\mathcal{E})$ or $O(\chi)$. Straightforward
algebra leads to a cubic having the form $\lambda^3 - \lambda^2 Tr + \lambda(\Delta + O(\mathcal{E}, \chi) + O(\mathcal{E}, \chi) = 0$ The additional
root that we get is algebra leads to a cubic having the form $\lambda^3 - \lambda^2 Tr + \lambda(\Delta + O(\varepsilon, \chi) + O(\varepsilon, \chi) = 0$ The additional
root that we get is clearly small and cannot cause instability. Hence, we need to find the first
correction to the root grea root that we get is clearly small and cannot cause instability. Hence, we need to find the first
correction to the root greater than unity and that correction is positive ensuring instability of (0,0).
To explore the role

corresponding to our Case 1 in Fig2 with three different values of $\mathcal E$ and χ , This is shown in Fig 5. To explore the role of latency on the evolution of z_n , we have solved Eqs(21a) and (21b) corresponding to our Case 1 in Fig2 with three different values of $\mathcal E$ and χ , This is shown
corresponding to our Case 1 in F corresponding to our Case 1 in Fig2 with three different values of $\bm{\mathcal{E}}$ and $\bm{\mathcal{X}}$, This is shown in Fig 5.
 $\bm{\mathcal{E}}$

4. Conclusion

We have written down a Henon map for the transmission dynamics of COVID-19 which includes its two basic features- the existence of asymptomatic transmitters and a possible latency period for the symptomatics. The existence of an unexpected fixed point with a large ratio of asymptomatic to symptomatic influences the transmission dynamics strongly. In simple enough situations, the map is capable of producing a reasonable account of the observed dynamics.
