ABSTRACT

Objective: To investigate the clinical characteristics and outcomes of Coronavirus Disease of 2019 (COVID-19) patients complicated with venous thromboembolism (VTE)

Method: We performed a comprehensive literature search of several databases to find studies that assessed VTE in hospitalized COVID-19 patients with a primary outcome of all-cause mortality and secondary outcomes of intensive care unit (ICU) admission and mechanical ventilation. We also evaluated the clinical characteristics of VTE sufferers.

Results: Eight studies have been included with a total of 1237 pooled subjects. Venous thromboembolism was associated with higher mortality (RR 2.48 (1.35, 4.55), $p=0.003$; I^2 5%, $p=0.35$) after we performed sensitivity analysis, ICU admission (RR 2.32 (1.53, 3.52), $p<0.0001$; I^2 80%, $p<0.0001$), and mechanical ventilation need (RR 2.73 (1.56, 4.78), $p=0.0004$; I^2 77%, $p=0.001$). Furthermore, it was also associated to male gender (RR 1.21 (1.08, 1.35), $p=0.0007$; I^2 12%, $p=0.34$), higher white blood cells count (MD 1.24 (0.08, 2.41), 0.04; I^2 0%; 0.26), D-dimer (MD 4.49 (2.74, 6.25), $p<0.00001$; I^2 67%, $p=0.009$) and LDH levels (MD 70.93 (19.33, 122.54), $p<0.007$; I^2 21%, $p=0.28$). In addition, after sensitivity analysis was conducted, VTE also associated with older age (MD 2.79 (0.06, 5.53), $p=0.05$; I^2 25%, $p=0.24$) and higher CRP levels (MD 2.57 (0.88, 4.26); $p=0.003$; I^2 0%, $p=0.96$).

Conclusion: Venous thromboembolism in COVID-19 patients was associated with increased mortality, ICU admission, and mechanical ventilation requirement. Male gender, older age, higher levels of biomarkers, including WBC count, D-Dimer, and LDH were also being considerably risks for developing VTE in COVID-19 patients during hospitalization.

Keywords:

Venous thromboembolism, COVID-19, mortality, ICU admission, mechanical ventilation

Introduction

Coronavirus disease of 2019 (COVID-19) is a highly contagious respiratory disease caused by Severe Acute Respiratory Syndrome Coronavirus type 2 (SARS-CoV-2) resulting in a global pandemic status. As of this paper writing, it has already claimed more than 400.000 lives and infected approximately 7 million people throughout the world (1). As the name implies, many aspects of this multifaceted disease are being explored. Notably, the coagulopathy associated with COVID-19, in which the evidence is still emerging.(2–5)

A previous study has shown that D-dimer, a primary marker of coagulopathy, was associated with higher mortality.(5) Furthermore, lung dissection and autopsy from COVID-

19 decedents showed pulmonary microthrombi formation.(4,6) Therefore, several authors argued that Acute Respiratory Distress Syndrome (ARDS), which is the most common complication of COVID-19, is caused by pulmonary endothelial dysfunction identified as pulmonary intravascular coagulopathy (PIC) or pulmonary thrombosis.(7,8) This argument is substantiated by several findings that the incidence of pulmonary embolism (PE) is more frequent than deep vein thrombosis (DVT).(9)

Data from multiple studies have shown a higher incidence of venous thromboembolism (VTE) in hospitalized COVID-19 patients compared to other diseases.(10,11) This acute vascular complication might potentially affect morbidity and mortality of COVID-19 patients during hospitalization. Nevertheless, a retrospective study conducted by Tang et al. showed that patients with higher D-dimer levels and sepsis-induced coagulopathy (SIC) scores who received heparin have lower mortality rates.(4) However, more prospective studies are needed to confirm this result.

Therefore, the study aimed to systematically investigate the outcomes of hospitalized COVID-19 patients complicated with VTE. We also scrutinized any clinical characteristics which potentially indicated to developing VTE in this population during hospitalization. With this study, we want to determine which COVID-19 patients that have the propensity to develop VTE during hospitalization. Thus, more attention can be given to these patients to reduce morbidity and mortality during hospitalization.

Methods:

Search strategy

The predefined protocol was used for this review and in line with Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA). We systematically searched and identified studies published between 1 January 2020 and 31 May 2020, through electronic searches using MEDLINE, Europe PMC, Proquest, Ebscohost, Google Scholar, Cochrane Central, Clinicaltrial.gov and from preprint websites (Preprint.org and MedRxiv.org). We used Medical Subject Headings (MeSH) and free word to construct our search terms related to venous thromboembolism (venous thromboembolism OR deep vein thrombosis OR pulmonary embolism), coronavirus disease of 2019 (COVID-19 and SARS-CoV-2). We identified articles eligible for further review by performing screening of identified titles or abstracts, followed by a full-text review. In the case of multiple publications, the most recent and complete report was included. We finalized the systematic literature review search on 31 May 2020. This study adhered to the PRISMA guideline.

Selection criteria

Articles eligibility was assessed by two independent investigators (JH and ICSP). Discrepancies were resolved by consensus with a third investigator (AC). The inclusion criteria of the article in this study included all research studies involving hospitalized COVID-19 patients experiencing VTE (DVT group and PE group only, non-specified VTE group, and specified VTE group). We excluded commentaries, non-research letter, reviews, and case reports/case series.

Data extraction

A standardized form was used to collect the information that consists of qualitative aspects of identified studies (the first author and publication year, geographic locations, and study design), COVID-19 patients' profile (gender and age), venous thromboembolisms, and comorbidities. Two authors performed data extraction independently (JH and ICSP). The primary outcome of interest was all-cause mortality, and the secondary outcomes of interest were intensive care admission and mechanical ventilation. In addition, we also extracted data regarding clinical characteristics (patient characteristics, comorbidities, sign and symptoms, and laboratory findings). Data that was reported other than mean \pm SD was transformed accordingly using the formula created by Wan et al.(12)

Statistical analysis

We performed meta-analysis using Review Manager 5.4 (<https://training.cochrane.org/online-learning/core-software-cochrane-reviews/revman>). For dichotomous variables, we calculated the pooled estimates and its 95% confidence interval in the form of risk ratios (RRs) using the Mantel-Haenzel formula. We calculated the pooled estimates for continuous variables in the form of a mean difference (MD) and its standard deviation. To account for interstudy variability regardless of the heterogeneity, we used a random-effects model. We used two-tailed p values with a significance set at ≤ 0.05 . To assess heterogeneity across studies, we used the inconsistency index (I^2) with a value above 50% or $p < 0.05$ indicates significant heterogeneity. We performed a sensitivity analysis using the leave-one-out method to achieve statistical robustness and find the source of heterogeneity. Finally, to qualitatively detect publication bias, we used an inverted funnel-plot analysis.

Results

Study selection and characteristics

Initial systematic database search yielded 365 studies, of which 192 remain after duplicates were excluded. Through title/abstract screening, 170 studies were excluded and left with 22 remaining studies. The final 22 studies were assessed for full-text eligibility, of which 15 of them were excluded due to: one was editorial, two were case reports, three were case-series, one study of PE in non-COVID-19 patients, one study in outpatient COVID-19 patients, and six studies in ICU admitted COVID-19. As a result, only eight studies (n= 1237 subjects) were included in the qualitative and quantitative synthesis.(13–19) (Figure 1, Table 1)

Venous thromboembolism and primary outcome

The initial meta-analysis showed that complication of VTE in COVID-19 patients was not associated with higher mortality (RR1.63 (0.63, 4.24); $p=0.31$; I^2 64%, $p= 0.04$). However, the result was significant after sensitivity analysis was conducted, by excluding one study (Poyiadji et al.); (RR 2.48 (1.35, 4.55), $p=0.003$; I^2 5%, $p=0.35$). (Table 2, Figure 2 and 3)

Venous thromboembolism and secondary outcome

Venous thromboembolism in patients with COVID-19 was significantly associated with higher ICU admission (RR 2.32 (1.53, 3.52), $p<0.0001$; I^2 80%, $p <0.0001$). This result is still consistent after performing sensitivity analysis by excluding study by Middeldorp et al., in addition to lower heterogeneity (RR 2.09 (1.38, 3.16), $p=0.0005$; I^2 70%, $p=0.003$). (Table 2, figure 4 and 5) Furthermore, VTE occurrence indicated the more need for mechanical ventilation support during hospital stay (RR 2.73 (1.56, 4.78), $p=0.0004$; I^2 77%, $p=0.001$). A similar expected result, along with reduced heterogeneity, was noted after a sensitivity analysis was performed, excluding study by Poyiadji et al. (RR 3.35 (2.48, 4.53), $p<0.00001$; I^2 17%, $p= 0.30$). (Table 2, figure 6 and 7)

Clinical characteristics associated with VTE

There were 27 variables consist of patient characteristics, comorbidities, VTE risk factors, signs and symptoms, and laboratory findings have been analysed (Table 3 and Table 4). However, there were only 8 variables associated with VTE, and three of them only included two studies.

The meta-analysis showed that the incidence of VTE in COVID-19 patients were more common in men (RR 1.21 (1.08, 1.35), $p=0.0007$; I^2 12%, $p=0.34$). Sensitivity analysis

by excluding one study (Rodriguez) showed that heterogeneity could be reduced while maintaining significance. (RR 1.25 (1.12, 1.39), $p < 0.0001$; I^2 0%, $p = 0.55$) Even though it was not associated with older age (MD 1.61 (-1.44, 4.66), $p = 0.30$; I^2 52%, $p = 0.04$), sensitivity analysis by excluding study by Poyiadji et al. redirected that older age contributed to increased risk for developing VTE during hospitalization (MD 2.79 (0.06, 5.53), $p = 0.05$; I^2 25%, $p = 0.24$).

Additionally, higher levels of white blood cell (WBC) count (MD 1.24 (0.08, 2.41), 0.04; I^2 0%; 0.26), D-dimer (MD 4.49 (2.74, 6.25), $p < 0.00001$; I^2 67%, $p = 0.009$) and LDH levels (MD 70.93 (19.33, 122.54), $p < 0.007$; I^2 21%, $p = 0.28$) were also associated with VTE complications in COVID-19. Sensitivity analysis on D-Dimer by excluding a study by Poyiadji et al. revealed that heterogeneity can be reduced, an indication of statistical robustness (RR 3.79 (2.26, 5.31), $p < 0.00001$; I^2 39%, 0.16). Higher CRP levels also associated with VTE after we performed sensitivity analysis by excluding the Rodriguez et al. study (MD 2.57 (0.88, 4.26); $p < 0.003$; I^2 0%, $p = 0.96$). Other parameters including neutrophils count and neutrophil-lymphocyte ratio might be potentially associated with VTE in COVID-10 (Table 4). However, CRP levels and these variables were only available in two studies (Figure 7).

Subgroup analysis

We only carried out subgroup analysis consisted of DVT only, PE only, and unspecified VTE group in correlation to ICU admission. Other subgroup analyses for mortality and mechanical ventilation were unable to be conducted due to two subgroups (DVT and VTE) contained less than two studies. As a result, the DVT only group was not associated with ICU admission (RR 2.47 (0.71, 8.59), $p = 0.16$; I^2 54%, $p = 0.14$). Whereas in contrast, higher ICU admission were significant in the PE only group (RR 1.75 (1.13, 2.69), $p = 0.01$; I^2 74%, $p = 0.009$) and in unspecified VTE group (RR 5.50 (2.09, 14.49), $p < 0.00001$; I^2 0%, $p = 0.39$). However, considerable heterogeneity between subgroups was noted (I^2 75.9%, $p = 0.02$). (Figure 8)

Publication bias

We did not perform publication bias in accordance to the Cochrane handbook reference which stipulates that the power of inverted funnel-plot analysis is too low to discriminate the chance from real asymmetry if the included studies are less than 10.(21)

Discussions:

Coagulopathy and VTE in COVID-19 are an emerging phenomenon with devastating consequences and has been associated with poor prognosis in COVID-19.(22,23) Thus, it prompts International Society of Thrombosis and Haemostasis (ISTH) to publish interim guidelines for managing COVID-19's coagulopathy.(24) They recommend that all hospitalized COVID-19 patients, should be prophylactically anticoagulated.

The underlying factors contributed to VTE according Virchow's triad, which are venous stasis, activation of coagulation, and vascular dysfunction.(25) The first factor, venous stasis, is common due to immobilization in hospitalized patients, especially patients that reside in the ICU. Nonetheless, the incidence of VTE in ICU-admitted COVID-19 patients were higher compared to other diseases.(10,11)

The other two factors are culmination of COVID-19 infection. SARS-CoV-2 can infect different organs through angiotensin-converting enzyme 2 (ACE-2), a glycoprotein metalloprotease that are ubiquitously found in human organs, particularly the endothelial cells, which traversed multiple organs and the pneumocytes.(26,27) The ensuing hypoxia caused by lung injury and ARDS in COVID-19 is a key factor of vascular fibrin deposition due to the increased early growth response-1 (Egr-1), which triggered tissue factor transcription/translation by mononuclear phagocytes and smooth muscle cells.(28) Furthermore, there is a role of bidirectional immunothrombosis, which is heightened inflammation will shift the balance to the procoagulant state by downregulating necessary anticoagulant pathways, while upregulating tissue factor expression necessary for thrombin generation.(29)

In addition, SARS-CoV-2 downregulates ACE-2 after successfully infected cells, which is a counterregulatory enzyme of Angiotensin II (AngII) that maintains the renin-angiotensin system (RAS) balance in check.(30) This condition leads to a prothrombotic milieu. Interaction of AngII with angiotensin II type 1 receptor (ATR-1) will activate transcription factors, which increased adhesion and accumulation of neutrophils and macrophages to endothelial cells, and ultimately these cells will release proinflammatory cytokines and chemokines.(30,31) All of these will preserve the vicious cycle of inflammation and coagulopathy.

SARS-CoV-2 is also known to cause direct vascular injury via ACE-2 receptors. Case series of post mortem analysis of decedents due to COVID-19 confirmed diffuse endothelial inflammation, termed endothelitis, viral elements within endothelial cells, and inflammatory cell death.(32) Furthermore, morphologic and molecular changes from autopsied decedents due to COVID-19 ARDS showed severe endothelial injury with viruses present

intracellularly and disrupted cell membranes.(33) Another hallmark feature was thrombosis and microangiopathy and intussusceptive angiogenesis, which was nine times and 2.7 times more common than patients with influenza.(34)

To the best of our knowledge, this is the first systematic review and meta-analysis that describes the clinical characteristics and outcomes associated with VTE in COVID-19 patients. The meta-analysis has shown that VTE was significantly associated with mortality compared to the non-VTE group after sensitivity analysis, by excluding Poyiadji et al. Of note, higher all-cause mortality was seen in non VTE COVID-19 patients in this study.

This finding is in accordance with a study from China by Wang et al., involving 1026 subjects with laboratory-positive COVID-19 that showed a high risk of thromboembolism, defined as Padua score of ≥ 4 , which is significantly associated with mortality.(35) Despite pooling mortality risk ratio across all VTE phenomena, which might introduced bias due to mortality disparity between PE only group and DVT only group, a study by Zhang et al. showed that COVID-19 patients with DVT had significant risks of developing adverse outcomes consist of more ICU admission ($p=0.005$), fewer hospital discharges ($p<0.001$), and more deaths ($p=0.001$).⁽¹⁸⁾ Thus, it is justified to include DVT under the same umbrella term of VTE with PE. Furthermore, Wang et al. also showed that these patients were more likely to have been admitted to the ICU.⁽³⁵⁾ We also find this association to be true. In comparison to the non-VTE group, the VTE group was significantly associated with higher ICU admission. Also, our data showed that VTE patients were likely to be mechanically ventilated, confirming aforementioned study.⁽³⁵⁾

However, it is worth mentioning, that one of the included studies highlighted that 72% pulmonary embolism cases was diagnosed in patients who do not need ICU level care.⁽¹⁵⁾ In addition, Rodriguez et al. reported that asymptomatic DVT was diagnosed in 23 out of 156 patients (14.7%).⁽¹⁷⁾ Thus, special attention is needed for asymptomatic or ambulatory COVID-19 patients.⁽²²⁾

It is well known that worse clinical presentations of COVID-19 disproportionately affect the older population and male gender. However, the pathomechanisms remain elusive. In our meta-analysis, the male gender was associated with VTE. This result might explain, in part, why males were disproportionately affected. Nonetheless, men do have a higher risk of first and recurrent VTE compared to women, and it is hypothesized due to X or Y link mutation or mutation on a gene with a sex-specific effect.⁽³⁶⁾

In our meta analysis, VTE was associated with the older population after we performed sensitivity analysis, by excluding Poyiadji.⁽¹⁵⁾ In his study, VTE occurred in

younger patients. Younger populations in VTE sufferers were also noted in studies by Artifoni et al. and Rodriguez et al.(13,17) However, it is important to keep in mind that analysis from a population-based study of 25 years involving 2218 patients, with increasing age, there is a marked increase in VTE incidences in both sexes.(37)

Previously, a meta-analysis by Tian, et al. found that higher WBC count, D-Dimer, CRP, and LDH levels were associated with mortality in COVID-19.(38). These biomarkers serve as an indicator of heightened inflammation and organ damages. Thus, in the setting of marked inflammation, the bidirectional role of immunothrombosis plays a crucial part in VTE's pathomechanism. In our meta-analysis, higher WBC count, D-Dimer, CRP, and LDH levels were associated with VTE. However, the CRP variable gains significance after we only included two studies.(table 4) Therefore, more prospective studies are needed to better understand the relevance of CRP levels as a risk marker .

On the other hand, our meta-analysis did not yield any association between VTE and comorbidities. Therefore, another likely explanation of why there is a higher burden of COVID-19 in patients with comorbidities.(30,39) Furthermore, it is not surprising that symptoms and signs other than dyspnea were not associated with VTE. Also, dyspnea in COVID-19 is not adequately sensitive to distinguish pulmonary embolism (VTE spectrum) from the lung injury, which is the main target organ of SARS-CoV-2.

We did not find any association between platelet count and VTE, confirming findings that coagulopathy in COVID-19 is a distinct entity compared to disseminated intravascular coagulation (DIC).(40) The thrombosis phenomena in COVID-19 occurred on an earlier phase, thus do not reflect the state of consumptive coagulopathy.(7,9,41,42)

Finally, we can not confirm other analyzed variables that were and were not associated with COVID-19 due to only including two studies. Thus, more prospective studies are needed.

Limitations:

This systematic review and meta-analysis have several limitations. First, although the total subjects pooled from eight studies were adequate (n= 1237 subjects), it is worth noting that the reported VTE phenomena are not homogeneous. Two studies reported VTE, four studies reported PE only, and two studies reported DVT only. Second, not all of the studies reported the outcome of interest (mortality, ICU admission, and mechanical ventilation). Thus, we can only perform a subgroup analysis for ICU admission. Third, due to many missing data from included studies, more studies are needed to confirm meta-analysis findings that consisted of

two studies. Thus, we can not fully elucidate the representative clinical characteristics associated with VTE in COVID-19 patients. Lastly, most of the studies were from western countries, so findings may not be generalizable for other populations. Finally, the included studies were predominantly retrospective design.

Conclusions:

Venous thromboembolism in patients with COVID-19 contributed significantly to higher in-hospital mortality, ICU admission and the need of mechanical ventilation. Additionally, male gender, older age, as well as higher levels of WBC count, D-Dimer, and LDH were associated with increased risks of developing VTE in COVID-19.

Table 1. Characteristics of included studies

Author	Country	Study design	Sample size	VTE/PE/DVT (%)	Age (mean±SD)	Male (%)	Hypertension (%)	Diabetes Mellitus (%)	Smoking (%)	COPD/respiratory disease (%)	Primary Outcome	Secondary Outcome
Mathieu Artifoni	France	Retrospective cohort	71	VTE; 16 (22,54)	60.2 ± 36.5 vs 62.2 ± 30.6	11/16 (68.7) vs 32/55 (58.2)	3/16 (19) vs 26/55 (47)	0/16 (0) vs 14/55 (25)	0/16 (0) vs 6/55 (12)	NA	Mortality	ICU admission Mechanical ventilation
Saskia Middeldorp	Netherlands	Retrospective cohort	198	VTE; 39 (19,7)	62 ± 10 vs 60 ± 15	27/39 (69) vs 103/159 (65)	NA	NA	NA	NA	NA	ICU admission
Ian Leonard Lorant	France	Retrospective cohort	106	PE; 32 (30,19)	64 ± 22 vs 63 ± 15	25/32 (78) vs 45/74 (57)	NA	NA	NA	NA	NA	ICU admission
Neo Poyiadji	USA	Retrospective cohort	328	PE; 72 (21,95)	59 ± 15 vs 62 ± 16	35/72 (49) vs 115/256 (45)	41/72 (57) vs 156/256 (61)	29/72 (40) vs 97/256 (38)	20/72 (28) vs 33/256 (13)	5/72 (7) vs 102/256(40)	Mortality	ICU admission Mechanical ventilation
Franck Grillet	France	Retrospective cohort	100	PE; 23 (23)	67 ± 11 vs 66 ± 13	21/23 (91) vs 49/77 (64)	NA	6/23 (23) vs 14/77(18)	NA	4/23 (17) vs 10/77 (13)	NA	ICU admission
Florian Bompard	France	Retrospective cohort	135	PE; 32 (23,7)	68.6 ± 20 vs 63.3 ± 25.27	26/32 (81) vs 68/103 (66)	NA	NA	NA	NA	NA	ICU admission Mechanical ventilation
P. Demelo-Rodríguez	Spain	Prospective cohort	156	DVT; 23 (14,7)	66.7 ± 15.2 vs 68.4 ± 14.4	14/23 (60.9) vs 88/133 (66.2)	NA	NA	NA	NA	NA	ICU admission
Liming Zhang	China	Cross Sectional	143	DVT; 66 (46.1)	67 ± 12 vs 59 ± 16	36/66 (54.5) vs 38/77 (49.4)	28/66 (42.4) vs 28/77 (36.4)	13/66 (19.7) vs 13/77 (16.9)	5/66 (7.6) vs 4/77 (5.2)	5/66 (7.6) vs 4/77 (5.2)	Mortality	ICU admission Mechanical ventilation

a. VTE; venous thromboembolism, PE; pulmonary embolism, DVT; deep vein thrombosis, COPD; chronic obstructive pulmonary disease, NA; not available

Table 2. Summary of meta-analysis of primary and secondary outcomes

Variable	Risk Ratio (95%CI); <i>p</i> -value	Heterogeneity (<i>I</i> ² , <i>p</i> -value)	Number of Studies
<i>Primary Outcome</i>			
Mortality	1.63 (0.63, 4.24); 0.31	64%; 0.04	4
Mortality SA ^a	2.48 (1.35, 4.55); 0.003	5%; 0.35	3
<i>Secondary Outcomes</i>			
ICU Admission	2.32 (1.53, 3.52); <0.0001	80%; <0.0001	7
ICU Admission SA ^a	2.09 (1.38, 3.16); 0.0005	70%; 0.003	6
Mechanical Ventilation	2.73 (1.56, 4.78); 0.0004	77%; 0.001	4
Mechanical Ventilation SA	3.35 (2.48, 4.53); <0.00001	17%; 0.30	3

a. CI; confidence interval, SA; sensitivity analysis by leave-one-out method

Table 3. Summary of meta-analysis of demographic profiles, comorbidities, and clinical manifestations.

Variable	Risk Ratio (95%CI)/ Mean Difference (SD) ^a ; <i>p</i> -value	Heterogeneity (<i>I</i> ² ; <i>p</i> -value)	Number of Studies
<i>Patient Characteristics</i>			
Gender, male	1.21 (1.08, 1.35); 0.0007	12%; 0.34	8
Gender, male SA	1.25 (1.12, 1.39); <0.0001	0%; 0.55	7
Age (years)	1.61 (-1.44, 4.66); 0.30	52%; 0.04	8
Age (SA)	2.79 (0.06, 5.53); 0.05	25%; 0.24	7
<i>Comorbidities</i>			
DM	1.09 (0.80, 1.50); 0.58	8%; 0.35	4
Arterial hypertension	0.94 (0.67, 1.31); 0.70	46%; 0.16	3
CVD	1.20 (0.75, 1.91); 0.45	0%; 0.81	2
Smoking	1.75 (0.88, 3.47); 0.11	21%; 0.28	3
Active Cancer	0.94 (0.58, 1.51); 0.79	0%; 0.85	5
BMI	-0.28 (-1.30, 0.73); 0.58	18%; 0.30	4
COPD / pulmonary disease	0.67 (0.14, 3.19); 0.61	85%; 0.001	3
<i>Risk factors of VTE</i>			
Prior surgery within 3 months	1.74 (0.54, 5.56); 0.35	0%; 0.65	2
Prior VTE	1.65 (0.88, 3.08); 0.12	0%; 0.92	3
<i>Symptoms</i>			
Fever	1.05 (0.92, 1.19); 0.46	16%; 0.28	2
<i>Sign</i>			
Temperature ^d	0.22 (-0.11, 0.55); 0.20	0%; 0.41	2

- a. All values are positive unless there is (-) symbol; positive values refer to increase, and negative values refer to decrease
- b. CI; confidence interval, SD; standard deviation, SA; Sensitivity analysis by leave-one-out method
- c. DM; diabetes mellitus, CVD; cardiovascular disease, BMI; body mass index, COPD; chronic obstructive pulmonary disease, VTE; venous thromboembolism
- d. Temperature in celcius

Table 4. Summary of meta-analysis of laboratory findings

Variable	Mean difference (SD) ^a ; <i>p</i> -value	Heterogeneity (I ² , <i>p</i> -value)	Number of Studies
<i>Laboratory Findings</i>			
Hemoglobin (g/dL)	-0.04 (-0.55, 0.47); 0.87	0%; 0.50	2
White blood cells (10 ⁹ /L)	1.24 (0.08, 2.41); 0.04	0%; 0.26	3
Platelet count (10 ⁹ /L)	7.75 (-13.95, 29.45); 0.48	0%, 0.48	4

Test for subgroup differences: Chi ² = 8.31, df = 2 (P = 0.02), I ² = 75.9%						

FIGURE LEGENDS

Figure 2. Venous thromboembolism (VTE) and mortality.

Caption. There was no difference in all-cause mortality between the VTE group and the non-VTE group.

Figure 3. Venous thromboembolism (VTE) and mortality.

Caption. After excluding one study (Poyiadji et al.), the COVID-19 with VTE was associated with higher all-cause mortality.

Figure 4. Venous thromboembolism and ICU admission.

Caption. ICU admission is higher in COVID-19 patients with VTE compared to the non-VTE group.

Figure 5. Venous thromboembolism and ICU admission.

Caption. After excluding one study (Middeldorp et al.), the heterogeneity can be reduced while maintaining significance.

Figure 6. Venous thromboembolism and mechanical ventilation.

Caption. COVID-19 patients complicated with VTE were associated with higher need of mechanical ventilation.

Figure 7. Venous thromboembolism and mechanical ventilation.

Caption. After excluding one study (Poyiadji et al.), the heterogeneity can be reduced while maintaining significance.

Figure 8. Subgroup analysis of venous thromboembolism and ICU admission.

Caption. COVID-19 patients complicated with PE and VTE, were associated with higher ICU admission. However, considerable heterogeneity and subgroup differences were noted.
