23 **ABSTRACT**

24 **Objectives:** Near-source tracking of SARS-CoV-2 RNA in the sewage drains serving
25 particular buildings may allow rapid identification of SARS-CoV-2 infection cases or
26 local outbreaks. In this pilot study, we investigated whether this was the case for
27 nursing homes (NH).

28 **Methods:** The study involved five NH (from A to E) affiliated to the Clínico-
29 Malvarrosa Health Department, Valencia (Spain). These were nursing or mixed
30 nursing/care homes of different sizes, altogether providing care for 472 residents
31 attended by a staff of 309. Near-source sewage samples were screened for presence of
32 SARS-CoV-2 RNA by RT-qPCR at least 5 days per week during the study period.
33 SARS-CoV-2 RNA testing in nasopharyngeal swabs from residents and staff was
34 performed with the TaqPath COVID-19 Combo Kit (Thermo Fisher Scientific,
35 Massachusetts, USA).

36 **Results:** SARS-CoV-2 RNA was detected in wastewater samples from four of the five
37 NH. SARS-CoV-2 infection cases were documented in three of these four NH. Of the
38 two NH without SARS-CoV-2 infection cases, no SARS-CoV-2 RNA was detected in
39 sewer samples from one facility, while it was repeatedly detected in samples from the
40 other. Presence of SARS-CoV-2 RNA in sewage preceded identification of isolated
41 cases among residents or staff or outbreak declaration in two NH, with lag times
42 ranging from 5 to 19 days.

43 **Conclusion:** Our study demonstrated that intermittent or persistent detection of SARS-
44 CoV-2 RNA in NH sewers can provide an early warning of subsequent individual cases
45 or outbreaks in these facilities.

46 **KEYWORDS:** SARS-CoV-2 RNA, Nursing homes, wastewater, near-source tracking,
47 COVID-19 outbreak.

48 **INTRODUCTION**

49 Nursing homes (NH) have been severely affected by the COVID-19 pandemic, largely
50 due to their congregate nature and the vulnerability of residents [1,2]. Advanced age,
51 frailty and concurrence of underlying chronic health conditions place NH residents at
52 high risk for developing severe forms of COVID-19 and death. In Spain, at least 50% of
53 NH-resident deaths officially reported by the Ministry of Health have been directly or
54 indirectly attributed to COVID-19. Early detection of SARS-CoV-2 outbreaks at NH
55 through periodic and systematic RT-PCR screening of residents and personnel has been
56 invoked as a seemingly effective strategy to rapidly blunt virus spread in this setting
57 [3,4]. Routine implementation of this approach has encountered many logistical
58 obstacles, however, and to our knowledge its cost-effectiveness has not been
59 incontrovertibly proven. Long-lasting virus shedding of SARS-CoV-2 in urine and feces
60 has been documented in both symptomatic and asymptomatic infected adults [5]. As a
61 result, near-source tracking in the sewers serving particular buildings has emerged as an
62 appealing non-invasive tool which when combined with subsequent targeted population
63 screening when SARS-CoV-2 is detected may enable rapid identification and control of
64 facility outbreaks [6,7].

65 In this pilot study, we provide evidence demonstrating the feasibility and utility of this
66 wastewater-based epidemiological approach for early identification of isolated cases or
67 outbreaks of SARS-CoV-2 infection in NH.

68 **MATERIAL AND METHODS**

69 **Nursing homes and sewage sampling**

70 This pilot study involved five NH (listed as A to E) facilities located in Northeast
71 Valencia (Spain), affiliated to the Clínico-Malvarrosa Health Department. These were
72 nursing or mixed nursing/care homes of different sizes (Table 1), altogether providing
73 care for 472 residents attended by 309 staff. Selection from among the 17 NH supported
74 by the Clínico-Malvarrosa Health Department was based upon two criteria: (i) existence
75 of sewage drain(s) not shared with nearby buildings and (ii) personal autonomy of most
76 residents. NH sewage drain(s) were monitored for presence of SARS-CoV-2 RNA by
77 testing near-source wastewater samples at least 5 days per week from October 7 to
78 December 28, 2020. All except one NH (NHE) had a single drain site. Grab samples
79 were collected on site from water outlets at each facility. At NHE, hierarchical pooling
80 involved testing a combination of multiple samples from different sampling sites.
81 Positive pool samples were deconvoluted and individually tested. All samples were
82 taken early in the morning, collecting 1 L of water in sterile plastic containers with
83 sodium thiosulfate (VWR, USA). Water samples were transferred to the laboratory,
84 refrigerated at 4 °C and concentrated within 24 h.

85 **SARS-CoV-2 detection and quantitation in sewage samples**

86 Sewage water samples were analyzed at Global Omnium laboratory. Samples were
87 concentrated using the aluminum adsorption-precipitation method [8,9]. A final
88 concentrate was then obtained by centrifugation at $1,900 \times g$ for 30 min; the resulting
89 pellet was resuspended in 1 mL of PBS, pH 7.4. Viral extraction from wastewater
90 concentrates was carried out using the NucleoSpin RNA virus Kit (MACHEREY-
91 NAGEL, Germany). SARS-CoV-2 RNA detection was performed by RT-qPCR using
92 One Step PrimeScript™ RT-PCR Kit (Perfect Real Time) (Takara Bio, USA), targeting
93 the nucleoprotein (N), N1 and N2 fragments [10], and envelope protein (E) gene [11].
94 RNA samples were analyzed in duplicate. Each RT-qPCR run included negative

95 (nuclease-free water) and positive controls. RT-qPCR targets were quantified by
96 plotting the quantification cycles (C_T) to an external standard curve built with 10-fold
97 serial dilution of the 2019-nCoV_N_Positive Control and 2019-nCoV_E_Positive
98 Control (IDT). Mengovirus RNA recovery rates were calculated and used as quality
99 assurance parameters according to ISO 15216-1:2017 [12]. Results are reported as
100 genome copies (GC)/L.

101 **SARS-CoV-2 testing in residents and staff**

102 Nasopharyngeal swabs (NP) for RT-PCR testing were collected by experienced nurses
103 at the NH sites and immediately placed in 3 ml of Universal Transport Medium (UTM,
104 Becton Dickinson, Sparks, MD, USA). RT-qPCRs were conducted within 24 h of
105 specimen collection at the Microbiology Service of Hospital Clínico Universitario
106 (Valencia, Spain) with the TaqPath COVID-19 Combo Kit (Thermo Fisher Scientific,
107 Massachusetts, USA) [13]. RNA was extracted using the Applied Biosystems™
108 MagMAX™ Viral/Pathogen II Nucleic Acid Isolation Kits coupled with Thermo
109 Scientific™ KingFisher Flex automated instrument (Thermo Fisher Scientific).

110 **Ethics statement**

111 Permission to analyze the wastewater was granted by the nursing home operator and
112 local authority responsible for the sewer system. Ethical approval for this study was
113 waived by the Hospital Clínico Universitario INCLIVA Ethics Committee because RT-
114 PCR testing either for diagnosis purposes or surveillance of both nursing home residents
115 and staff are usual practices at health Department Clínico-Malvarrosa, Valencia, Spain.

116 **RESULTS**

117 SARS-CoV-2 RNA was detected in wastewater samples collected from four out of the
118 five NH. The dynamics of SARS-CoV-2 RNA detection and viral loads measured at

119 each NH are shown in Figure 1. SARS-CoV-2 infection cases, either asymptomatic or
120 symptomatic, were documented in three of the four NH (Table 1). No cases were
121 identified at NHD within the study period, despite repeated detection of SARS-CoV-2
122 RNA in the sewage drain. Of note, residents and staff at NHD were screened by RT-
123 PCR on October 29, twelve days after SARS-CoV-2 was first detected in sewage, all
124 yielding negative results. SARS-CoV-2 RNA was not detected in samples collected
125 from NHC and no cases were documented throughout the follow-up period. The
126 timespan between first SARS-CoV-2 RNA detection in sewage and index case
127 diagnosis at each NH is shown in Table 1 (and depicted in Figure 1). Presence of
128 SARS-CoV-2 RNA in sewage preceded identification of isolated cases among residents
129 or staff (in both cases symptomatic) or outbreak declaration in two NH (NHA at during
130 two different time periods, and NHB). Repeated detection of SARS-CoV-2 RNA was
131 not documented until after outbreak declaration in the case of NHE (Table 1), although
132 it should be noted that between October 7 and first case detection on October 17 only
133 two of the four sewage drains at NHE had been sampled.

134 SARS-CoV-2 RNA levels in wastewater samples increased exponentially over the
135 course of NH outbreaks (NHA and NHE), reaching peak levels above 8.0 log₁₀ GC/L
136 (Figure 1).

137 Finally, disappearance of SARS-CoV-2 RNA from sewers was associated with control
138 of outbreaks or absence of new case documentation following implementation of
139 adequate measures (isolation of positive case and quarantining of close contacts)
140 (Figure 1). The SARS-CoV-2 outbreak at NHA is currently still active.

141 **DISCUSSION**

142 Wastewater SARS-CoV-2 RT-PCR testing has emerged as an efficient strategy for
143 epidemiological surveillance of COVID-19, as traces of SARS-CoV-2 RNA frequently
144 predate detection of cases in the community by between 4 and 15 days [8,14-16].
145 Likewise, tracking SARS-CoV-2 in sewer systems from different facilities (i.e. campus
146 dorms, workplaces, correctional facilities, schools) may allow early documentation of
147 SARS-CoV-2 circulation, thus potentially contributing to prompt blunting of viral
148 transmission [6,7]. Results from this study suggested that SARS-CoV-2 RNA
149 surveillance of sewage drains may indeed serve as an early warning system for isolated
150 cases or outbreak declaration of SARS-CoV-2 infection in NH. This was found to be the
151 case in NHA and NHB with lag times ranging from 5 to 19 days, and although
152 speculative, could also have been the case in NHE, had we not missed two out of the
153 four sewage drains at NH. Of analogous importance was the fact that SARS-CoV-2
154 RNA traces were not detected in NHC, the facility in which no cases were reported
155 within the study period.

156 An intriguing observation was that repeated detection (at 8 time points) of SARS-CoV-
157 2 in NHD sewers was neither preceded nor followed by case detection in this facility.
158 Furthermore, all residents and staff at NHD were screened by RT-PCR as part of this
159 pilot experiment a few days after first SARS-CoV-2 RNA detection in sewage, all
160 returning negative results. Although a plausible explanation for this was that
161 precautionary measures to avoid virus transmission were maximized following first
162 detection of SARS-CoV-2 RNA in this particular facility, and that any infected
163 resident/s or staff member/s may have yielded false-negative RT-PCR results [17], a
164 thorough investigation conducted after systematic screening of NHD population
165 revealed the existence of cross-contamination between sewage drains of this NH and
166 that of an adjacent building, that had gone unnoticed.

167 On the other hand, as expected, SARS-CoV-2 RNA levels in sewage drains increased
168 dramatically during outbreak periods.

169 The main limitation of the current study is the relatively limited number of NH recruited
170 for the study.

171 In conclusion, this pilot study proved that intermittent or persistent detection of SARS-
172 CoV-2 RNA in NH sewage drains often anticipates declaration of individual cases or
173 outbreaks. Frequent SARS-CoV-2 RT-qPCR sewage testing coupled with targeted
174 screening of residents and staff may prove useful for early blunting of virus
175 transmission and spread at NH. Further studies with a larger site sample are warranted
176 to confirm this assumption.

177 **ACKNOWLEDGMENTS**
