## **Abstract**

### Introduction

The novel corona virus (COVID19) can result in several neurological complications. Guillain-Barré Syndrome (GBS) is one of them and has been reported from different parts of the world in this pandemic. It is an acute post infectious polyneuropathy. The review aims to summarize the demographic features, clinical presentation, diagnostics workup, and management strategies of COVID-19 associated GBS reported in literature.

### Material and method

We searched Medline, PubMed Central, SCOPUS and Google Scholar using pre-defined keywords, with no time limits and in English language only. We aimed to include all kind of manuscripts. Last search was done on 18<sup>th</sup> May 2020. Demographics, clinical features, diagnostic workup, management, and outcomes were documented in the data sheet.

### Results

We identified 24 cases of COVID-19 associated GBS. Most of the cases were reported from Italy followed by USA. Majority were males (18 /24) The age ranged from 23 -84 years. The clinical presentation was typical sensory-motor GBS in most. Nine patients had facial palsy of which five had bilateral involvement. Two patients had bilateral abducent nerve palsy while two presented as paraparetic GBS variant with autonomic dysfunction. Electrodiagnostics was performed in 17 patients only and 12 had typical features of acute inflammatory demyelinating polyneuropathy. .

Intravenous immunoglobulins were the preferred mode of treatment in most of the patient. There was one death, and most were discharged to rehabilitation or home.

### Conclusion

GBS is a frequent neurological complication associated with COVID-19. There is no clear causative relationship between GBS, and COVID-19 at present and more data are needed to establish the casualty. However, most cases have a post-infectious onset with male preponderance. Most of the cases have a typical presentation but some may present in an atypical way. Prognosis is generally good.

**Keywords:** Neurology, Clinical features, Coronavirus, GBS, Polyneuropathy, Paraparesis, Rehabilitation

## **Introduction**

The novel coronavirus (COVID19) infection originated from Huanan seafood market in Wuhan city China in December 2019. It rapidly spread to more than 200 countries of the world with 7 million confirmed cases and more than 400,000 fatalities as of 10<sup>st</sup> June 2020.<sup>1</sup> COVID-19 primarily affects the respiratory tract and the lungs. However, involvement of cardiovascular, renal system and neurological system has also been reported. The reported neurological manifestations and complications of COVID-19 include anosmia, headaches, dizziness, delirium, stroke, epilepsy, encephalitis, encephalopathy, myalgias and Guillain-Barr é syndrome (GBS) <sup>2,3,4</sup> At present, there are no reviews, full length research article or reports discussing a specific neurological complications in detail.

The objective of this review is to summarize the important demographic features, clinical presentation, diagnostics, and management strategies of COVID-19 associated GBS reported in literature so far. We aim to inform the readers about this important neurological manifestation of COVID-19 in order to formulate better diagnostic and management strategies.

## **Historical Perspectives on Guillain-Barr é syndrome**

The mysterious link between infections followed by paralysis has intrigued physicians for centuries.<sup>5</sup> Although this relationship was mentioned by the famous Muslim physician Avicenna centuries ago and many other authors published their cases too, but the detailed description of the disease, including nerve conduction studies and cerebrospinal fluid analysis with albuminocytological disproportions was first documented by three French physicians Georges Guillain, Jean Alexandre Barré, and André Strohl, who were working together at the Neurological Center of

the French 6th Army during first world war. They treated and published data on two soldiers, who developed typical features of GBS with complete recovery. The disease was named Guillain-Barr é syndrome after them. <sup>6</sup>

### **Pathophysiology and Clinical Features of Guillain-Barr é syndrome**

GBS is acute onset immune mediated disorder characterized by rapidly progressive limbs and bulbar weakness which can lead to respiratory failure. <sup>7</sup>

Many triggers for GBS have been identified including bacterial and viral infections, surgery, and pregnancy. The link of GBS with vaccination is controversial.

Respiratory and Gastrointestinal infections constitute two third of cases. The molecular mimicry between the cell membrane antigen of microbe and ganglioside component of nerve antigen misdirects the immune response. This immune response is humoral mediated and not T cell mediated. The prototype example is of Campylobacter Jejuni infection. The carbohydrate moiety of lipooligosacchrides of Campylobacter Jejuni is capable of inducing antibodies that cross react with glycans present on nerve gangliosides.<sup>8</sup> The exact trigger to mount this misdirected immune response is still not known. There is no specific genetic predisposition as only 1% of all campylobacter infections will result in GBS. GBS has also been reported after viral infections for example Cytomegalovirus, Ebstein-Barr virus, Influenza, Zika, and Chikungunya virus.<sup>12,8</sup>

The clinical hallmark is hyporeflexia or areflexia. The course of the disease is monophasic. Recommended treatment for GBS includes plasmapheresis (PLEX) and immunoglobulins (IVIG) infusion.<sup>9</sup> GBS was initially described only as a

demyelinating polyneuropathy. Typical features of demyelination on electrodiagnostic studies (EDX) include prolong distal latencies, reduction of conduction velocity, prolong F-waves, temporal dispersion, and conduction block. Clinically many different variants with distinct clinical and electrophysiological features have been reported in literature<sup>2, 10</sup>. These include, cranial, autonomic, ataxic, paraparetic and mixed variety. The GBS reported from North America and Europe is predominantly demyelinating type while in Asian countries the axonal type of GBS constitutes 30-50 % of the reported cases.<sup>11,12,13,14</sup> The mortality of GBS reported from European and North American studies ranges from 3-7%, and is mainly due to respiratory failure, deep vein thrombosis and autonomic dysfunction. The axonal variants of GBS mostly reported in the Chinese and Asians populations have a poor prognosis.<sup>15</sup> The poor prognosis is because peripheral nerve remyelination is a natural and active process. Whereas in case of axonal variant of GBS, once the axonal integrity is damaged, it does not regenerate actively and completely.<sup>2</sup>

## **Basic Virology of SARSCoV-2**

SARS-CoV-2 belongs to the broad family of Coronaviruses sub-family beta Coronaviruses<sup>16</sup>. These are enveloped, single-stranded RNA viruses with a diameter of approximately 60–140 nm. The viral envelope has four structural proteins known as S (spike), E (envelope), M (membrane), and N (nucleocapsid). It is the interaction with the spike protein and host cell receptor which is essential for virulence and infectivity.<sup>17</sup>

## **Neurological injury due to Coronavirus**

Coronaviruses are not primarily neurotropic viruses and their primary target is respiratory and cardiovascular systems. It is through the Angiotensin-converting enzyme 2 (ACE-2) receptors the virus is attached to host cells leading to internalization and subsequent viral replication. This receptor is also found in glial cells in the Central Nervous System (CNS) and spinal neurons. Very rarely the virus can invade peripheral nerves and lead to retrograde transfer via synapse mediated route to CNS. Another proposed route of entry is through the olfactory nerves.<sup>18,19</sup> Past experience with Severe Acute Respiratory Syndrome (SARS) and Middle East Respiratory syndrome (MERS) related cases has also provided insights into the neuro invasive potential of Coronaviruses.<sup>20,21</sup> As the number of COVID-19 cases with neurological manifestations and complications are being reported more frequently, there is growing evidence for neurotoxic potential of COVID-19. This neurotoxicity can occur as a result of direct or indirect insult by virus and may manifest in form of post-infectious complications like GBS. In this review we will focus only on the post infectious complication only.

## **Mechanism of GBS in coronavirus infection**

COVID-19 does not directly invade peripheral nerves , nerve roots, or anterior horn cells leading to inflammation and death of motor neurons as seen in polio virus or West Nile virus. Even the Cerebrospinal fluid (CSF) Polymerase chain reaction (PCR) for coronavirus in multiple reported cases of COVID-19 related GBS has been negative.<sup>22</sup> It is likely a post infectious or may be a para-infectious complication resulting from an aberrant immune response. During the inflammatory phase numerous mediators of inflammation are released from activated leukocytes including Interleukin-6 (IL-6) ,named as Cytokine storm. This can result in major organ damage, rapid deterioration of the patient and ultimately death.<sup>23</sup> However, due to lack of experimental data It is difficult to deduct if IL-6 is also responsible for the c is also causing neurological damage <sup>37</sup> After the acute phase of the infection, an immune response is generated by the host and may lead to a misdirected response against host epitopes. It can result in an autoimmune, response directed against peripheral nerves and nerve roots in susceptible individuals. This may be either demyelinating or axonal degeneration type. This results in a typical GBS like presentation in the peripheral nerves and spinal roots. However, due to lack of clear data, there is still not enough evidence available to conclude if antibodies to any specific ganglioside antigen are present in these cases or not.

## Literature Search strategy

We searched Medline, PubMed Central, SCOPUS and Google Scholar using keywords “ COVID-19”, “Coronavirus”, “ Coronavirus Infections“, “Coronaviridae”, “2019 nCoV “. “pandemic”, “SARS-COV-2”, “neurology”, “neurological”, “complications”, “manifestations” , “Guillain-Barr é syndrome” , “GBS”, “acute inflammatory demyelinating polyneuropathy”, “Demyelinating Polyradiculoneuropathy”, “polyneuropathy”, and “Miller Fisher syndrome”. Different combinations of Boolean logic (AND, OR and NOT) were used to identify relevant articles. Search was limited only to English language manuscripts with no time limit. It is important to note that new data is being shared regularly and so far, it consists mostly of pre-prints, letters to editor, single case reports, small case series, and part of an article describing clinical features of COVID-19. Most of the data on COVID-19 at present is published from countries most severely affected, including China, Italy, Spain, and USA. The last literature search was done on 18<sup>th</sup> May 2020. At that time there was no specific research article, systematic or narrative review describing COVID-19 associated GBS. However, we identified two systematic reviews protocols on this topic registered in the International prospective register of systematic reviews.<sup>24,25</sup>

Both authors independently performed the literature search and compared the results for any major discrepancies. The information was extracted on a pre-designed data sheet. The items of interest were the demographic data, presenting features, clinical examination, laboratory and radiological investigations, treatment protocol and outcomes. Due to the limited number of cases and nature of the review,

a quantitative analysis was not done, and we have only provided a qualitative review of the retrieved information.

## Results

### Characteristics of included studies

After removing the duplicates, non-English manuscripts, and unrelated articles, we identified 24 cases of GBS in COVID-19, published in the English biomedical literature till 18<sup>th</sup> May 2020. These were published as letter to editor, case reports or case series. The results are summarized in the Tables 1 and 2.

### Demographics

Most of the cases (8) were reported from Italy<sup>26,27,28,29</sup> followed by the USA (4 cases)<sup>30,31,32</sup> Iran (3 cases),<sup>33,34</sup> Spain (3 cases),<sup>35,36</sup> Germany (2 cases)<sup>37,38</sup> and one case each from China<sup>39</sup>, France<sup>40</sup>, Switzerland<sup>41</sup> and Morocco.<sup>42</sup> Majority of the patients were males (18 /75%). The age ranged from 23-84 years and mean age is 60 years.

### Clinical Features

Most of the patients (17/24) had typical presenting features of GBS with sensory paresthesia followed by ascending paralysis. Three patients had Miller Fisher variant presenting as ataxia, ophthalmoplegia and areflexia. Total of nine patient developed facial palsy out of which six had bilateral facial palsy. One case had only bilateral facial palsy without any peripheral manifestations and was labeled as facial diplegic variant of GBS. Two patients developed bilateral sixth nerve palsy. One patient among above who initially presented with bilateral facial and hypoglossal palsy and progressed to a locked in syndrome like condition. One case each from the US<sup>31</sup> and Switzerland<sup>41</sup> initially presented with paraparesis and bladder and bowel

dysfunction. Spinal cord imaging was normal in both these cases and these were labeled as paraparetic variant with autonomic dysfunction.

An important peripheral nervous manifestation i.e. hyposmia and hypogeusia was reported in Five patients. One of them had complete reversal of hyposmia at the time of discharge. The predominant clinical presentation in majority of the cases was post-infectious. However, in three cases the onset of symptoms suggested a para-infectious course of disease.

### **Laboratory and Radiological Investigations**

Nasopharyngeal swab samples of all cases were PCR positive for COVID-19, except one case. That patient repeatedly tested negative but, later his serology tested positive for COVID-19. CSF PCR for COVID-19 was tested in twelve patients and it was negative in all. Ganglioside antibody was tested in twelve cases. It was positive in two case only. One of them was the Miller Fisher Variant. CSF analysis performed in 20 cases. Four patients had a normal CSF analysis while in 16 cases it showed albuminocytological disproportion of GBS.

An important finding was that revealed COVID-19 associated lung changes on High-Resolution Chest Tomography (HRCT) chest in fourteen cases. X-ray chest was normal in six cases and revealed pneumonia in one case. Chest imaging was not reported in two cases. This can potentially guide the clinicians. During this pandemic, in a GBS patient HRCT chest should be ordered in case of any doubt to detect possible COVID-19 associated pneumonia as both can be contribute towards respiratory failure.

## **Electrodiagnostic Findings (EDX)**

Nerve conduction studies/ Electromyography (NCS/EMG) were performed in 17 cases. Out of these twelve cases had prolong distal latencies (DML) and absent F waves suggestive of a typical demyelinating polyneuropathy. Four cases had Acute Motor and Sensory Axonal Neuropathy (AMSAN) variant and one had Acute Motor Axonal Neuropathy (AMAN) variant of GBS. However, in the Italian case series, the author reported their NCS/EMG as a mixed picture whereas a prolong DML and absent F waves favors a demyelinating variant.<sup>28</sup>

## **Treatment**

Three cases were ambulatory with minimum motor deficit and were not offered any treatment for GBS. One of them was a Miller Fisher variant. Nineteen patients were given IVIG. Among these two cases had repeat sessions of IVIG and two cases had PLEX after IVIG due to initial inadequate response. Two case had PLEX sessions as primary treatment one among them had IVIG after PLEX also.

## **Outcomes and discharge status**

One case expired due to complications. Nine patients were either discharged to nursing homes or shifted to rehabilitation for exercise. Complete recovery was reported in eight patients. At the time of publication of cases, three patients were on mechanical ventilation, one was critically ill, and no improvement was reported in one case. Outcome and discharge status were not mentioned for three cases.

## Discussion

This review suggests that COVID-19 associated GBS has emerged as an important neurological manifestation and complication of this global pandemic. Although, a clear association of COVID-19 leading to triggering of GBS is lacking at present, past experience with Zika Virus associated GBS suggests a possibility of causality between GBS and COVID-19 infection.

The onset of GBS was post infectious in all the cases in this review, except three in which it was para infectious. A similar pattern has also been seen in Zika Virus infections. Therefore, the treating physician should have a high index of suspicion in managing such cases. The patient might be in the infective stage of COVID-19 and proper barrier precautions will be necessary for the safety of hospital staff. Lung changes due to COVID-19 infection were seen in a large number of patients in this review (15/24). Fourteen had a positive HRCT and one had pneumonia on X ray chest. All of these cases had a positive Nasopharyngeal PCR. Therefore, it is important to consider that during the current pandemic respiratory compromise in GBS may not be entirely due to neuromuscular failure but may also be due to COVID-19 pneumonia. At the same time if the patient with COVID-19 is having deterioration of respiratory function or is difficult to wean from ventilator GBS should also be considered as one of the possible reasons.

This review suggests that in COVID-19 associated GBS, AIDP variant is more common followed by AMAN and AMSAN variants. However, Umapathi has recently suggested that Covid-19 GBS might be axonal due to paranodal pathologies and follow up EDX might help in reaching to a conclusion.<sup>43</sup> Three patients presented

with Miller Fisher syndrome variant which is a large number considering the very low incidence of Miller Fisher syndrome variant of GBS in general population.

The experience with Zika virus related GBS suggests that the patient present with typical symptoms including facial palsy on presentation, male predominance, and AIDP on EDX. A similar pattern was documented in this review. In a review from Puerto Rico facial weakness was seen in 62% cases of Zika Virus associated GBS as compared with 10% in non- Zika related GBS<sup>44</sup>. In this review 37.5 % of the cases had facial weakness with 5 having bilateral facial paralysis. The incidence of dysphagia in Zika Virus associated GBS has been reported to be 53.5% while it is very low in COVID-19 associated GBS (5/24 (20%).

Two patients had paraparesis at presentation followed by urinary retention and were later diagnoses as GBS. <sup>31,41</sup> This paraparetic pattern is seen more commonly in Zika Virus associated GBS cases. We do not know the exact mechanism of this phenomenon.

In 5 cases hyposmia and hypogeusia were either the presenting or co-existing features. <sup>29,35</sup> These were likely due to the COVID-19 infection and not because of GBS. This is an important finding and can be used as a clinical indicator of COVID-19 infections in suspected GBS cases.

Seropositivity of GBS for ganglioside antibody is reported to be around 30% with the cases of MFS having 95% GQ1b positivity. In this review only one case was positive GD 1b ganglioside antibody. However, this data is too small to make a conclusion

Most of the cases in this review were treated with 5 sessions of IVIG. In two cases, IVIG was repeated while in two cases PLEX was also done after giving IVIG. PLEX

has been used in two cases as initially and in one it was followed by IVIG due to inadequate response. One of the possible reasons for use of frequent use of IVIG in all these cases is that all of them were in high income countries with adequate resources and easy access to IVIG. We would like to suggest that in resource constrained areas and the developing world PLEX might prove to be equally beneficial as this is the preferred mode of treatment in cytokine storm syndrome due to COVID-19.

Most of the patients had a good outcome and were either discharged to home with complete recovery or were referred to rehabilitation for management of residual weakness and motor deficits. There was one death and four patients were reported to be on mechanical ventilation at the time of publication of the case reports.

However, due to the limited data, it is difficult to comment if COVID-19 associated GBS increases severity of illness, length of Intensive care Unit (ICU) admission and prolongs ventilatory support.

## **Comparison of MERS associated GBs Vs. and COVID-19 associated GBS**

The published data regarding neurological complication and manifestations associated with MERS is limited.<sup>45</sup>**Error! Bookmark not defined.**<sup>47</sup> In addition, MERS was an epidemic limited to one geographic area and GBS associated with MERS was rarely reported so it is not possible to make a detailed comparison between this and COVID-19 associated GBS due to paucity of data. There is one case report of a critical illness neuropathy due to prolong intensive care unit stay reported from Saudi Arabia.<sup>46</sup> Kim *et.al* identified only four cases from Korea during the 2015 our break of MERS, which presented with neurological features.<sup>45</sup> One was diagnosed as GBS Bickerstaff variant, second one as Intensive care unit associated neuropathy overlapping with GBS and last 2 were labeled as toxic neuropathy. All four had sensory features on presentation and one of them developed motor weakness and ophthalmoplegia. However, EDX evaluation and CSF examination was normal in all patients. Ganglioside antibody was also negative. Only one patient required mechanical ventilation and was given IVIG. The other three did not have motor weakness and were only kept under medical observation, provided supplemental oxygen and no specific treatment was offered. These epidemics limited to a specific geographic zone affecting only 2494 people (WHO estimates), unlike COVID-19 which is a global health care crisis affecting millions. However, the common feature among both is the craniobulbar involvement in both.<sup>47</sup> See Table 3

### **Comparison of Zika Virus associated GBS Vs. COVID-19 associated GBS**

The comparison of COVID-19 associated GBS with Zika Virus associated is presented in Table 3. In Zika Virus-GBS the median time from symptoms to disease onset was seven days consistent with para infectious GBS whereas in this review the median time was 11 days (3-28) days. In Zika Virus GBS the disease was more aggressive with frequent ICU admission and need for ventilatory support. Our data reports a similar pattern with a total of nine patients needing respiratory support. Seven were placed on mechanical ventilation and two were on noninvasive ventilation. On EDX evaluation demyelinating type is the most finding both with =Zika Virus and COVID-19 associated GBS. Cranial involvement is another feature common to both types of GBS.

## Limitations

Despite a rigorous search methodology for this review, we were not able to perform literature search all the major English bio-medical literature search databases due to lack of resources and access. There is a possibility that we might have missed some cases which we hope will be identified in the systematic reviews registered in the International prospective register of systematic reviews. The total number of confirmed cases of COVID-19 globally is now more than 7 million but we were able to document only 24 cases of GBS reported in the English biomedical literature so far. This is a very small number of cases to make a causal relationship or a definitive conclusion regarding COVID-19 associated GBS. Due to the wide spread of the disease and wide variations in the documentation and reporting of data from different parts of the world, there are chances that mild cases of GBS or cases with limited involvement might be missed or do not report to hospitals. Moreover, neurological services are not widely available in many developing countries and there is a possibility that some COVID-19 associated GBS cases remain undiagnosed due to lack of expertise in neurology. In addition, mortality in COVID-19 cases due to rapidly progressive respiratory failure is usually attributed to the COVID-19 itself. There is a possibility of co-existing GBS which may contribute to the worsening of the condition. We hope that as more data from different parts of the world is shared, things will become clearer in future and provide further insights into the COVID-19 associated GBS..

## **Conclusion**

The primary presentation of COVID-19 is respiratory but neurological manifestations and complications are increasingly being reported in the literature. GBS is one of the frequent neurological complication associated with COVID-19. There is no clear causative relationship between GBS, and COVID-19 at present and more data are needed to establish the casualty. However, from the available data we conclude that most of the cases present as a post-infectious disease with male preponderance. The EDX reveal a demyelinating type of polyneuropathy in most of the cases with few being AMAN and AMSAN variants. IVIG is the preferred mode of treatment and prognosis is generally good with most of the patients responding to treatment and rehabilitation plan. There is a need for large scale data collection on GBS and other related neurological manifestations and complications of COVID-19 to formulate better care plans in future.

**Table 1: Details of the Demographics and clinical features of COVID-19 related GBS**

	Country	Author	Age (Years)	Gender	Presenting symptoms	Clinical Examination	H/o Respiratory or GIT infection	Travel history
1.	China	Zhao	61	Female	Acute weakness both legs, Severe fatigue	Symmetrical weakness grade 4/5 on MRC Scale Areflexia After three days power 3/5 legs Sensations decreased to light touch in feet	Develop fever and cough on eight day of illness.	Travel to Wuhan City, China
2.	Iran	Sedaghat	65	Male	Started from lower limbs Five days upper limbs involved symmetrical ascending quadriparesis, Bilateral facial palsy	UL Muscle Power 2/5 proximal and 3/5 distal LL Muscle Power 1/5 proximal and 2/5 distal Areflexia Impaired vibration and proprioception distally (DM)	Cough, Fever, and dyspnea 02 weeks prior to admission	Not Reported
3.	France	Camdessa nche	65	Male	paresthesia hands and feet progressed to Quadriplegia in 3 days	2/5 in legs and arms proximally. 3/5 forearm and 4/5 hand Areflexia Absent vibrations Dysphagia present	Cough and fever 11 days before admission	No
4.	USA	Virani	54	Male	Numbness and weakness.	Power 4/5 LL initially	Fever at presentation.	No

					followed by Urinary retention and ascending paralysis	Progressed to 2/5 Areflexia	Cough for 10 days	
5.	Spain case 1	Gutiérrez	50	Male	Vertical diplopia, Gait instability, perioral paresthesia Headache	Ataxia and Areflexia Right INO, Right 3 <sup>rd</sup> nerve palsy No facial weakness Anosmia and ageusia	Five days back Fever, cough Malaise and backache	No
6.	Spain case 2	Gutiérrez	39	Male	Diplopia and ageusia	Bilateral abducent palsy Areflexia No ataxia and Gait instability	Fever and diarrhea 3 days before admission. No respiratory symptoms No respiratory symptoms	No
7.	Italy	Toscano,	77	Female	Paresthesia in lower limbs and hands, Acroparesthesia and hypogeusia	Flaccid quadriplegia Areflexia Later on dysphagia and respiratory difficulty	Fever and cough 7 days before admission	No
8.	Italy	Case 2	23	Male	Facial weakness, mastoid pain and lower limb paresthesia	Hypogeusia Areflexia Bilateral facial palsy Sensory ataxia	Fever and sore throat for 10 days before admission	No
9.	Italy	Case 3	55	Male	lower limb weakness, Paresthesia, and neck pain	Areflexia Quadriplegia bilateral facial palsy	Fever and cough for 10 days before admission.	No

10	Italy	Case 4	76	Male	Back pain, lower limb weakness and anosmia	Areflexia Quadriparesis	Dry cough for five days before admission and weakness on ninth day	No
11	Italy	Case 5	64	Male	Cough, asthenia, hyposmia and hypogeusia I followed by proximal weakness and paresthesia	Areflexia paraparesis later on Quadriplegia, facial palsy, bulbar weakness and dysphagia	Cough seven days before onset of neurological symptoms	No
12	Italy	Alberti	71	Male	Paresthesia, Distal weakness progressing to quadriparesis in 3 days	Symmetric limb weakness 2/5 LL and 3/5 UL. Glove and stocking paresthesia and Areflexia	Fever for few days in the previous week	Not Reported
13	Italy	Padroni	70	Female	Paresthesia Asthenia and gait difficulty	4/5 power Areflexia Sensations intact	24 days back fever and cough	No
14	USA	Dinkin	36	Male	Bilateral distal Leg Paresthesia and diplopia	Left eye ptosis Mydriasis and partial 3 <sup>rd</sup> nerve. Bilateral abducent palsy Gait ataxia, hypoesthesia and areflexia	Fever, cough and myalgias four days before admission.	Not Reported
15	Switzerland	Ceon	70	Male	Paraparesis. allodynia, Myalgia, Difficulty in voiding and constipation	Bilateral lower limb Flaccid paraparesis Areflexia in all limbs Planters down going	Myalgia, fatigue, dry cough 10 days before admission	No

16	Morocco	Otmani	70	Female	Tingling and rapidly progressive weakness	Areflexia and quadriplegia	Dry cough and fever three days before admission total 10 days before first symptom	Not Reported
17	Italy	Ottaviani	66	Female	Difficulty walking and fatigue. Rash on hands	Initially symmetric paraplegia UL power 4/5 Unilateral facial palsy areflexia	Mild fever and cough 10 days before presentation	Yes
18	Germany	Pfefferkorn	51	Male	Progressive upper and lower limb weakness Acroparesthesia	2/5 Muscle power with Quadriplegia Areflexia Later, locked in syndrome Bilateral facial Palsy, Bilateral hypoglossal paresis Complete sensory loss	Fever and flu, 02 weeks ago.	Not Reported
19	Germany	Scheidl	54	Female	Paraparesis, Distal numbness and tingling Later on, developed dysphagia	Proximal 3/5 Distal 4/5 Areflexia	PCR positive after positive contact 3 weeks before. No symptoms of cough and fever However, had anosmia and ageusia	Not Reported
20	Iran	Ebrahimzadeh- Case 1	46	Male	Pain, and numbness in distal lower and upper extremities for a week followed by ascending paralysis.	Mild facial nerve palsy on the right side. Muscle Power 4/5 LL progressed to 3/5 UL power 5/5 progressed to 4/5 Areflexia	Sore throat, dry cough, and mild dyspnea 18 days prior to developing neurological symptoms.	Not Reported

21	Iran	Ebrahimzadeh- Case 2	65	Male	Ascending upper and lower extremity weakness and paresthesia.	Muscle Weakness 2/5 proximal and 3/5 distal UL UL power 4/5 Areflexia in lower limbs UL reflexes +1	Fever and cough ten days before PCR	Not Reported
22	USA	Chan-Case 1	68	Male	Gait disturbance Paresthesia hands and feet	4/5 power hip flexors Absent vibratory and proprioceptive sense at the toes and areflexia in LL and present in UL Later, bilateral fascial palsy, dysphagia, dysarthria and neck flexion weakness Dysarthria and Gait problem	Fever and Cough 18 days back	Not Reported
23	USA	Chan - Case2	84	Male	Paresthesia of hand and feet 07 days back 03 days gait disturbance	Power 3/5 proximally, unable to walk independently Gradually progressed bilateral facial palsy Autonomic dysfunction, areflexia in LL and present in UL	23 days before fever and cough	Not Reported
24	Spain	Caamaño	61	Male	Facial Muscles weakness	Bilateral facial nerve palsy with absent blink reflex Rest of the neurological examination including reflexes were normal.	Fever and cough without dyspnea 10 days prior to admission	Not reported

ADIP: Acute Inflammatory Demyelinating Polyneuropathy; AMSAN: Acute Motor Sensory Axonal Neuropathy; AMAN: Acute Motor Axonal Polyneuropathy; CSF: Cerebrospinal fluid; GIT: Gastrointestinal tract; IVIG: Intravenous Immunoglobulins; HRCT; High Resolution Computed Tomography scan; LL: lower limbs; ;MRC: Medical Research Council; MRI: Magnetic Resonance Imaging; PCR: Polymerase Chain Reaction; PLEX: Plasma Exchange; UL; upper Limb

Table 2: Details of the diagnostics, management, and outcomes of COVID-19 related GBS

S/No	Country	Associated features and Co morbid	CSF / Ganglioside antibody /MRI/ CT scan findings	CT chest findings	EMG/NCS Findings	PCR for COVID-19	Respiratory failure	Mechanical Ventilation	Management	Outcomes
1.	China	Nil	Proteins 124 mg/dl Four cells	Ground glass opacity both lungs	AIDP	PCR Positive on Day 8 of admission	No	No	IVIg	Discharged on day 30 with normal strength and reflexes
2.	Iran	Diabetes Mellitus	Not done	Diffuse consolidation, Ground glass opacity and bilateral pleural effusions	AMSAN Day nine	PCR Positive before admission	No	No	IVIg	Not Reported
3.	France	Nil	1.66 g/dl proteins and normal cells. Ganglioside antibodies negative	Ground glass opacity both lungs	AIDP Day five	PCR Positive before admission	Yes	Yes	IVIg	Not Reported

4.	USA	Antibiotic induced colitis	Not done	Bilateral basal opacity in lungs Whole spine imaging normal	Not done	Initially PCR was positive for Rhinovirus. On Repeat test COVID-19 PCR was positive	Yes	Yes	IVIG	Weaned off from Ventilator on day 4. Discharged to rehabilitation
5.	Spain case 1	Asthma	GD1b-IgG positive in serum CSF analysis: proteins 80mg/dl and 0 cells	Chest X ray normal	Not done	PCR positive	No	No	IVIG	Complete recovery at discharge. Anosmia and agnosia persisted
6.	Spain case 2	Nil	CSF analysis: 2 cells and 62 mg/dl proteins CSF PCR negative for Covid-19	Chest x ray normal	Not done	PCR positive	No		No	Complete recovery with no residual deficit at discharge Ageusia also resolved

7.	Italy	Nil	Protein level, 101 mg/dl;  Cells 4 per mm <sup>3</sup> ;  Negative CSF PCR  Ganglioside AB negative	Bilateral interstitial pneumonia	AMSAN	PCR positive	Yes	Non- Invasive Ventilation	IVIG (two sessions)	Minimal improvement
8.	Italy	Nil	Proteins 123mg/dl  No cells  Negative CSF PCR  MRI focal contrast enhancement in	CT chest was normal	AMSAN	PCR positive	No	No	IVIG	Discharged

			internal acoustic meatus							
9.	Italy	Nil	Proteins 193 mg/dl No cells Negative CSF PCR  Ganglioside AB negative	Bilateral ground glass opacity	AMAN Variant	PCR positive	Yes	Yes	IVIG two sessions	Still critical at the time of publication  Poor outcome
10.	Italy	Nil	Normal proteins and no cells Negative CSF PCR	Normal	AIDP Variant	PCR positive	No	No	IVIG	Undergoing Rehab at the time of publication
11.	Italy	Nil	proteins 40mg/dl Cell count 3 Negative CSF PCR	Interstitial pneumonia	AIDP Variant	PCR Negative. Serology was Positive for COVID- 19	Yes	Yes	IVIG followed by PLEX	Patient was on ventilatory support at the time of publication

			Ganglioside Ab negative							
12.	Italy	HTN, Aortic aneurysm repair and lung cancer treated by surgery alone	CSf 9 cells and proteins 54 mg/dl CSF PCR negative	Multiple bilateral ground glass opacity and consolidation	AIDP Variant	PCR positive	Yes	CPAP with Prone Positioning	IVIG	Expired
13.	Italy		Csf proteins 48 mg/dl and 1 cell	Some ground glass areas in both lungs	AIDP	PCR positive	Yes	Yes	IVIG	Not Reported
14.	USA		Not done MRI showed enhancement of 3 <sup>rd</sup> nerve Ganglioside antibody negative	X ray chest Normal	Not done	PCR Positive	No	No	IVIG	Partial recovery at the time of discharge

15.	Switzerl and		Proteins was raised no values provided CSF PCR negative Ganglioside Ab negative MRI no evidence of myelopathy	Chest x ray normal	AIDP	PCR Positive	No	No	IVIG	Day 11 patient Discharged to Rehab facility
16.	Morocco	rheumatoid arthritis	Proteins 1gm/l and normal cells CSF PCR negative	Ground glass opacity left lung	AMSAN	PCR positive	No	No	IVIG	No improvement
17.	Italy	Mild Hypertension	Proteins 108mg/dl No cells CSF PCR negative	Bilateral ground glass opacity	Demyelination with axonal damage likely mixed picture	CSF PCR negative Antiglycolipid e Ab negative	Yes	Yes	IVIG	critical

18.	German y		Normal proteins 9 cells in CSF. Repeat CSF proteins high CSF PCR negative Ganglioside AB negative MRI spine showed enhancement of spinal nerve roots	Bilateral interstitial infiltrates	AIDP	Nasal swab PCR +	Yes	Yes	IVIG followed by PLEX	Still on mechanical ventilation but showing signs of motor improvement and Undergoing Rehabilitation
19.	German y		Increase proteins 140g/L and normal cells MRI cervical spine is normal	Chest X ray normal	AIDP	PCR positive	No	No	IVIG	Complete Recoverey Discharged

20.	Iran	Nil	78mg/dl Proteins 4 I cells Gq1b antibody negative Brain and spine MRI Normal	Multiple ground glass opacity in both the lungs	AIDP	PCR Positive	No	No	No active treatment	Muscle Power improved to near normal and discharged.
21.	Iran	Hypertension	Not done Gq1b antibody negative	HRCT positive Details not provided	AIDP	PCR Positive	No	No	IVIG	Muscle power improved to 4+/5. Discharged
22.	USA		226mg/dl proteins 3 cells Ganglioside Ab negative CSF PCR negative		Not done	PCR Positive	No	No	PLEX	Discharged to Rehabilitation. Can ambulate with minimal assistance. Dysphagia resolved

23.	USA	Nil	67mg/dl I protein, 1 cell count CSF PCR negative Ganglioside Ab GM2 IgG/IgM +	Not done	Not done	PCR Positive	Yes	Yes	PLEX followed by IVIG	Quadriplegic with intermittent autonomic dysfunction.  Being weaned from the ventilator
24.	Spain		Mildly elevated levels of proteins (44 mg/dL), absent leukocytes and a negative PCR for COVID-19 CT scan and brain MRI normal	X ray chest pneumonia	Not done	PCR Positive	No	No	Low dose oral Prednisolone	No significant improvement in facial muscle weakness after 2 weeks

ADIP: Acute Inflammatory Demyelinating Polyneuropathy; AMSAN: Acute Motor Sensory Axonal Neuropathy; AMAN: Acute Motor Axonal Polyneuropathy; CSF: Cerebrospinal fluid; GIT: Gastrointestinal tract; IVIG: Intravenous Immunoglobulins; HRCT; High Resolution Computed Tomography scan; LL: lower limbs; ;MRC: Medical Research Council; MRI: Magnetic Resonance Imaging; PCR: Polymerase Chain Reaction; PLEX: Plasma Exchange; UL; upper Limb

Table 3: comparison of COVID-19 associated GBS with Zika associated GBS

S No	Parameters	Zika Associated GBS – Puerto Rico <sup>44</sup>	Zika Associated GBS <sup>48</sup>	COVID-19 associated GBS
1.	Number of reported cases	71	23	24
2.	Mean Age	54 Years	61 Years	60 Years
3.	Gender Distribution females	37(52.1)	8(34)	6(25%)
4.	Facial weakness	44(62%)	9(39%)	9(37%)
5.	Dysphagia	38(53%)	16(70%)	2(8%)
6.	Cough	3(4.2%)		21(87%)
7.	Shortness of breath	33(46.5%)	Not mentioned	
8.	Hyporeflexia/areflexia	71(100)	23(100%)	23(99%)
9.	Antecedent illness to neurological signs	7 (0-21 )	5.9 (1.5–6.5)	11(3-28)
10.	Antecedent illness fever	28(39.4)	5(22%)	18(72%)
11.	Elevated proteins in CSF	49/52(94.2%)	Not reported	16(80%) Not done in 4 Normal in 4
12.	ICU admission	47(66.2%)	14(61%)	9(36%)
13.	Mechanical ventilation	22(31%)	10(43%)	9(36%)
14.	Outcomes and discharge to rehab/nursing home	35 (49.3)	Not mentioned	3 still critical 2 no improvement 3 not reported
15.	Discharge home	32 (45.1)	Not mentioned	16
16.	Death	2 (2.8%)	2	1
