7 Haven, CT, United States.

8

9 Abstract

10

11 Background: Testing recommendations for COVID-19 in the United States varied by
12 state and over time in the spring and summer of 2020.

13 Methods: We compiled data about COVID-19 testing, cases, and deaths, and excess
14 pneumonia + influenza + COVID-19 deaths to assess relationships between testing
15 recommendations, *per capita* tests performed, epidemic intensity, and excess mortality
16 during the early phase of the COVID-19 pandemic in the United States.

17 Results: As of July 2020, 16 states recommended testing asymptomatic members of the
18 general public. The rate of COVID-19 tests reported in each state correlates with more
19 inclusive testing recommendations and with higher epidemic intensity. Higher per capita
20 testing was associated with more complete reporting of COVID-19 deaths, which is a
21 fundamental requirement for analyzing the pandemic.

22 Conclusions: Reported deaths due to COVID-19 likely represent an undercount of the
23 true burden of the pandemic. Coordinated, consistent guidelines for COVID-19 testing
24 should be a high priority for state and national health systems.

25

26 Background

27

28 SARS-CoV-2, the virus that causes COVID-19, was declared a global pandemic by the
29 World Health Organization in March 2020.¹ Worldwide, responses to the pandemic have
30 varied and had varying success. In the United States, each state determined testing
31 guidelines, lockdown procedures, and reopening procedures individually.² The Centers
32 for Disease Control and Prevention also maintained testing recommendations and
33 guidelines, but states and localities were largely responsible for their own policies.³ The
34 COVID-19 pandemic in the United States is ongoing, costing around 150,000 lives by
35 the end of July 2020.⁴

36

37 Testing for COVID-19 has been a continual hurdle in the United States.⁵ Supply chain
38 issues,⁶ doubts about testing accuracy and methodology,⁷ and conflicting guidance from
39 federal, state and local officials about testing have all interfered with testing efforts.⁸
40 State governments and health departments established testing guidelines in March
41 2020, which were sometimes augmented by local governmental health departments.⁹
42 The turnaround time for test results has been strained,¹⁰ and resources for individuals to
43 sustain their household resources while remaining isolated or quarantined while
44 awaiting the result of a test have not been widely available.¹¹

45

46 Here we describe the changing recommendations for COVID-19 testing to the general
47 public in the United States in the spring and summer of 2020 and the consequences of
48 these changes for obtaining accurate statistics about the pandemic.

49

50 Methods

51

52 The objective of this analysis was to establish whether varying the state-level COVID-19
53 testing guidelines had any impact on the actual number of tests performed, and whether
54 the number of tests performed was related to the rate of recognizing COVID-19 deaths
55 as a cause of excess mortality (reported COVID-19 deaths/excess pneumonia +
56 influenza+ COVID-19 (PIC) deaths). COVID-19 testing guidelines were documented
57 from the websites of the departments of health in each of the 50 states and the District
58 of Columbia once monthly from March-July 2020 (Supplemental Table 1). We ranked
59 recommendations to tests by the general public (as opposed to members of specific
60 named risk groups) by assigning 0= criterion not specified, 1= accessible to people with
61 a negative influenza test, 2= accessible to people with symptoms consistent with
62 COVID-19 illness, 3= accessible to anyone, including asymptomatic people.

63

64 Correlations between testing recommendation score, tests per capita, and percentage
65 of positive tests were analyzed with Spearman correlation tests.

66

67 We used a generalized additive model (negative binomial link) to assess the
68 completeness of death reporting. The outcome variable was the number of reported
69 COVID-19 deaths in each state and month. The number of excess PIC deaths was
70 included as an offset term, so this effectively models the ratio of reported COVID-19
71 deaths/excess PIC deaths. The *per capita* testing rate in each state and month was
72 included as a penalized spline. Uncertainty in the estimates of excess PIC deaths were
73 ignored in these analyses, and excess PIC deaths were constrained to be greater than
74 or equal to the reported COVID-19 deaths. The model was fit using the package “mgcv”
75 in R.

76

77 We also evaluated relationships between the number of COVID-19 tests performed per
78 capita, testing recommendations score, and epidemic intensity (defined as excess PIC
79 deaths¹² per capita) using a negative binomial regression model. Total COVID-19 tests
80 performed in each state was the outcome variable, offset by the log of the total
81 population of each state, with the testing recommendations score (categorical) and the
82 log of epidemic intensity as the independent variables.

83

84 The number of excess PIC deaths per state and the reported number of COVID-19
85 deaths were obtained from a repository describing excess deaths during the COVID-19
86 outbreak (https://github.com/weinbergerlab/excess_pi_covid).¹² Final data were
87 obtained August 15, 2020. Positive tests and the overall number of tests in each state
88 were collected from the website of The COVID Tracking Project
89 (<https://covidtracking.com/>). Population data were taken from the United States Census

90 Bureau's 2019 estimates. R (R: A language and environment for statistical computing,
91 version 3.6.1. R Foundation for Statistical Computing, Vienna, Austria, [https://www.R-](https://www.R-project.org/)
92 [project.org/.](https://www.R-project.org/)) was used for statistical analyses.

93

94 Results

95

96 *State Testing Guidelines*

97 From March to July 2020, recommendations of COVID-19 testing for the general public
98 varied between states and over time (Figure 1), as did testing prioritization for identified
99 risk groups (Supplemental Figure 1).

100

101 The earliest-available state-level data ranged from March 1 (in Michigan, Rhode Island,
102 and Washington) to March 12 (in Massachusetts), while the remaining 47 states began
103 reporting COVID-19 data between March 4 and March 7. March data included all March
104 dates – April 4; April data included April 5 – May 2; May data included May 3 – June 6;
105 June data included June 7 – July 4; July data included records from July 5 – 31.

106

107 As of July, 16 states recommended that asymptomatic members of the general public
108 be tested for COVID-19. 9 states actively recommended against the testing of
109 asymptomatic people; 3 of which then reversed this recommendation in July. South
110 Dakota also recommended against seeking a test if people were experiencing
111 symptoms, citing the lack of effective COVID-19 therapy as a contraindication for
112 testing. Most states (35/51) changed their testing recommendations twice between

113 March and July. Only Oklahoma did not change their testing criteria, though the state
114 health department website specifies that private testing facilities have their own criteria.

115

116 *Factors associated with higher rates of testing*

117 Reported COVID-19 tests *per capita* increased steadily, though unevenly, from March to
118 June, while the percentage of positive tests varied widely between states (Figure 2, 3).

119 States with more permissive testing recommendations had a lower percentage of
120 positive tests (rho -0.22, 95% CI -0.34, -0.11), reflecting the inclusion of lower risk
121 individuals in the testing pool. The minimum percentage of positive tests for a single
122 month was 0.8% in May in Alaska; the maximum was 47% in April in New Jersey. In a
123 multivariate model, both more inclusive testing recommendations and higher epidemic
124 intensity were associated with higher rates of testing.

125

126 *Testing intensity and completeness of death reporting*

127 The completeness of recording deaths as due to COVID-19 was related to the rate of
128 testing. (Figure 4). This was particularly true in the first months of the
129 pandemic when testing levels were low relative to the intensity of the epidemic; in later
130 months, the level of testing was high and had little influence on the difference between
131 reported COVID-19 deaths and excess PIC deaths.

132

133 Discussion

134

135 In order to obtain accurate statistics on the COVID-19 pandemic, viral testing needs to
136 scale with epidemic intensity. Particularly in the early months of the pandemic,
137 restrictive state-level testing recommendations and difficulties in accessing tests
138 resulted in inadequate testing levels.⁵ This was manifest in higher viral positivity rates
139 and greater differences between reported COVID-19 deaths and excess PIC deaths.
140 From March-May, testing per capita and completeness of mortality data both increased,
141 though afterwards this apparent relationship became less clear. It is possible that other
142 characteristics of healthcare systems in each state influenced both the testing rates and
143 completeness of death reporting (i.e. supply chain or personnel issues). The variation in
144 data completeness seen in July may be due to reporting delays, and thus might
145 decrease as mortality data are updated. Expanded access to testing can play a critical
146 role in obtaining an accurate picture of the progression of the epidemic.

147

148 This study has certain limitations. Changes in completeness of death reporting could be
149 influenced by other factors that might also vary over time, such as state-level guidelines
150 for coding deaths as due to COVID-19. The viral testing criteria established by state
151 health departments are sometimes superseded by local governments or private clinics.⁹
152 The testing data counts tests, not individuals, so people tested multiple times will be
153 included multiple times.

154

155 Conclusions

156

157 The patchwork of state-level testing guidelines is associated with local variations in
158 testing intensity, and these variations have consequences for the completeness of data
159 on key indicators of the severity and progression of the pandemic. More coordinated
160 national guidance could strengthen the pandemic tracking and response.

161

165 CI: confidence interval

166

167 Declarations

168

169 **Ethics approval and consent to participate:** Not applicable

170 **Consent for publication:** Not applicable

171 **Availability of data and materials:** The datasets generated and/or analysed during the
172 current study are available in the COVID Tracking Project repository
173 (<https://covidtracking.com/>), the excess PIC mortality repository
174 (https://github.com/weinbergerlab/excess_pi_covid), and on the websites of the state
175 health departments (all of which appear in Supplemental Table 1).

176 **Competing interests:** SRP has received travel fees from Pfizer unrelated to this
177 manuscript. DMW has received consulting fees from Pfizer, Merck, GSK, and Affinivax
178 for work unrelated to this manuscript and is Principal Investigator on a grant from Pfizer
179 to Yale University on a project unrelated to this manuscript

180 **Funding:** SP was supported by a NIH T32 training grant, award number
181 2T32AI007210-36A1 (MPI).

182 **Authors' contributions:** SP conceived of the study, extracted the data, ran the
183 analyses, and wrote the first draft of the paper. DMW contributed to the design of the
184 study and revisions of the manuscript and plotting.

185 **Acknowledgements:** We would like to thank the state health departments in the United
186 States and the District of Columbia and the COVID Tracking Project for providing data
187 used for these analyses.

188 **Authors' information:** stephanie.perniciaro@yale.edu

Figure 2. COVID-19 tests per 1000 population in the United States (A), and the percentage of positive COVID-19 tests (B), March-July 2020. Each state has a line; colors of lines are determined by geographic region per the inserted map.

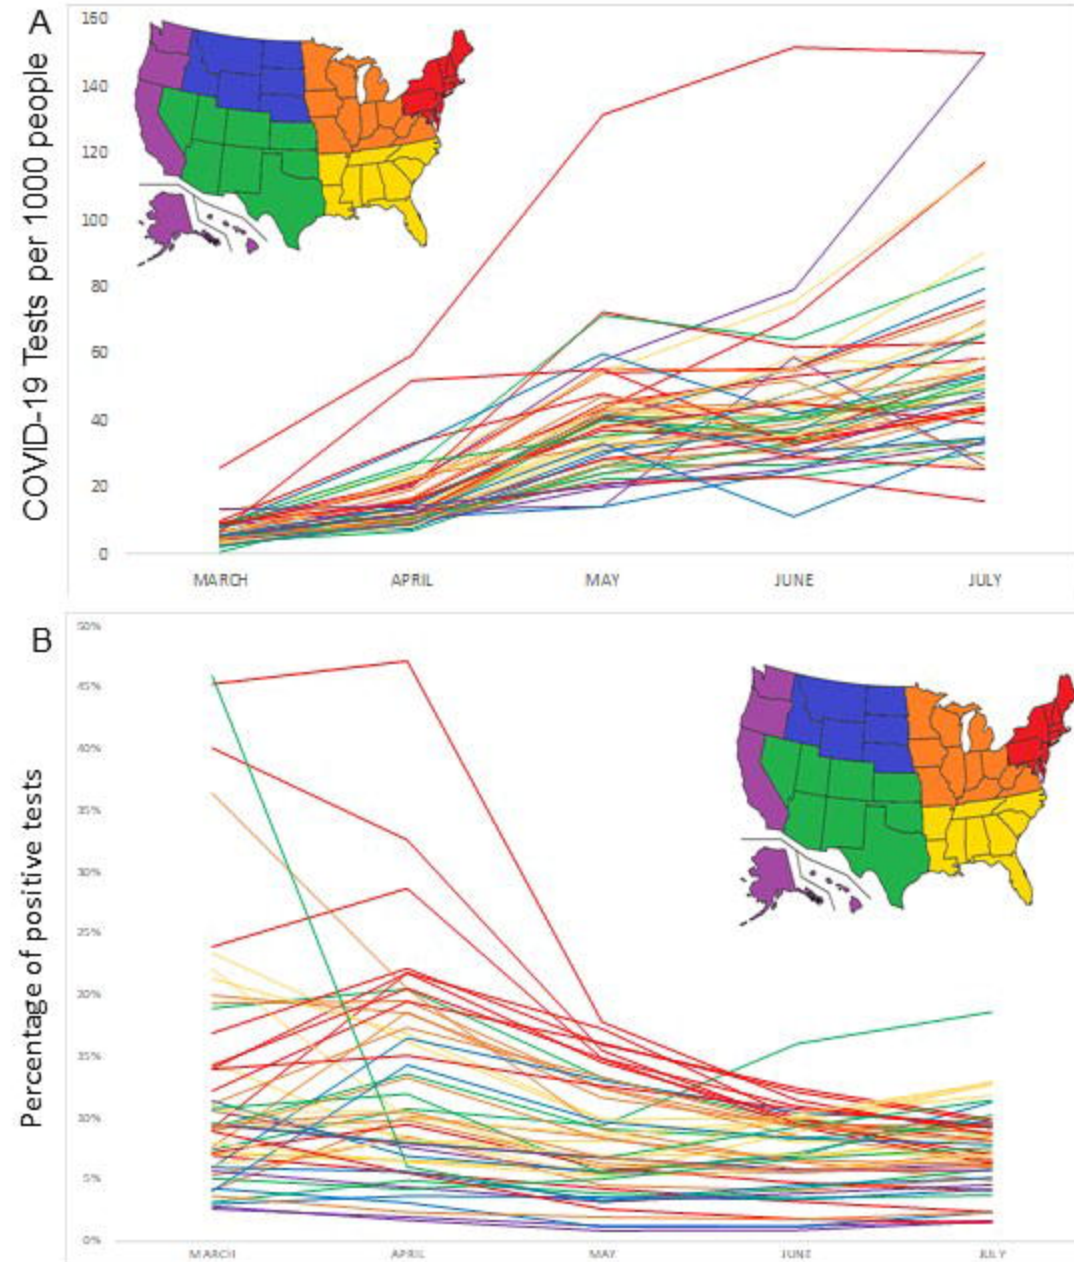

Figure 3. COVID-19 testing recommendation scores (A) and COVID-19 tests per 1000 people (B) from March-July, 2020 in the United States

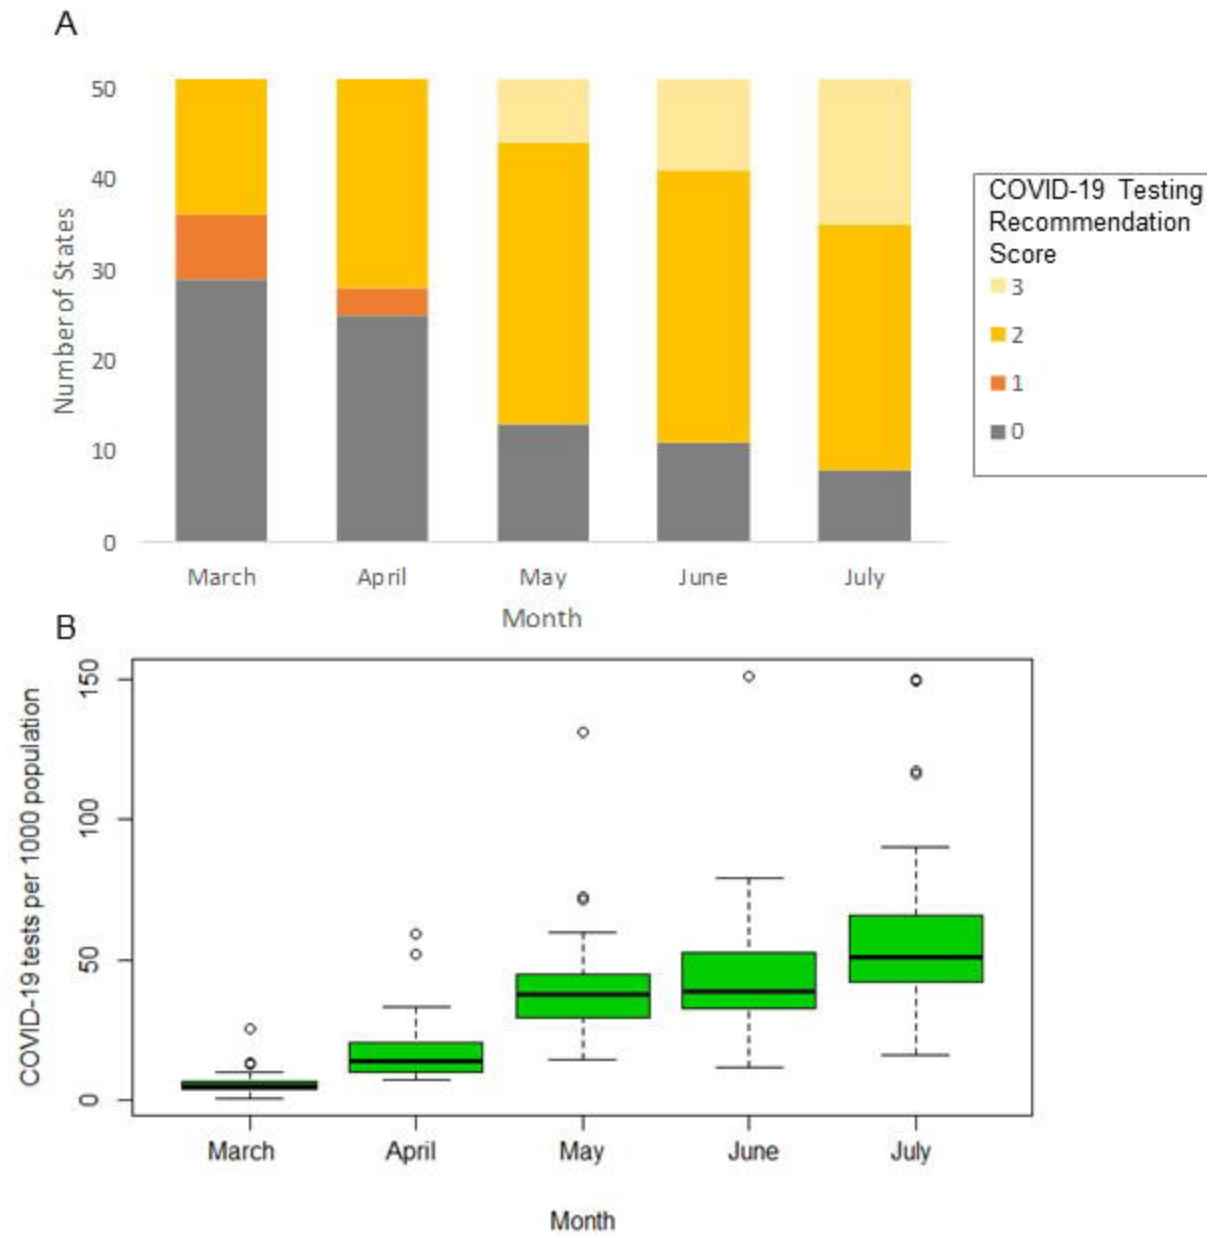

Figure 4. Association between the rate of testing for SARS-CoV-2 (*per capita*) and the completeness of death reporting, as measured by the ratio between reported COVID-19 deaths and excess deaths due to pneumonia/influenza/coronavirus (PIC). The line +/- 95% confidence intervals represents the trend as estimated from a generalized additive model. The size of the circles is proportional to the number of excess deaths due to PIC in each state. The color depicts the month (March-July)—earlier months are darker colors, later months are lighter.
