51 Abstract

52

52	
53	Severe malaria (SM) is a major public health problem in malaria-endemic countries. Sequestration
54	of <i>Plasmodium falciparum (Pf)</i> infected erythrocytes in vital organs and the associated
55	inflammation leads to organ dysfunction. MicroRNAs (miRNAs), which are rapidly released from
56	damaged tissues into the host fluids, constitute a promising biomarker for the prognosis of SM. This
57	study applied next-generation sequencing to evaluate the differential expression of miRNAs in SM
58	compared to uncomplicated malaria (UM). Six miRNAs were associated with in vitro Pf
59	cytoadhesion, severity in Mozambican children and Pf biomass. Relative expression of hsa-miR-
60	4497 quantified by TaqMan-RT-qPCR, was higher in SM children plasmas compared to that of UM
61	(p<0.048), and again correlated with <i>Pf</i> biomass (p=0.033). These findings suggest that different
62	physiopathological processes in SM and UM lead to differential expression of miRNAs and pave
63	the way to future studies aiming to assess the prognostic value of these miRNAs in malaria.

76 Introduction

77

78	Case fatality rates for <i>Plasmodium falciparum (Pf)</i> severe malaria (SM) remain unacceptably high
79	in young African children (1). Early detection and prompt treatment of SM are critical to improve
80	the prognosis of sick children. Unfortunately, clinical signs and symptoms in many malaria
81	patients, particularly at the beginning of the infection, may not adequately indicate the potential for
82	the infection to trigger severe or life-threatening disease. Moreover, in malaria-endemic areas,
83	where immunity to malaria is progressively acquired, the detection of peripheral Pf parasitemia in
84	sick children does not necessarily prove that malaria is the cause of the severe pathology observed,
85	given that many individuals may carry parasites without expressing clinical malarial disease (2).
86	
87	Sequestration of <i>Pf</i> infected erythrocytes (iEs) (3) in vital organs is believed to constitute a key
88	pathogenic event leading to SM, as has been shown in post-mortem parasite counts in patients who
89	died with cerebral malaria (CM) (4, 5). This extensive sequestration of parasitized erythrocytes in
90	the microvasculature, together with the production of inflammatory mediators, leads to the
91	dysfunction of one or more peripheral organs, such as the lungs (acute respiratory distress
92	syndrome), kidneys (acute kidney injury) or brain (coma) (6, 7). This tissue-specific tropism of Pf
93	parasites is mediated by the Pf erythrocyte membrane protein-1 (PfEMP1) which can bind to
94	different host receptors on the capillary endothelium, uninfected erythrocytes and platelets (8, 9)
95	such as endothelial receptor of protein C (ePCR), gC1qR, Intercellular adhesion molecule-1, CD36,
96	chondroitin sulfate A or complement receptor 1 (10).

97

Efforts have been made to identify biomarkers of SM which could be used for prevention of the
severity of disease, and for early diagnosis (11). Several biomarkers related to endothelial activation
and immune dysfunction have been associated with different malaria-derived severe pathologies

19th Dec

(11-14). Plasma levels of histidine-rich protein 2 (HRP2), a parasite-specific protein secreted by the 101 102 parasite during its blood cycle, has been used as a biomarker of total parasite biomass (circulating 103 and sequestered parasites) (15, 16) and therefore as a prognostic marker of the total parasite biomass and as a better proxy marker for SM than peripheral parasitemia (16). Organ damage and 104 pathological disease states have also been associated with the rapid release of microRNAs 105 (miRNAs) into the circulation, a class of endogenous small non-coding RNAs (18-24 nucleotides) 106 107 (17). As secreted miRNAs can be detected in biological fluids such as plasma (18), they are currently being explored as promising non-invasive biomarkers to monitor organ functionality and 108 109 tissue pathophysiological status. The content of miRNAs in the host is influenced by host-pathogen 110 interactions (19). Sequestration of erythrocytes infected with *P. berghei* in mice brains has been 111 demonstrated to modify the miRNA expression in cells (20). Similarly, sequestration of P. vivax gametocytes in the bone marrow has been associated with transcriptional changes of miRNAs 112 113 involved in erythropoiesis (21). The aforementioned evidence suggests that *Plasmodium* parasites, although not able to produce miRNAs (22), could affect the production of organ-specific host 114 115 miRNAs, pointing towards the potential of these small molecules to detect SM associated organ injury (23) and to confirm the contribution of malaria in the chain of events leading to death 116 117 through the analysis of postmortem tissues (23).

118

This study was conducted under the hypothesis that miRNA levels in plasma are differentially expressed among children with severe and uncomplicated malaria due to the parasite sequestration in vital organs of severely ill children. To identify promising biomarkers for SM, a small RNA next-generation sequencing (NGS) was applied to select miRNAs that were differentially expressed by human brain endothelial (HBE) cells exposed to *Pf* iEs selected for cytoadhesion to endothelial receptor of protein C, the main host receptor associated with SM (9), compared to those exposed to non-cytoadherent iEs, and non-infected erythrocytes (niEs), as well as by Mozambican children

19th Dec

126	with SM compared to children with uncomplicated malaria (UM) (Figure 1). miRNAs that were
127	differentially expressed in both analyses, together with the Pf biomass-associated miRNAs
128	(correlation coefficient >0.50 (24)), were quantitatively confirmed in an independent validation
129	cohort set of Mozambican children with SM and UM using TaqMan reverse transcriptase
130	quantitative PCRs (RT-qPCRs).
131	
132	Material and Methods
133	
134	Study population
135	
136	Plasma samples used to assess miRNA levels were collected in two case-control studies conducted
137	in Manhiça District (southern Mozambique) during 2006 (N=113) and 2014 (N=91). Briefly, the
138	cases were children under five years of age admitted to the Manhiça District Hospital with SM and
139	controls were outpatient children with UM. Details on SM and UM criteria, case management,
140	sample collection and storage, and laboratory blood analysis are included in the Technical
141	Appendix.
142	
143	The study protocols for each of the two case-control studies from which this analysis was derived
144	were approved by the National Mozambican Ethical Review Committee (Mozambique) and
145	Hospital Clínic (Barcelona, Spain). A signed written informed consent was obtained from all
146	participants' guardian or parent during the original studies.
147	
148	Parasitological determinations

19th Dec

150	Thick and thin blood films were prepared to quantify <i>Pf</i> parasitaemia. Approximately half of a
151	60µL dried blood drop on Whatman-903 filter paper was used to extract parasite DNA followed by
152	a real-time quantitative PCR (qPCR) targeting the Pf 18S rRNA gene (25, 26). HRP2 levels were
153	quantified using commercially available enzyme-linked immunosorbent assay (ELISA) kits and an
154	in-house highly sensitive quantitative bead suspension array (qSA) based on Luminex technology
155	(Technical Appendix).
156	
157	Pf cytoadhesion assays
158	
159	Cytoadhesion assays were performed to discover the differential expression of miRNAs. HBE cells
160	were incubated with Pf-iEs at the trophozoite stage of the ePCR-binding FCR3 strain (ePCR-iE;
161	which expresses the PfEPM1 protein that binds to ePCR receptor) and the 3D7 strain (3D7-iE; a
162	strain without the protein that binds to ePCR receptor). Non-infected erythrocytes were used as
163	negative control. Details on cytoadhesion assays are included in the Technical Appendix. The cell-
164	conditioned media of each group were collected after 1hr (t1) and 24hrs of stimulation (t24) and
165	subjected to RNA extraction followed by small-RNA sequencing.
166	
167	Molecular procedures, gene target prediction and data analysis
168	
169	RNA was extracted from cell-conditioned media (3ml) and plasma samples (1ml) using the
170	miRNeasy tissues/cells kit and miRNeasy Plasma/Serum kit, respectively, with the use of $5\mu g$
171	UltraPure [™] glycogen/sample. Given that the plasma samples were conserved in heparin, RNA was
172	precipitated with LiCl as described elsewhere (27). Purified RNA was subjected to library
173	preparation, pooling and sequencing using a HiSeq 2000 (Illumina) platform following the protocol
174	for small RNAs (28), for more details see the Technical Appendix. A previously published pipeline

19th Dec

175	(28) was used to assess the sequencing quality, identification and quantification of small RNAs,
176	normalization and other species RNA contamination (Technical Appendix). To detect miRNAs and
177	isomiRs, reads were mapped to the precursors and annotated to miRNAs or isomiRs using miRBase
178	version 21 with the miraligner (29). DESeq2 R package v.1.10.1 (R3.3.2) (30) was used to perform
179	an internal normalization.
180	
181	Fifty μ l of plasma from the Mozambican children (2014) with no haemolysis were used for RNA
182	extraction as described above followed by RT-qPCR. Details on RT-qPCR and endogenous controls
183	(ECs) are included in the Technical Appendix. miRNA relative expression levels (RELs) were
184	calculated with the $2^{-\Delta Ct}$ method, where $\Delta Ct = [Ct (miRNA) - Mean Ct (ECs)]$, considering
185	efficiencies of 100% for all the miRNAs and ECs (31).
186	
187	The selected miRNAs were screened through different gene target prediction programs such as
188	DIANA-microT-CDS, MiRDIP, MirGate, and TargetScan (Technical Appendix).
189	
190	Differential expression of miRNAs and isomiRs was assessed using DESEq2 and IsomiRs packages
191	in R (29, 32), for more details see the Technical Appendix. All statistical analyses were performed
192	using R3.3.2 and graphs were prepared with GraphPad (Technical Appendix).

204 miRNA expression by HBE cells

205

206	The ePCR binding <i>Pf</i> strain (FCR3; ePCR-iE) showed higher levels of cytoadhesion to HBE cells
207	(mean of 32.60 iE per 500cells, standard deviation [SD]:4.87) than a non-binding $Pf(3D7; 3D7-iE)$
208	strain (3.20, SD:1.06; p=0.001) and non-infected erythrocytes (3.12, SD:0.39; p=0.001) (Appendix
209	Figure 1). Three replicates of the media collected from each cytoadhesion assay after one (t1) and
210	24 hours (t24) were sequenced, giving a total of more than 200 million reads per lane, with a mean
211	of 12.10 million reads (SD=13.31) per sample (Table 1; Figure 2A; Appendix Table 1). The mean
212	percentage of miRNAs in the media samples analysed was 4.01% (SD=2.93) and a mean of 203
213	(SD=93.82) distinct miRNAs (a minimum of 101 and a maximum of 465) were detected (Appendix
214	Table 1). The ten most expressed miRNAs for all samples at t1 and t24 time points are described in
215	Figure 2B. No contamination with RNA from other species was observed.
216	
217	One hour after incubating the HBE cells with Pf infected and non-infected erythrocytes, 111
218	miRNAs were found to be differentially expressed in cell-condition media of niE and ePCR-iE, 76
219	of them being downregulated and 35 upregulated in ePCR-iE compared to niE (Figure 2C;
220	Appendix Table 2). At this same time point, 100 miRNAs were differentially expressed in cell-
221	condition media of 3D7-iE and ePCR-iE, 67 were downregulated and 33 upregulated in ePCR-iE
222	compared to 3D7-iE (Figure 2D; Appendix Table 3). Overall, 89 miRNAs were differentially
223	expressed in ePCR-iE compared to both niE and 3D7-iE, 28 and 61 of which were upregulated and
224	downregulated, respectively, in ePCR-iE. There were no differentially expressed miRNAs between

Gupta et al

19th Dec

niE and 3D7-iE cell-condition media. At t24, only hsa-miR-451a was significantly upregulated in
cell-condition media of ePCR-iE with respect to niE and 3D7-iE. There were no significantly
different miRNAs found between niE and 3D7-iE cell-condition media. All differentially expressed
isomiRs were from the selected miRNAs and none of them presented any modifications in the seed
region.

230

miRNAs expression in plasmas from Mozambican children with malaria of varying severity 232

Out of 113 plasma samples collected from Mozambican children with SM (N=57) and UM (N=56) 233 234 in 2006, 11 samples were discarded because of haemolysis (N=5; $OD_{414}>0.2$) (33), and because no 235 peak was observed between 133-150 nucleotides (typical size for miRNAs plus library adaptors) on the bioanalyzer results after library preparation (N=6). Among the 102 sequenced samples (SM=53: 236 237 UM=49), 19 samples (9 SM; 10 UM) were further excluded because of the low number of miRNA reads (<10,000 reads). Finally, samples from 83 children (44 with SM and 39 with UM) were 238 239 included in the analysis (Table 2). The characteristics of Mozambican children are presented in Table 2. 240

241

242	The sequencing of the 83 plasma samples yielded a mean of 9.42 million reads (SD=6.4) per
243	sample (Figure 2A; Table 1; and Appendix Table 4). The mean percentage of miRNAs per plasma

samples was 20.5% (SD=13.2), with a mean of 395 (SD=169) distinct miRNAs detected (a

245 minimum of 116 and a maximum of 786; Appendix Table 4). The total number of miRNAs

detected across samples was 1450. The ten most expressed miRNAs can be found in Figure 2B. No

247 contamination with RNA from other species was observed.

19th Dec

249	hsa-miR-122-5p was found upregulated in children with SM (Table 3). In the sub-analysis by signs
250	of severity, five miRNAs were found associated with SA, prostration and ARD (Table 3). Twelve
251	miRNAs were found associated with PM-agglutination and cytoadhesion to g1CqR (Table 3). No
252	associations were observed between miRNA counts and rosetting, CD36 and CD54. After adjusting
253	for multiple comparisons, three (hsa-miR-10b-5p, hsa-miR-378a-3p and hsa-miR-4497) out of the
254	1450 miRNAs (identified in RNA sequencing data) were found to correlate with HRP2 levels
255	determined by qSA (Spearman analysis; Figure 3). Similar correlations were observed when HRP2
256	levels were determined by ELISA (Appendix Table 5). miRNAs were neither associated with
257	hepatomegaly nor with splenomegaly. All differentially expressed isomiRs between children with
258	SM and UM belong to the differentially expressed miRNAs, with no modifications in the seed
259	region.
260	

261 Validation cohort

262

Among the 89 miRNAs differentially expressed in cell-condition media of HBE cells exposed to 263 niE and 3D7-iE compared to ePCR-iE, 5 miRNAs were further confirmed to be differentially 264 expressed between children with SM and UM. These five miRNAs (hsa-miR-122-5p, hsa-miR-265 266 320a, hsa-miR-1246, hsa-miR-1290 and hsa-miR-3158-3p) along with hsa-miR-4497 miRNA, which had a correlation coefficient with HRP2 higher than 0.5 (Figure 3), were selected for 267 TagMan-RT-gPCRs validation in an independent cohort of children with SM and UM recruited in 268 2014. Among the 91 plasma samples collected from these children, 21 were discarded because of 269 haemolysis (OD₄₁₄>0.2) (33). Out of the 70 remaining samples, 40 and 30 samples were collected 270 from children with SM and UM, respectively (Table 2). The characteristics of Mozambican children 271 are presented in Table 2. 272

273

19th Dec

274	All samples tested by RT-qPCR amplified the exogenous control (ath-miR-159a) with a Ct
275	value<18 and a coefficient of variance (CV) <5%, suggesting the correct RNA extraction and
276	cDNA preparation. hsa-miR-191-5p (CV=4.8%, basemean=3953.3, log ₂ fold change (FC)=-0.02 and
277	SD=0.56), hsa-miR-30d-5p (CV=4.9%, basemean=14172.31, FC=0.01 and SD=0.61) and hsa-miR-
278	148a-3p (CV=5%, basemean=111593.08, FC=0.11 and SD=0.82) were selected as a panel of ECs
279	for RT-qPCR analysis. Among these three, the NormFinder stability value was 0.044 for the
280	combination of hsa-miR-30d-5p and hsa-miR-191-5p, and were thus selected as ECs. No
281	statistically significant differences were found when Ct values of exogenous and two endogenous
282	controls were compared between SM and UM samples (Appendix Figure 2). Standard curves for all
283	miRNAs (ECs and selected miRNAs) were performed, giving efficiencies between 91.1% - 103.8%
284	(Appendix Table 6), which were assumed as 100% to calculate the relative expression values using
285	the $2^{-\Delta Ct}$ method (31).

286

The relative expression levels of hsa-miR-3158-3p and hsa-miR-4497 were significantly higher in 287 288 children with SM than UM (p<0.05) as shown in Figure 4. hsa-miR-3158-3p levels were higher in children with prostration, multiple seizures and ARD compared to UM (p<0.05; Figure 5). Severe 289 anaemia and ARD symptoms were associated with higher hsa-miR-4497 levels (p<0.05; Figure 5). 290 291 No such associations were observed for CM and hypoglycaemia. RELs of hsa-miR-3158-3p and 292 hsa-miR-4497 were found positively correlated with HRP2 levels quantified by qSA (p<0.05; Figure 6), with similar correlations observed when HRP2 levels were determined by ELISA 293 (Appendix Table 5). 294

295

296 miRNA gene target prediction

19th Dec

298	A total of 87 putative targets for hsa-miR-3158-3p and hsa-miR-4497 miRNAs were identified,
299	none of which were shared by both miRNAs (Appendix Table 7). Forty-five experimentally
300	validated mRNA targets were predicted for hsa-miR-3158-3p and 42 for hsa-miR-4497. The
301	predicted targets were found to be involved in a broad range of biological processes (Appendix
302	Table 8). However, significance was lost when adjusted by the Benjamini-Hochberg method. None
303	of the target genes were clustered under the KEGG pathway with p value <0.05.
304	
305	Discussion
306	
307	As microRNAs can reflect disease states and organ damage due to their specificity to cell type (17),
308	they have the potential to provide a new screening method for early detection of pathological Pf
309	sequestration and may consequently become an effective prognosis tool for severe malaria.
310	Moreover, the detection of miRNAs associated with organ damage in host biofluids may provide an
311	alternative to post-mortem autopsies for determining the presence of parasites in host vital organs.
312	This approach creates new opportunities to develop malaria diagnostic tools that can guide
313	treatment decisions, and to understand the role of human miRNAs in several disease conditions
314	(23).
315	
316	In the discovery phase, 89 miRNAs were found to be differentially expressed in the media of HBE

cells after incubation with an ePCR-cytoadherent *Pf* strain as compared with non-cytoadherent
parasites and non-infected erythrocytes. In addition, fifteen miRNAs in plasma samples obtained
from Mozambican children were associated with SM, with specific severity symptoms, and with the
cytoadherent *Pf* phenotype, compared to UM and non-cytoadherent parasites. In the validation
phase, the higher abundance of hsa-miR-3158-3p and hsa-miR-4497 in SM children compared to
children with UM was further confirmed. Prostration, multiple seizures, SA and ARD symptoms of

19th Dec

severity were associated with higher levels of hsa-miR-3158-3p and hsa-miR-4497. hsa-miR-4497 323 324 levels were also positively correlated with the parasite biomass as quantified by the levels of HRP2 both in the discovery and validation phases. Overall, these findings suggest that different 325 physiopathological processes in SM and UM lead to differential expression of miRNAs in plasma. 326 327 HBE cells released a high number of the miRNAs when they were stimulated with an ePCR-328 329 binding *Pf* strain within the first hour of incubation. After 24 hours the system stabilizes and only one miRNA (hsa-miR-451a) was found at higher levels in cell-conditioned media of HBE cells 330 incubated with an ePCR-binding strain compared to cells stimulated with non-adherent (3D7-iE) or 331 332 non-infected erythrocytes. miR-451 has been implicated in translocation to form a chimera with 333 Plasmodium mRNAs to block their translation (34), and also found to be abundant in sickle erythrocytes (35). In addition, it was shown that parasites could reduce miR-451 levels in host 334 335 fluids (36). However, it was not confirmed in plasmas from Mozambican children in this study. Five miRNA levels were higher in children with SM and severity symptoms (prostration, SA and 336 ARD) compared to UM cases. Pf cytoadhesion phenotypes (PM-agglutination and cytoadhesion to 337 gC1qR) were also associated with the differential expression of miRNAs, suggesting that the 338 339 interaction between PfEMP1 and host receptors leads to the secretion to plasma of specific 340 miRNAs. Moreover, three miRNAs (hsa-miR-10b-5p, hsa-miR-378a-3p and hsa-miR-4497) were positively correlated with HRP2 levels. 341

342

Six candidate miRNAs that were identified in the discovery phase were selected to determine the
validity of the previous results in an independent cohort of Mozambican children. The relative
expression of hsa-miR-3158-3p and hsa-miR-4497 was significantly higher in children with SM
compared to UM, with hsa-miR-3158-3p levels being higher in children with prostration, multiple
seizures as well as ARD, and hsa-miR-4497 in children with SA and ARD. To our knowledge, hsa-

19th Dec

miR-3158-3p, which is widely expressed in skin, spleen, kidney and brain tissues (37), has been 348 349 associated with bipolar disorders (38), but not with other infectious diseases. Further validation is required for hsa-miR-3158-3p, as the levels of this miRNA were found to be downregulated in the 350 plasma from Mozambican children recruited in 2006 with positive PM-agglutination compared to 351 no PM-agglutination, a Pf cytoadhesion phenotype which has been associated with malaria severity 352 (39). However, the positive correlation of hsa-miR-4497 with HRP2 levels, which was consistently 353 observed in the cohort of children from 2006 and 2014, suggesting that increasing parasite biomass 354 associated with parasite sequestration may lead to higher levels of secretion of this specific miRNA 355 by damaged tissues. hsa-miR-4497 is widely expressed in the lymph nodes, spleen, kidney and liver 356 357 tissues (37). Overall, this study shows that hsa-miR-4497, which is also associated with SM, might 358 be an interesting proxy marker of malaria severity. However, hsa-miR-4497 was found as a tumour suppressor (40), and associated with *Mycobacterium tuberculosis* infection (41). Therefore, 359 360 longitudinal studies are required to assess the prognostic value of this miRNA, as well as to estimate its differential expression in children with severity due to non-malarial infections. 361

362

Few of the most expressed miRNAs found in the present study, which represent a 70% of the total 363 miRNA counts in plasma samples, have been reported as highly abundant in plasma samples 364 365 previously (28, 42). According to public data deposited in the miRmine database (43), hsa-miR-486-5p and hsa-miR-451a are the two most abundant miRNAs in plasma and were also present in 366 the list of ten most expressed miRNAs of this study. Although there is no data available on 367 miRNAs from cell-conditioned media of HBE cells, miRNA data from other cell types, such as 368 primary tissue explants, primary stromal cells and breast cancer cell lines, also show low miRNA 369 vield (44), similar to this study. This observation indicates that RNA sequencing data obtained in 370 371 this study is of good quality and can be used for posterior analysis with high confidence. However, this study has several limitations. First, only HBE cells and ePCR-binding parasites were utilized 372

19th Dec

Gupta et al

for the *in vitro* assay, and therefore miRNAs produced by other parasite-host interactions 373 374 contributing to SM may have been missed. Second, plasma samples used in this study were collected retrospectively. Therefore, factors prior to small RNA sequencing and TaqMan-RT-375 gPCRs, such as time taken between centrifugation, storage, and storage temperature, might have 376 varied among the samples, affecting miRNA plasma levels (45, 46). However, confirmation of 377 findings in both the study cohorts suggest a minimal impact of pre-analytical conditions in the 378 379 results. Third, variations in the number of miRNAs identified in replicates of in vitro experiments may have led to the loss of some miRNAs. Fourth, the lack of tissue samples from organs with *Pf* 380 sequestration restricted the histological confirmation of identified miRNAs, and the presence of co-381 382 infections other than blood culture positive bacteraemia cannot be neglected in the studied plasma 383 samples. Finally, the association of each miRNA with specific symptoms that are part of the SM case definition may need further validation using a larger sample size, considering that our numbers 384 385 were relatively small for individual SM criteria. In addition, future studies using the machinelearning approaches would allow the identification of a combination of miRNAs that may detect 386 387 SM pathologies.

388

In conclusion, the profiling of miRNAs in media from HBE cells after incubation with a
cytoadherent *Pf* strain and in plasmas from Mozambican children with different clinical
presentations allowed the identification of promising miRNA candidates for characterizing severe
malaria, specifically hsa-miR-4497. This study opens the ground for future analyses to understand
the value of these miRNAs as a prognostic biomarker and for disentangling the aetiology of severe
malaria.

Biographical Sketch 423

424	•
-----	---

424	
425	Dr. Gupta is a molecular biologist and an early career malaria disease researcher. His research
426	focuses on host and parasite factors associated with severe malaria, and on the use of molecular
427	tools for the active surveillance of emerging drug resistance, gene deletions, and afebrile malaria in
428	malaria-endemic regions.
429	
430	Availability of data and materials
431	
432	The datasets analysed in this study are available from the corresponding author on request.
433	
434	Competing interests
435	
436	The authors declare that they have no competing interests.
437	
438	Authors' contributions
439	
440	HG, MR carried out the molecular analysis, results interpretation and wrote the first draft of this
441	manuscript. PC also carried out molecular analysis and conducted cytoadhesion assays. AS, RV,
442	LM and IC participated in fieldwork, collected clinical, epidemiological data, plasma samples, dried
443	blood drop filter papers and performed microscopy. AJ, XMV and DB participated in HRP2
444	analyse. MR, PC, HG, LP, AB and MB participated in bioinformatics and statistical analyses. QB
445	and AM participated in the study design, supervision, funding acquisition, project administration
446	and coordinated all the stages of the project. All authors reviewed and approved the final
447	manuscript.

724 Study population

725

Clinical malaria was defined as the presence of fever (axillary temperature≥37.5°C) with an asexual 726 parasitemia of $Pf > 500/\mu$ L. Children with severe malaria (SM) were those with at least one of the 727 following symptoms: cerebral malaria (Blantyre Coma Score ≤ 2), severe anaemia (SA, packed cell 728 volume <15% or haemoglobin <5g/dL), acidosis or acute respiratory distress (ARD, lactate >5mM 729 and/or chest in-drawing or deep breathing), prostration (inability to sit or breastfeed in children old 730 enough to do so based on their age), hypoglycaemia (blood glucose <2.2mM) and multiple seizures 731 $(\geq 2 \text{ convulsions in the preceding 24h})$ following the modified WHO criteria (1). Children with 732 uncomplicated malaria (UM) were those with clinical malaria but not presenting any 733 signs/symptoms of severity mentioned above (2). The presence of concomitant bacteraemia was 734 tested in all SM cases using blood cultures and children with positive bacteraemia were excluded. 735 736 Children with SM were treated according to Mozambican national guidelines with parenteral quinine in 2006 or parenteral artesunate (complemented with an oral artemisinin-based combination 737 738 therapy) in 2014, and those with UM were treated with a combination of oral amodiaguine and sulfadoxine-pyrimethamine (Fansidar®) in 2006 or with artemether-lumefantrine (Coartem®) in 739 2014. Ten ml of heparinized blood was collected from study participants and processed within 2 740 hours after collection. Filter paper dried blood spots of 60µL blood were prepared from the 741 vacutainer blood. After centrifugation at 1000rpms for 10minutes at 4°C, plasma was stored at -742 20°C. The 2014 study was conducted as a quasi-exact repetition of the 2006 study, the only 743

 $19^{th}\,Dec$

Gupta et al

- difference being that cases and controls were matched by parasitaemia level. Biochemistry
 parameters (glucose and lactate) and a full blood count were performed for each patient using
 Vitros DT60 and Sysmex Kx21 analyzers, respectively.
- 747

748 Parasitological determinations

749

750 Histidine-rich protein 2 (HRP2) levels were quantified using commercially available enzyme-linked immunosorbent assay kits (Malaria Ag CELISA; Cellabs Pty. Ltd., Brookvale, New South Wales, 751 Australia) and an in-house highly sensitive quantitative bead suspension array based on Luminex 752 753 technology. In brief, plasma samples were incubated overnight at 4°C with 2000 magnetic beads to 754 a final dilution of 1:10. After washing, beads were sequentially incubated with 100 µL of in-house biotinylated antibody α-HRP2 (MBS832975, MyBiSource, San Diego, CL) at 1 µg/ml and with 755 756 streptavidin-PE (42250-1ML, Sigma Aldrich, St. Louis, MO) at 1:1000 dilution. Finally, beads were washed and re-suspended in assay buffer, and the plate was read using the Luminex xMAP® 757 758 100/200 analyser (Luminex Corp., Austin, TX). A minimum of 50 microspheres per analyte were acquired and results were exported as crude median fluorescent intensity (MFI). Background 759 760 (blank) MFIs were subtracted and normalized to account for plate to plate variation. Ouantification 761 was performed against a 5-parameter logistic regression curve fitted from a calibration curve 762 consisting of recombinant protein HRP2 type A (890015, Microcoat GmbH, Germany). 763

764 Pf cytoadhesion assays

765

Human brain microvascular endothelial cells (Innoprot, Reference P10361) were cultured in 12
well-plates following the supplier's recommendations and were left until 40% confluency was
achieved. HBE cells were incubated in triplicate with *Pf*-iEs at trophozoite stage of the ePCR-

19th Dec

769	binding FCR3 strain (ePCR-iE; which expresses the PfEPM1 protein that binds to ePCR receptor)
770	and 3D7 strain (3D7-iE; a strain without the protein that binds to ePCR receptor) with 5% of both
771	parasitemia and haematocrit. Non-infected erythrocytes were used as negative control. The cell-
772	conditioned media of each group were collected after 1hr (t1) and 24hrs of stimulation (t24). Next
773	day, HBE cells were stimulated as described above, after 1-hour incubation in agitation, cells were
774	washed at least 10 times with binding media and fixed with 2% glutaraldehyde (SIGMA) in PBS
775	(Gibco) overnight to assess adhesion by light microscopy. After washing with water, cells were
776	stained with 10% Giemsa. iE and niE bound were counted in six different wells per assay in at least
777	500 nuclei cell per well. Results were presented as the number of adhered iE per 500 nuclei of cells.
778	Estimation of <i>Pf</i> adhesion to purified receptors (CD36, CD54 and g1CqR) as well as platelet-
779	mediated (PM)-agglutination and rosetting was performed as described elsewhere (2, 3).
780	Cytoadherence was defined as positive only if the number of iEs bound per mm ² was greater than
781	the mean binding plus 2 standard deviations to Duffy-Fc coated petri dishes. Pf isolates were
782	considered positive for PM clumping if the frequency of clumps was higher in the presence of
783	platelets than in buffer-control and for rosetting if the frequency of rosettes was higher than 2% (2,
784	4).

785

786 **Small RNA sequencing**

787

788 Before RNA extraction, the level of haemolysis in plasma samples was assessed by

789 spectrophotometry (EPOCH, BioTek) at a wavelength of 414nm (absorbance peak of free

- haemoglobin). Samples were classified as non-haemolysed if the optical density at 414nm was less 790
- than 0.2 (5). RNA was extracted from cell-conditioned media (3ml) and plasma samples (1ml) 791
- 792 using the miRNeasy tissues/cells kit and miRNeasy Plasma/Serum kit (Qiagen), respectively, with
- the use of 5µg UltraPure[™] glycogen/sample (Invitrogen). Given that the plasma samples were 793

19th Dec

794	conserved in heparin, RNA was precipitated with LiCl as described elsewhere (6). Purified RNA
795	quality and quantity were determined using the Bioanalyzer (Agilent Technologies) followed by
796	preparation of libraries using NEBNext® Small RNA Library Prep Set for Illumina® (New
797	England Biolabs), then separation of libraries in polyacrylamide gels (Novex, Invitrogen). The
798	Bioanalyzer was again used to quantify and assess the size of the libraries. Further, libraries were
799	pooled at the same equimolar concentrations and no more than 18 libraries were sequenced in the
800	same lane using a HiSeq 2000 (Illumina) platform following the protocol for small RNAs (7).
801	

A previously published pipeline was used to assess the sequencing quality, identification and 802 803 quantification of small RNAs and normalization (7). First, a quality control (QC) was conducted 804 using FASTX-Toolkit and FastQ Screen. After adaptor removing, reads with the following features were removed: 1) Reads <18nt, 2) Mean PHRED scores <30 and 3) Low complexity reads based on 805 806 the mean score of the read. Good quality reads were then annotated to main RNA categories (tRNA, 807 rRNA and miRNAs), and miRNA complexity was estimated as the number of distinct miRNAs that 808 were observed in each sample. Finally, contamination with RNA from other species was evaluated by mapping reads to clade-specific mature miRNA sequences extracted from miRBase v21 (8). The 809 810 tested species categories include animal sponges, nematodes, insects, lophotrochozoan, 811 echinoderms, fish, birds, reptiles, rodents and primates.

812

813 Sequences that passed the QC were subjected to the seqBuster/seqCluster tool that retrieves miRNA 814 and isomiRs counts (9, 10). To detect miRNAs and isomiRs, reads were mapped to the precursors 815 and annotated to miRNAs or isomiRs using miRBase version 21 with the miraligner (9). DESeq2 R 816 package v.1.10.1 (R version 3.3.2) (11) was used to perform an internal normalization where the 817 counts for a miRNA in each sample were divided by the median of the ratios of observed counts to

the geometric mean of each corresponding miRNAs over all samples.

19th Dec

Gupta et al

819

820 **Reverse transcriptase quantitative PCR**

821

Fifty ul of plasma from the Mozambican children recruited in 2014 with no haemolysis were used 822 for RNA extraction as described above. A synthetic RNA mimicking ath-miR-159a (Arabidopsis 823 thaliana; Metabion) was added after lysis reaction at a final concentration of 1.5pM, cDNA 824 825 synthesis and RT-qPCR [ABI PRISM 7500 HT Real-Time System (Applied Biosystems, Foster City, USA)] were performed using the TaqMan® Advanced miRNA assays. A standard curve of 826 five serially diluted points was prepared with cDNA of six randomly selected samples and was run 827 828 in triplicate for each miRNA. Results were normalized using a combination of endogenous controls 829 (ECs). The selection of ECs was based on the following criteria: a) reported in scientific literature as previously used as ECs (12, 13), b) coefficient of variance (CV) of normalized counts across all 830 831 samples $\leq 5\%$, c) basemean ≥ 3000 , d) standard deviation ≤ 1 and e) \log_2 fold change between SM and UM patients ≤ 1 . Finally, the best two ECs tested as housekeepings using the NormFinder (14) were 832 used for normalization of RT-qPCR data. miRNA relative expression levels (RELs) were calculated 833 with the $2^{-\Delta Ct}$ method, where $\Delta Ct = [Ct (miRNA) - Mean Ct (ECs)]$, considering efficiencies of 834 835 100% for all the miRNAs and ECs (12).

836

In silico analysis 837

- 838
- The selected miRNAs were screened through four different gene target prediction programs: 839
- DIANA-microT-CDS (15), MiRDIP (16), MirGate (17), and TargetScan 840
- (http://www.targetscan.org/vert 71/). Identified gene targets of each program were compared using 841
- an online tool Venny2.1.0 (http://bioinfogp.cnb.csic.es/tools/venny/). The gene targets that occurred 842
- in more than one database were selected and screened through the miRTarBase (18) online program 843

19th Dec

to check if these genes have been experimentally validated previously. These gene targets were
anticipated to be true positive targets present at detectable levels in field samples. The identified
gene targets were further analysed by DAVID 6.8 using *Homo sapiens* as the reference species.
Genes were clustered to Gene Ontology terms and KEGG pathways (fold enrichment >1.5 and p
<0.05).

849

850 Statistical analysis

851

Differential expression of miRNAs and isomiRs was assessed using DESEq2 and IsomiRs packages 852 853 in R (9, 10), which use negative binomial generalized linear models adjusted for multiple testing 854 with the false discovery rate (FDR) by the Benjamini-Hochberg method (19). Those with an FDR of 5% or below were selected for posterior analysis. Analysis of the modification in the bases of the 855 856 seed region was carried using isomiR package to determine a possible change in the target messenger RNAs. Mann-Whitney U and χ^2 (Chi-square) tests were performed to compare 857 858 continuous data and categorical data, respectively. Spearman correlation analysis was performed to assess the correlation of miRNA RELs (log transformed) with log transformed HRP2 levels. A two-859 sided p<0.05 was considered statistically significant. All statistical analyses were performed using 860 861 R 3.3.2 in Linux-based system and graphs were prepared with GraphPad. 862 863 864

865

918 Total number of miRNAs were 363 in RNA sequencing data;

919 baseMean = Mean normalized expression of the miRNAs in all the samples;

920 padj = adjusted for multiple testing by the Benjamini-Hochberg method;

921 3D7-iE, non-adherent 3D7-infected erythrocytes; ePCR-iE, adherent FCR3 expression endothelial receptor of protein C-infected erythrocytes

19th Dec

Table 4: Number of reads, quality control and number of different miRNAs detected in plasma 922

from Mozambican children recruited in 2006. 923
