21

22

23 **ABSTRACT**

24 **Context:** During the fall of 2020, some high schools across the US allowed their students to
25 participate in interscholastic sports while others cancelled or postponed their sport programs
26 due to concerns regarding CoVID19 transmission. It is unknown what effect this has had on the
27 physical and mental health of student athletes.

28 **Objective:** Identify the impact of playing a sport during the CoVID19 pandemic on the health of
29 student athletes.

30 **Design:** Cross-sectional study.

31 **Setting:** Sample recruited via email.

32 **Patients or Other Participants:** 559 Wisconsin high school athletes (age=15.7±1.2 yrs.,
33 female=44%) from 44 high schools completed an online survey in October 2020. A total
34 of 171 (31%) athletes played (PLY) a fall sport, while 388 (69%) did not play (DNP).

35 **Main Outcome Measure(s):** Demographics included: sex, grade and sports played.
36 Assessments included the General Anxiety Disorder-7 Item (GAD-7) for anxiety, Patient Health
37 Questionnaire-9 Item (PHQ-9) for depression, the Pediatric Functional Activity Brief Scale
38 (PFABS) for physical activity, and the Pediatric Quality of Life Inventory 4.0 (PedsQL) for quality
39 of life. Univariable comparisons between the two groups were made via t-tests or chi-square
40 tests. Means for each continuous outcome measure were compared between the groups by
41 ANOVA models that controlled for Age, Sex, Teaching method (Virtual, Hybrid, or In-person),
42 and the % of students eligible for free lunch.

43 **RESULTS:** PLY group participants were less likely to report moderate to severe symptoms of
44 anxiety (PLY=6.6%, DNP=44.1%, $p < 0.001$) and depression (PLY=18.2%, DNP=40.4%,
45 $p < 0.001$). PLY athletes reported higher (better) PFABS scores (mean: [95%CI]),
46 (PLY=23.2[22.0,24.5], DNP=16.4[15.0,17.8], $p < 0.001$) and higher (better) PedsQL total scores
47 (PLY=88.4[85.9,90.9], DNP=79.6[76.8,82.4], $p < 0.001$).

48 **CONCLUSIONS:** Adolescent athletes who played a sport during the CoVID19 pandemic
49 reported fewer symptoms of anxiety and depression, as well as higher physical activity and
50 quality of life scores compared to adolescent athletes who did not play a sport.

51

52 **Key words:** Public health, CoVID-19, Youth, Depression

53 **Abstract word count:** 300

54 **Manuscript word count:** 3931

55

56 **Key points:**

57 **1)** High school students who played a sport during the CoVID-19 pandemic in the fall of
58 2020 were less likely to report anxiety and depression symptoms than athletes who did
59 not play a sport.

60 **2)** High school students who played a sport during the CoVID-19 pandemic in the fall of
61 2020 reported higher physical activity and quality of life scores compared to high school
62 athletes who did not play a sport.

63 **3)** Participation in high school sports may have significant physical and mental health
64 benefits for US adolescent athletes during the CoVID-19 pandemic.

65

66

67 INTRODUCTION

68 An estimated 8.4 million US high school students participate in interscholastic athletics
69 each year.¹ Adolescent sport participation is recognized to have profound positive influences on
70 the health and well-being of adolescent students as evidenced by higher academic
71 achievement, greater levels of physical activity and decreased levels of anxiety and depression
72 compared to students who do not participate in athletics.²⁻⁶ Additionally, research has shown
73 that high school sport participation is one of the most important factors for life-long physical
74 activity and health.⁷⁻¹²

75 During the spring of 2020, CoVID-19, the disease caused by the novel SARS-CoV-2
76 coronavirus, reached pandemic levels in the US. Schools were closed and high school sports
77 were cancelled to slow the spread of the disease. Experts have suggested that while necessary
78 to slow the community spread of the virus, the CoVID-19 mitigation strategies may nonetheless
79 have profound mental and physical health consequences for students.¹³⁻¹⁸ For example, experts
80 have indicated that the CoVID-19 pandemic will make it more likely that youth will engage in
81 sedentary activities and increase the prevalence of childhood obesity.¹⁹⁻²³

82 Research has also shown that females, older athletes, team sport participants and
83 athletes from areas with higher levels of poverty reported more symptoms of anxiety and
84 depression, as well as lower levels of physical activity and health related quality of life (HRQoL)
85 in May 2020 during the widespread shutdown.²⁴ Another study reported that adolescent
86 athletes in May 2020 reported more mental health symptoms, as well as lower physical activity
87 and HRQoL scores compared to similar samples of adolescent athletes prior to the CoVID-19
88 pandemic.²⁵

89 During summer 2020, school districts across the US made determinations regarding
90 whether to allow interscholastic sports to resume based on input from various health and sport
91 associations while recognizing that various sports would possibly pose varying risks for the
92 transmission of CoVID-19 depending on the nature of the sport.²⁶⁻²⁸ During fall 2020, fourteen

93 states in the US (27%) allowed full fall sport participation, and 30 states (60%) allowed modified
94 sport participation, with the remaining 6 states and the District of Columbia (13%) not allowing
95 any interscholastic athletic participation.²⁹ In addition, within each state that allowed full or
96 modified participation, individual school districts were allowed to determine which sports they
97 offered. Some schools allowed all their fall sports, while other districts sponsored a portion of
98 their sports while postponing or cancelling other sports.²⁹

99 A drawback to the recent studies regarding the impact of CoVID-19 on the health of
100 adolescent athletes is the difficulty discerning if the health changes reported were primarily due
101 to restrictions on sport participation or due to other factors such as the lack of in-person school
102 attendance, the increased economic uncertainty or concerns about contracting the SARS-CoV-2
103 coronavirus. There is a need, therefore, to determine if sport participation independently affects
104 the health of adolescent athletes during the CoVID-19 pandemic.

105 We are not aware of research to date that has specifically documented how sport
106 participation during the CoVID-19 pandemic affects the mental and physical health of
107 adolescent athletes. This information may assist sports medicine providers, school
108 administrators and health care policy experts with implementing strategies to improve the short-
109 term and long-term mental and physical health of adolescent athletes in the months and years
110 to come as we transition from the CoVID-19 pandemic.^{30,31} Therefore, the purpose of this study
111 was to measure the impact of sport participation on the mental and physical health of
112 adolescent athletes during the CoVID-19 pandemic. To measure this impact, we compared
113 self-report data on anxiety, depression, physical activity and HRQoL for a cohort of athletes who
114 played a sport with a similar cohort of athletes who did not play a sport in Wisconsin during fall
115 2020. We hypothesize that adolescent student athletes who played a sport will report
116 significantly better mental health, physical activity and HRQoL than athletes who did not play a
117 sport.

118

119 **METHODS**

120 This study was approved by the University of Wisconsin Health Sciences Institutional Review
121 Board in September 2020.

122 Wisconsin allowed individual school districts to determine whether to sponsor
123 interscholastic teams during the fall of 2020.³² The traditional fall sports (prior to the CoVID-19
124 pandemic) offered in Wisconsin high schools included cross country, football, volleyball (boys
125 and girls), golf (girls), swim (boys and girls), tennis (girls), and soccer (boys). Approximately
126 305 (60%) of the 510 schools opted to sponsor teams for all fall sports, while 104 (20%) opted
127 to offer a limited number of sports, and the remaining 101 (20%) offered no fall sports at their
128 schools.

129 The sports offered most often by schools included boys' and girls' cross country (78%)
130 and girls' golf (72%). The sports offered least often included football (54%), boys' soccer (50%)
131 and girls' swimming (50%).³³

132 Wisconsin high school athletes (male and female, grade: 9–12, age: 13-19) were
133 recruited to participate in the study by completing an anonymous online survey in October 2020.
134 Emails were sent to athletic trainers and coaches from 44 schools to solicit their athletes to
135 participate in the study. The survey included 69 items and included a section to solicit
136 demographic information, followed by 3 validated instruments used to measure physical activity,
137 mental health and HRQoL in adolescents. Demographic responses regarding the participant's
138 age, grade and school name, as well as any high school sport in which they competed during
139 the fall and planned to compete in if the sport was offered by the school during the winter and
140 spring of the 2020/21 school year were collected. The remainder of the survey consisted of an
141 assessment of mental health, physical activity level and HRQoL.

142 **Mental health**

143 The General Anxiety Disorder-7 Item (GAD-7) and Patient Health Questionnaire-9 Item
144 (PHQ-9) surveys were used to evaluate anxiety and depression symptoms,

145 respectively.³⁴ The questionnaires ask participants to rate the frequency of anxiety or
146 depression symptoms experienced in the past two weeks. The GAD-7 scale is a valid,
147 reliable and sensitive measure of anxiety symptoms and is able to differentiate between
148 mild and moderate GAD in adolescents.³⁵ Scores range from 0-21 with a higher score
149 indicating increased anxiety. In addition to the total score, GAD-7 categorical scores of 0–
150 4, 5-9, 10–14, and 15–21 correspond to no, mild, moderate, and severe anxiety
151 symptoms, respectively.³⁶ The PHQ-9 is a 9-item screening questionnaire for depression
152 symptoms with scores ranging from 0-27 with a higher score indicating a greater level of
153 depression. The PHQ-9 has demonstrated high sensitivity and specificity for depression
154 screening in adolescent patients aged 13 to 17 years.³⁷ In addition to the total score,
155 PHQ-9 categorical scores of 0–4, 5–9, 10–14, 15–19 and ≥ 20 correspond to minimal or
156 none, mild, moderate, moderately severe and severe depression symptoms,
157 respectively.³⁸

158 **Physical Activity**

159 Physical activity level was assessed with the Hospital for Special Surgery Pediatric
160 Functional Activity Brief Scale (PFABS). This validated 8-item instrument was designed to
161 measure the activity of active children between 10 and 18 years old for the past month.
162 Scores range from 0 to 30 with a higher score indicating greater physical activity.^{39,40}

163 **Health Related Quality of Life**

164 HRQoL was measured with Pediatric Quality of Life Inventory 4.0 (PedsQL). The 23-item
165 PedsQL questionnaire assesses HRQoL for the previous 7 days. A physical summary score
166 (physical function) and psychosocial (a combination of emotional, social and school function)
167 summary score, as well as the total PedsQL scores can be calculated, with scores ranging from
168 0 to 100 and a higher score indicating greater HRQoL. The PedsQL has been validated for use
169 in children ages 2 to 18.^{41,42}

170 **Statistical analyses**

171 Statistical analyses were performed for participants who provided a valid, complete survey.
172 Participants were excluded if they did not complete the entire survey, were not in grades 9 -12,
173 or indicated they did not plan to play interscholastic sports at their school. Participants'
174 demographic variables were summarized (mean [SD] or N [%]) overall and by study participants
175 for sex and fall sport participation. Participants were classified as playing a fall sport (PLY) or
176 as not playing a fall sport (DNP).

177 The characteristics for the schools attended by the participants included the type of
178 instructional delivery method and the % of students eligible for free or reduced lunch. The type
179 of instructional delivery method (online only, in person or hybrid [a combination of in person and
180 online]) was determined by reviewing information on each school's website. The % of the
181 students eligible for free or reduced lunch for each school was obtained from the publicly
182 available data available online through the Wisconsin Department of Public Instruction.⁴³

183 Means (mean, [95%CI]) for each continuous outcome measure were reported and
184 compared between fall sport participation groups by ANOVA models that controlled for age, sex,
185 type of teaching method and % of students who were eligible for free or reduced lunch. Ordinal
186 logistic regression models were used to estimate the percentages of level of depression (PHQ-
187 9) and anxiety (GAD-7) by group. These models controlled for the same covariates listed
188 above. All tests had a 0.05 significance level. Analyses were conducted in R for statistical
189 computing version 3.5.

190

191 **RESULTS**

192 A total of 559 high school athletes (age = 15.7±1.2 yrs., female = 43.6%, male = 56.4%)
193 completed the survey. Due to the convenience sampling design, information regarding the
194 response rate was unavailable. Three hundred eighty-eight (69.4%) participants reported they
195 did not play (DNP) an interscholastic sport at their school, while 171 (30.6%) reported they did
196 play (PLY) an interscholastic sport. The majority (n = 257, 66.2%) of the participants in the

197 DNP group attended schools that cancelled all fall sports, and 91.4% (n = 355) attended
198 schools that delivered all instruction online. The % of students eligible for free or reduced lunch
199 (mean \pm SD) for the schools was $25.9 \pm 10.3\%$. One hundred forty-eight (86.5%) of the
200 participants in the PLY group attended schools that offered all fall sports, with 40.3% (n = 69)
201 attending school in-person. Participants in the PLY group were most likely to report playing
202 volleyball (n = 66, 38.6%), football (n = 53, 31%) and boys' soccer (n = 22, 12.9%). Participants
203 in the DNP group most commonly reported that they had intended to play football (n = 160,
204 41.2%), and volleyball (n = 51, 13.1%). Seventy nine participants (20.4%) did not play a fall
205 sport but intended to play a high school winter or spring sport. A summary of the participant
206 characteristics is found in Table 1.

207 **Mental Health**

208 The PLY participants were more likely to report GAD-7 symptom scores of 0 to 4, indicating no
209 or minimal anxiety (PLY = 80.1% vs DNP = 26.4%), whereas the DNP athletes were more likely
210 to report scores of 10 to 21, indicating more moderate to severe anxiety than the PLY group
211 (DNP = 44.1% vs PLY = 6.6%) as shown in Figure 1. The PLY participants were more likely to
212 report PHQ-9 scores 0 to 4, indicating no or minimal depression (PLY = 57.7% vs DNP =
213 31.3%), whereas the DNP athletes were more likely to report scores of 10 to 27, indicating more
214 moderate to severe depression than the PLY group (DNP = 40.1% vs PLY = 18.2%) as shown
215 in Figure 2. The DNP group reported a higher (worse) GAD-7 score (mean, [95%CI]) than the
216 PLY group (8.4 [7.2, 9.5] vs. 3.2 [2.2, 4.3], < 0.001) as well as a higher (worse) PHQ-9 score
217 than the PLY group (7.6 [6.4, 8.8] vs. 3.9 [2.8, 4.9], < 0.001). The total GAD-7 and PHQ-9
218 scores for both groups are found in Table 2.

219 **Physical Activity and HRQoL**

220 Physical activity, as measured by PFABS scores (mean, [95%CI]) for the PLY group were 41%
221 higher (better) than the DNP group (PLY = 23.2 [22.0, 24.5] vs. DNP = 16.4 [15.0, 17.8], p <
222 0.001). The PFABS scores for both groups are found in Table 2. The HRQoL for athletes in the

223 PLY group was higher (better) than the DNP athletes. Specifically, the PedsQL physical health
224 summary scores for the PLY group were higher than the DNP group (PLY = 92.3 [90.1, 94.4] vs.
225 DNP = 86.5 [84.1, 88.9], $p = 0.004$), as was the psychosocial health summary score (PLY =
226 86.4 [83.3, 89.4] vs. DNP = 75.9 [72.5, 79.3], $p < 0.001$) and the total PedsQL score (PLY =
227 88.4 [85.9, 90.9] vs. DNP = 79.6 [76.8, 82.4], $p < 0.001$). The PedsQL scores for both the PLY
228 and DNP groups are found in Table 2.

229

230 **DISCUSSION**

231 To our knowledge, this is the first study to compare the mental health status, physical activity
232 level and HRQoL between high school athletes who were or were not able to participate in
233 interscholastic sports during the CoVID-19 pandemic. This study builds on prior research
234 demonstrating the dramatic changes in physical and mental health following the cancellation of
235 high school sports in the spring of 2020.^{24,25} A limitation of the prior studies is the difficulty
236 discerning if the health changes reported were primarily due to the restrictions on sport
237 participation or the result of other factors such as sex, age, socioeconomic status or the lack of
238 in-person school attendance. After controlling for grade, sex, school instructional delivery
239 method and the % of students qualifying for free and reduced lunch, our findings demonstrate
240 that athletes who did not play interscholastic sports experienced significantly worse symptoms
241 of anxiety and depression, lower levels of physical activity and worse HRQoL compared to
242 athletes who did not play sports in fall 2020. This suggests that the re-initiation of sport
243 participation may result in significant improvements in mental and physical health for
244 adolescents during the CoVID-19 pandemic.

245

246 **Mental Health**

247 Athletes that played high school sports in the fall of 2020 demonstrated significantly lower
248 symptoms of anxiety and depression than those athletes who did not play a sport. Specifically,

249 athletes in the DNP group were more than 6 times as likely to report moderate to severe
250 symptoms of anxiety and more than twice as likely to report moderate to severe symptoms of
251 depression even after adjusting for age, sex, type of school instruction and % of the students
252 qualifying for free and reduced lunch. This seems to suggest that while PLY athletes continue
253 to demonstrate slightly higher levels of depression and anxiety than historical values, the mental
254 health burden among DNP athletes is considerably worse.²⁵ In fact, the DNP group
255 demonstrates levels of moderate to severe anxiety and depression symptoms similar to those
256 identified in a nationwide sample for adolescent athletes in May 2020 (anxiety = 36.7%,
257 depression = 27.1%).²⁵ Given the adolescent mental health crisis that existed prior to the onset
258 of CoVID-19, and the known mental health benefits of sport participation, this data seems to
259 suggest that adolescent athletes who are unable to return to sports may be at a significantly
260 greater risk for mental health issues.

261 Experts have pointed out that the CoVID-19 pandemic has negatively impacted the
262 mental health of youth and may be related to decreased socialization, increased family strain,
263 and reduced access to support services.^{13,44} As such, we recognize that factors beyond sport
264 participation such as the ability to attend school in-person may contribute to adolescent mental
265 health. In addition, depression and anxiety in adolescent athletes have been shown to be
266 related to sex and grade in school. Nonetheless, after controlling for the type of school
267 instructional delivery (online, in-person or hybrid), age and sex, sport participation remained
268 significantly associated with large improvements in anxiety and depression symptoms.
269 Therefore, we can reasonably assume that the increased symptoms we identified among the
270 DNP participants are at least partly attributable to the lack of sport participation.

271 Our results also support previous research that has demonstrated that sport participation
272 improves the mental health of youth and adolescents.⁴⁵⁻⁴⁸ A recent study during the early stages
273 of the CoVID-19 pandemic found that 11.4% of student athletes who were unable to participate
274 in sports reported moderate to severe levels of depression symptoms, which was four times

275 higher than the rate (2.8%) reported by student athletes prior to the CoVID-19 pandemic.²⁵ This
276 supports the premise that sport participation may represent an important mechanism to improve
277 the mental health of adolescents as society continues to attempt to mitigate the impact of
278 CoVID-19 in the months and years to come.

279 **Physical Activity**

280 Our study demonstrates that during the CoVID-19 pandemic, high school athletes who
281 played high school sports had a significantly higher level of physical activity than athletes who
282 did not play a sport. Notably, the total PFABS score for the PLY group was similar to scores
283 (mean, [95%CI]) for healthy high school aged athletes prior to CoVID-19 (24.7 [24.5,24.9]).²⁵
284 Similarly, the PFABS scores for the PLY group were similar to scores for adolescents reported
285 by Donovan (23.8 ± 5.3) as well as to normative data reported by Fabricant (20.2 ± 7.2).^{40,49}
286 Further, the PFABS scores for the PLY group were nearly twice as high as those reported by
287 high school athletes unable to play any sports in May 2020 (12.1 [11.7, 12.5]). Finally, the DNP
288 group reported scores that were 25% and 45% lower than scores reported by Fabricant and
289 Donovan, respectively.^{40,49} This may indicate that by being able to play a sport, these athletes
290 mitigated, to some degree, the low level of physical activity reported during the initial onset of
291 the CoVID-19 pandemic.

292 Physical activity is known to have a beneficial effect on a wide range of health outcomes
293 in adolescents, including sleep, academic success, well-being, and mental health.^{5,6,9,12,45-48,50}
294 Therefore, it is possible that the identified decrease in mental health in the DNP group may be
295 at least partly due to the removal of the positive effects that physical activity has for
296 adolescents. In addition, childhood obesity was a public health crisis before CoVID-19, and is
297 projected to become worse due to the pandemic.^{19,21,51} Decreased physical activity in
298 adolescents may also have long-term negative effects and implications in terms of increased
299 risk for obesity and cardiometabolic disease if these levels remain low for prolonged periods.⁵²
300 Chronically low levels of physical activity may also compound the mental health consequences

301 of the current crisis and increase the risk^{46,50} Returning high school sport opportunities is a
302 complex issue and requires careful consideration. Stakeholders should consider the promotion
303 of physical activity for adolescents a top priority during the CoVID-19 pandemic.

304 **Health Related Quality of Life**

305 HRQoL is a measurement of well-being, and well-being has been associated with self-perceived
306 health, longevity, and healthy behaviors.⁵³ We found that adolescent athletes who had returned
307 to sport in fall 2020 reported significantly higher HRQoL than those athletes unable to return to
308 sport. This is consistent with prior studies that have shown that individuals with increased
309 physical activity and/or interscholastic sport participation report higher HRQoL scores compared
310 to inactive adolescents and high school non-athletes.⁵⁴⁻⁵⁷ Therefore, it is not surprising that
311 HRQoL scores for the PLY athletes were higher than the DNP athletes.

312 The total PedsQL scores reported here for the PLY athletes are significantly higher than
313 scores (mean [95%CI]) reported by high school athletes when sports were cancelled (76.7,
314 [76,0, 77.5]).²⁴ Further, the total PedsQL scores reported by the PLY athletes are similar to
315 scores (mean \pm SD) recorded in 14 to 18 year-old athletes prior to the pandemic by Lam (89.4 \pm
316 9.6 to 90.5 \pm 10.2), Snyder (89.5 \pm 10.1 to 93.6 \pm 7.6) and McGuine (90.9 [90.5,91.3])^{25,55,56} The
317 increased scores for the PLY group may also be attributed to aspects of sport participation
318 beyond the opportunity for structured physical activity such as goal setting, emotional support
319 and social interaction with teammates. This may suggest that by playing a sport, adolescents
320 may be able to return to a “normal” or “expected” level of HRQoL similar to those recorded prior
321 to the CoVID-19 pandemic.

322 On the other hand, the total PedsQL scores for the DNP athletes were lower than
323 reported Peds QL scores in non-athletes (84.7 \pm 12.7 to 85.8 \pm 11.4) reported by Lam et. al.⁵⁶
324 Interestingly, the DNP scores are similar to scores reported in populations of youth age 5 – 18
325 with chronic conditions such as asthma (74.8 \pm 16.5), cardiac disease (77.4 \pm 14.5) and
326 diabetes (80.3 + 12.9) reported by Varni.⁵⁸ The reduced HRQoL in the DNP group may be due

327 in part to the decreased physical activity levels we noted previously. Since HRQoL is
328 multifactorial, however, the scores reported by the DNP group are also likely impacted by other
329 aspects of the lack of sport participation such as the continued loss of social interaction and loss
330 of identity. Nonetheless, this difference persisted after controlling for school instructional
331 delivery type, grade, sex, as well as the % of students eligible for free and reduced lunch,
332 suggesting that the differences we noted may be attributable to the lack of sport participation
333 itself. Further, the fact that the PLY group reported HRQoL similar to data collected prior to the
334 pandemic may indicate that providing sport opportunities can positively impact multiple
335 dimensions of adolescent health. Moving forward, validated health and well-being
336 measurements provide a common metric for future studies to compare their results with our
337 reported data.⁵³ These metrics may help policy makers with future decisions that may affect the
338 health and well-being of student athletes in the coming months and years as we transition
339 beyond the immediate impacts of the CoVID-19 pandemic.⁵⁹⁻⁶¹

340

341 **Limitations**

342 This study has several limitations. First, the data provided were self-reported from online
343 surveys and not the result of a clinical examination conducted by a health care provider.
344 However, our findings are consistent with reports from experts and US Centers for Disease
345 Control who have stated that CoVID-19 will impact the mental and physical health of
346 youth.^{13,14,62} Second, we acknowledge that there may be a response bias for participants. We
347 cannot know for certain if the sample is representative of all the athletes at the schools or
348 biased towards athletes who were more likely to respond if they experienced the most profound
349 impacts on their health. Third, due to the survey delivery method, our sample may be biased
350 towards athletes from higher socioeconomic groups with easy access to internet services.
351 Fourth, we used the % of students eligible for free and reduced lunch for each school as a
352 measure of economic status for individual respondents. However, we felt that this would be

353 more accurate as a measure of economic status rather than asking students to accurately report
354 their household income. Finally, we recognize that mental health and overall well-being are
355 complex and are potentially affected by other factors for which we were not able to account in
356 our study and which could confound the results. Specifically, we did not ask the respondents
357 whether they had any fears of contracting the CoVID-19 virus. Nonetheless, we were able to
358 control for sex, age, and school instruction and the % of kids eligible for free or reduced lunch to
359 help better define the impacts of sport participation during CoVID-19.

360

361 **CONCLUSION**

362 In this study, we found that adolescent athletes who were able to return to sport participation in
363 fall 2020 reported dramatically lower symptoms of anxiety and depression, higher physical
364 activity levels and higher HRQoL, even after adjusting for grade, sex, and the type of school
365 instructional delivery. As we continue through the CoVID-19 pandemic, it is our hope that this
366 information will help inform public health experts, school administrators, and sports medicine
367 and mental health providers regarding the potential physical and mental health benefits
368 associated with the participation in organized sports for adolescents. We recognize that
369 returning to organized sports is a complex issue and requires careful consideration.

370 Nonetheless, research continues to suggest that sport participation during the CoVID-19
371 pandemic is associated with significant mental and physical health benefits in adolescents.
