9 **ABSTRACT**

10 **Background:** Riding a bike is beneficial for health, the environment and for reducing traffic congestion. Despite this, bike
11 riding participation in the state of Victoria, Australia, is low. To inform planning and practice, there is a need to understand
12 the proportion of the population (the ‘near-market’) that are interested in riding a bike, and how this varies across regions.
13 The Geller typology classifies individuals into one of four groups, based on their confidence to ride a bike in various
14 infrastructure types, and frequency of bike riding. The typology has been used at a city, state and country-wide scale,
15 however not at a smaller spatial scale. We aimed to characterise and quantify the distribution of the Geller typology within
16 Local Government Areas (LGAs) in the state of Victoria, Australia.

17 **Methods:** An online survey was conducted in 37 LGAs in Victoria, including all LGAs in Greater Melbourne, and a selection of
18 six key regional centres. Participants were recruited from an opt-in online research company panel with the objective of
19 recruiting a representative sample of adults across each LGA. The Geller typology classified individuals as either: ‘Strong and
20 Fearless’, ‘Enthusied and Confident’, ‘Interested but Concerned’, or ‘No Way No How’. ‘Interested but Concerned’
21 participants are those that would ride a bike if protected infrastructure were provided.

22 **Results:** The survey was completed by 3999 individuals. Most participants owned a bike (58%), however only 20% rode at
23 least once per week. The distribution of the Geller groups was: ‘Strong and Fearless’ (3%), ‘Enthusied and Confident’ (3%),
24 ‘Interested but Concerned’ (78%), and ‘No Way No How’ (16%). While variation in the distributions of the Geller groups was
25 observed between LGAs within Greater Melbourne., the ‘Interested but Concerned’ group, reflecting people who are
26 comfortable riding only in protected lanes or off-road paths, was high across all LGAs and all demographic sub-groups. Even
27 though the frequency of riding a bike was lower in women, interest in riding a bike was high and comparable to men.
28 Participants who resided in the outer urban fringe regions of Greater Melbourne had high interest, but low participation in
29 bike riding.

30 **Conclusions:** While there was variation in interest in bike riding across an entire metropolitan region and across population
31 groups, interest was high across all areas and demographics. Our results show the potential for substantial increases in
32 cycling participation, but only when high-quality cycling infrastructure is provided. Further research is required to
33 understand the policy and practice barriers to equitable provision of protected infrastructure.

34

35 INTRODUCTION

36 Increasing participation in bike riding is well established as being beneficial for public health, the
37 environment and traffic congestion (1-5). The majority of populated areas of Australia exhibit ideal
38 conditions for riding a bicycle, including relatively flat topography and in most areas, a mild climate. Despite
39 this, participation in bike riding remains low in Australia compared to other international settings (6). To
40 increase bike riding participation and to ensure that planning and practice efforts are targeted to the whole
41 community, there is a need to identify specific sub-groups of the population that can be classified as the
42 bike riding 'near-market'; individuals who would like to start riding a bike. Bike rider typologies are
43 commonly used to achieve this, by segmenting populations into distinct groups with shared characteristics.

44 The most commonly used bicyclist typology is the 'Four Types of Cyclist' typology, first introduced in 2006
45 by Roger Geller (7) and later refined by Dill & McNeil (8). This classifies people into one of four groups
46 based on their confidence to ride a bike in various infrastructure types, their interest in riding a bike and if
47 they had ridden a bike in the past month. One of the four categories are people who are 'Interested but
48 Concerned'. Interested but Concerned participants are those that would ride a bike if protected
49 infrastructure were provided. The typology has been used to quantify potentially latent groups of bicyclists
50 in cities, states, and countries. While the use of typologies to quantify the near-market of bicyclists across
51 large cities and regions has been helpful in informing bike riding strategies, prior studies have not explored
52 whether interest in bike riding varies within these geographies, such as across smaller spatial areas of cities
53 and states (8-11). The availability and quality of transport infrastructure often varies within cities
54 depending on zoning, distance from the city, topography, socioeconomic status and community
55 demographics (12-14). Identifying interest in bike riding at this small spatial scale is useful in understanding
56 geographical variation in bike riding potential and how protected infrastructure can be implemented to
57 maximise bike riding participation and address inequities in participation and infrastructure. To our
58 knowledge, previous literature has not quantified the Geller typology groups at a spatial scale smaller than
59 cities, and has not been applied in Australia.

60 In this study, we aimed to quantify and identify the characteristics of the ‘Four Types of Cyclist’ in all Local
61 Government Areas (LGAs) within Greater Melbourne, and a selection of regional centres in the state of
62 Victoria, Australia.

63 **METHODS**

64 **Study design**

65 We conducted a cross-sectional online survey in the state of Victoria, Australia. The objective was to recruit
66 a representative sample of adults (aged 18 years and older) across each local government area. Data
67 collection occurred over the period of August 12th to September 10th, 2020. Data collection occurred during
68 a period of restrictions due to the COVID-19 pandemic. Many Victorian workplaces were closed and
69 physical distancing was enforced (15), but there were no restrictions placed on leaving the home during
70 this period.

71 In line with values-based messaging for health promotion (16), we adopted the term “bike riding” rather
72 than “cycling”, and their equivalents, in this study to ensure inclusivity and avoid association with
73 competitive cycling (17).

74 **Setting**

75 Victoria has a population of 6.7 million (18) of which 67% reside in the Greater Melbourne area (19). As of
76 2018, bike riding comprised 3% of all weekday trips in metropolitan Melbourne (20). LGAs were chosen as
77 the geographical area for analysis. LGAs in Australia are defined subdivisions of states that are under the
78 jurisdiction of a particular Local Government (21). In Victoria, 85% of the road network is made up of local
79 roads, which are maintained by Local Governments (22). For this reason, Local Governments play an
80 essential role in the planning and maintenance of bicycling infrastructure. Data were collected in each LGA
81 within Greater Melbourne (n=31) and select regional LGAs (n=6) (**Error! Reference source not found.**).

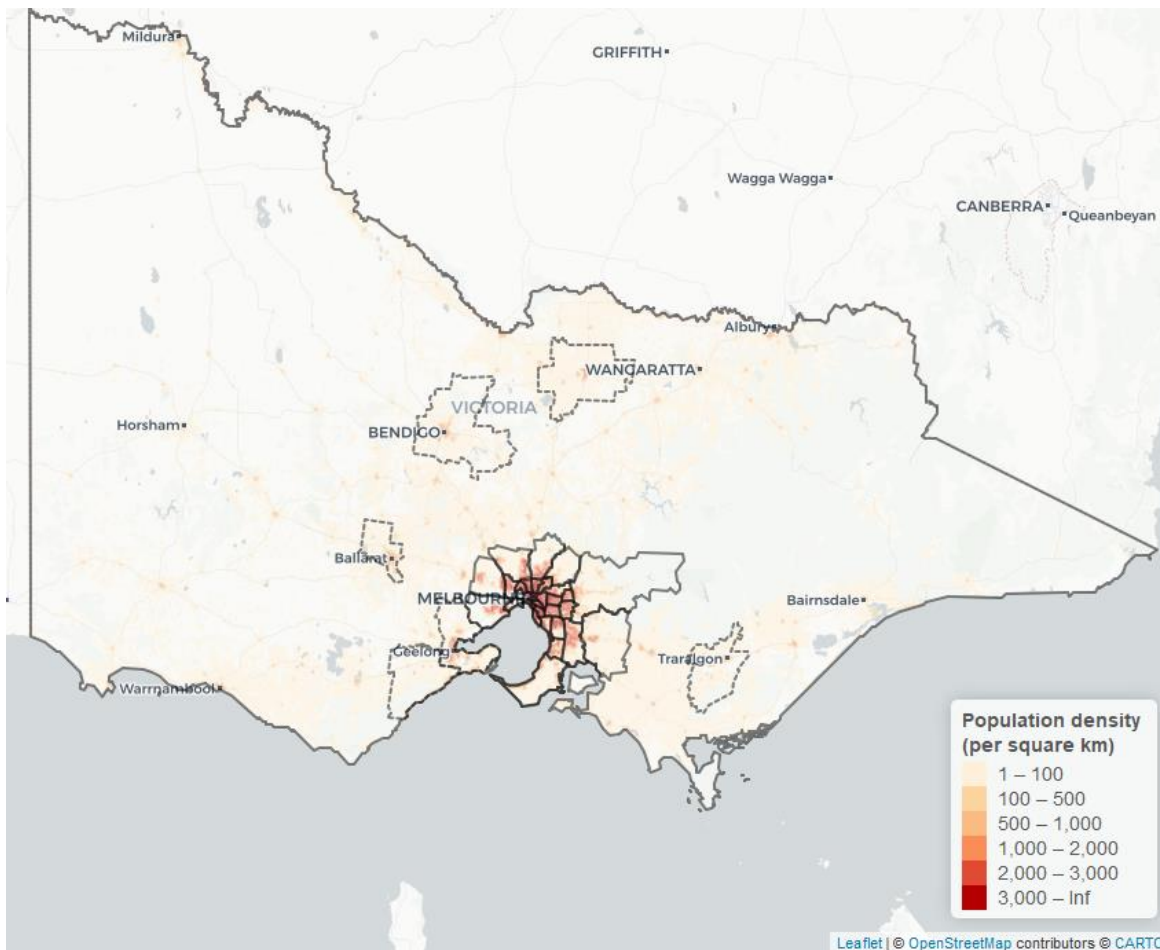

Figure 1. Map of included LGAs and population density within the state of Victoria (Regional LGAs = dotted border, Greater Melbourne LGAs = solid border)

Greater Melbourne LGAs were chosen specifically due to the high density of population (see Figure 1, Figure 2), and potential to improve bike riding participation rates and infrastructure. Similarly, data were collected in six regional centres with higher populations, higher population density and relatively flat topography. These areas also had the potential for increased participation in bike riding. Achieving a representative sample in rural/regional LGAs other than those selected was not feasible due to small survey panel sizes in these regions.

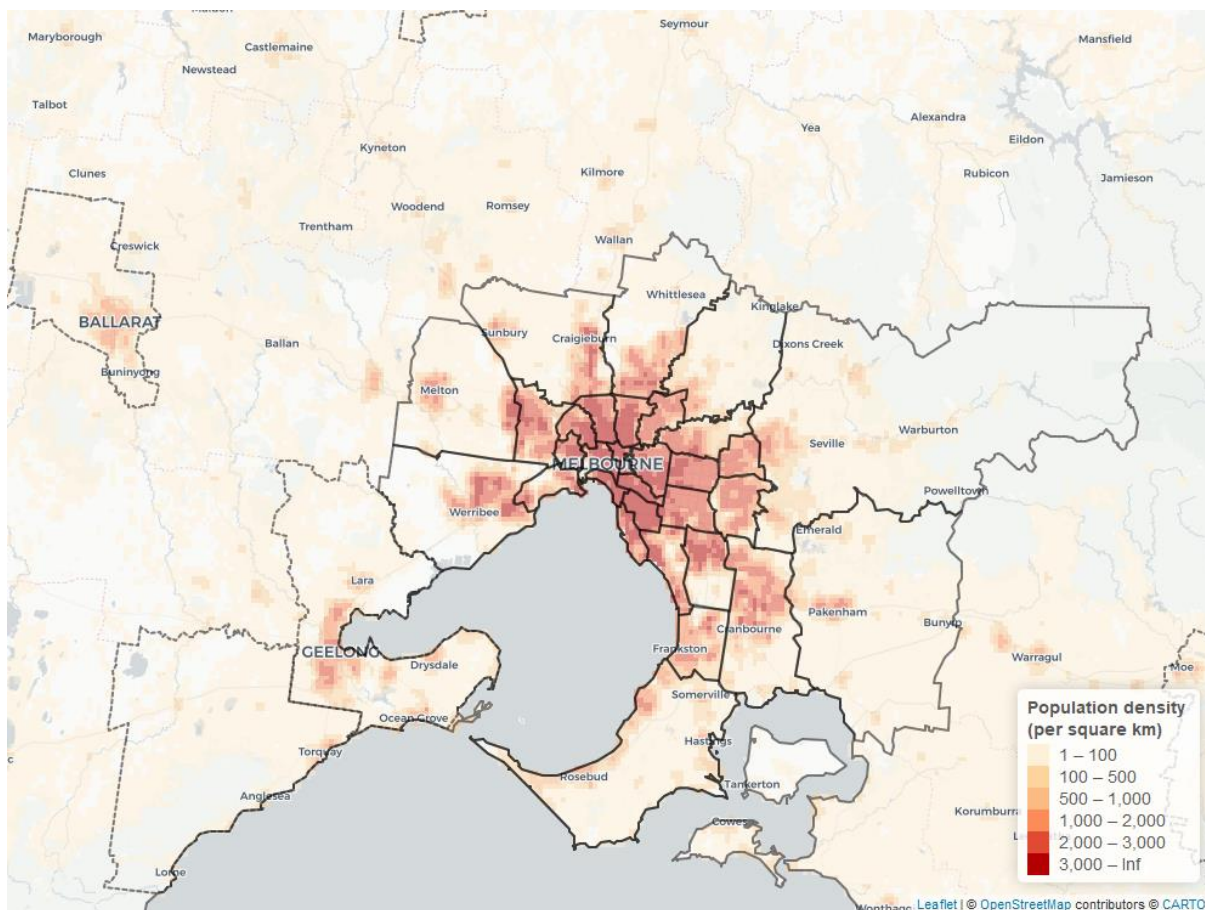

Figure 2. Map of population density in Greater Melbourne (Greater Melbourne LGAs = solid line, Regional LGAs = dotted line)

Survey design

A cross-sectional online survey was developed by the study authors, and administered through Qualtrics Survey Software (23). The full survey is provided as Supplementary Material A. The survey included questions about demographics, bike riding frequency and behaviours, and a set of questions to categorise participants into one of the four Geller cycling topologies (7, 8). The Geller typology uses descriptions and illustrations of a variety of street environments, levels of bike riding infrastructure and traffic speeds and asks participants how comfortable they would be riding a bike in those conditions on a 4-point Likert scale, from 1 = “Very uncomfortable” to 4 = “Very comfortable”. Participants are also asked their level of agreement with the statement “I would like to cycle more”, with a 4-point Likert scale from 1 = “Strongly disagree” to 4 = “Strongly agree”. The answers to these scenarios distinguish which of the four bike riding typologies the participant belongs to. Groups consist of people who are “Strong and Fearless”, “Enthusied and Confident”, “Interested but Concerned” or “No Way No How”. Strong and Fearless participants are

105 comfortable riding a bike on any infrastructure, including on roads with no protected bicycling
106 infrastructure. Enthusied and Confident participants are comfortable on non-residential streets with painted
107 on-road bike lanes (separating bikes from traffic without protection). Interested but Concerned participants
108 are comfortable riding a bike on protected bicycling infrastructure only, while No Way No How participants
109 are not comfortable riding a bike in any setting.

110 Adaptations were made to the Geller Typology for use in Australia. These included the conversion of miles
111 per hour to kilometres per hour, and change of the term “striped bike lane” to “painted bike lane”. Each
112 question included a figure to allow the participant to better understand the scenario and context (see
113 Figure 3). Photos were not used as to avoid associations with particular areas, or other factors that could
114 influence bike riding comfort. The Geller typology was chosen for this study for its ability to inform policy
115 and practice, and to allow for comparisons to studies in other settings that have used the same questions.
116 Questions regarding frequency of bike riding and trip purpose were asked from the perspective of before
117 COVID-19 restrictions were in place (see Supplementary Material).

118

119 *Figure 3. Example image alongside Geller Typology questions - Question 3: “How comfortable would you feel riding a bike on a two-*
120 *lane commercial shopping street with traffic speeds of 30-40 km/h, on-street parking and a painted bike-lane?” Image developed by*
121 *the authors.*

Demographic data included age category (18-24 years, 25-34 years, 35-44 years, 45-64 years, 65-74 years, 75 and above years), gender (female, male, non-binary, other (contents specified by participant)), individual gross annual income from 2019 in \$AUD (\$1-\$10,399, \$10,400-\$20,799, \$20,800-\$31,199, \$31,200-\$41,599, \$41,600-\$51,999, \$52,000-\$64,999, \$65,000-\$77,999, \$78,000-\$103,999 and \$104,000 or more), whether the person spoke a language other than English at home, and Victorian postcode of residence. Postcodes do not form part of the Australian Statistical Geography Standard (24) and do not necessarily uniquely fit within a single LGA. Therefore, where a participant resided in a postcode bounded across multiple LGAs ($n=79$ postcodes), they were directed to a map of their postcode with LGAs boundaries and asked to select the LGA they resided in.

Sampling and recruitment

We recruited people 18 years of age or older who resided in one of the LGAs in Greater Melbourne or one of the six regional LGAs. The aim was to achieve a representative sample size within each LGA, so that typologies between LGAs could be compared. Sample size was calculated for each of the LGAs based on the 2016 Australian Bureau of Statistics Census 2016 data (25) and using a 95% confidence level and a 2% margin of error, totalling $n = 3351$. The survey was distributed online via email to a sample obtained from a market research company, The Online Research Unit (ORU). The ORU panels are built using a variety of recruitment methods to ensure adequate general population representation and reduce selection bias: through post, phone, print and online. Invitations were sent in batches from Monday to Friday, with more invitations being sent on Friday to take account of the longer time period over the weekend where no email invitations were sent. By sending the invitations in batches, this reduced bias towards early responders and minimised response bias by distributing responses over different days. Participants who had partially responded to the survey or not entered the survey were sent a maximum of two reminders over the data collection period to reduce non-response bias. In order to monitor the Victorian population sample representativeness, the ORU were sent daily reports for the age and gender distributions for the completed survey sample to date. Where particular groups were lower than the population, 'boosting' was performed by sending further invitations and reminders those demographics not meeting the required

148 proportions for sample representativeness. Age and gender representation at the LGA level was not
149 possible to monitor due to restrictions on information sharing restrictions between the ORU and Monash
150 University. Oversampling was performed for small LGA sub-populations to allow for more reliable estimates
151 and to avoid sampling bias due to under-coverage. When sample sizes were achieved, no further invitations
152 were sent to participants that resided in these areas.

153 **Statistical analysis**

154 Responses were checked for duplicates, of which none were found. Completion times were checked for
155 outliers to identify any responses completed in a time that was not feasible, and removed if so. Further
156 cleaning of potentially straight-lined responses was not possible as these responses may have been valid.
157 Results for the overall sample were weighted to reflect the correct population representation of each LGA
158 to account for oversampling in any of the LGAs and to remove any sampling bias. Statistical analysis was
159 performed in the statistical program R and the integrated development environment RStudio (26) using the
160 *survey* library for analysis of weighted data (27). Survey demographic data were compared to the aggregate
161 population data for each of the included LGAs from the 2016 Census (25), with the exception of data
162 relating to speaking a language other than English at home. This was not available for the selected LGA
163 populations, and instead was obtained from a separate report and based on the whole of the Victorian
164 population (28). Maps of population density (Figure 1 and Figure 2) were produced based on Australian
165 Bureau of Statistics population density data (29), using the *leaflet* package in R (26, 30).

166 Descriptive statistics and frequency tables of weighted data were used to describe the bike riding
167 behaviours and frequency of each Geller Typology, and to make comparisons between age, gender and
168 region of residence. Chi-square tests were used to examine differences in the distribution of the Geller
169 Typology within age, income, and gender groups, and between Greater Melbourne and regional Victoria.

170 **Ethics**

171 The project was approved by the Monash University Human Research Ethics Committee (Project ID: 25346).

172 **RESULTS**

173 In total, 41,000 invitations and 20,000 reminders were sent by the ORU, with a response rate of 10%. Of the
 174 4067 participants who started the survey, 3999 (98%) completed all sections and were included in the final
 175 analysis. The age and gender of the weighted sample were generally consistent with the aggregated
 176 population of the LGAs included in the study, with only the 65-74-year age group being 6.9% higher in the
 177 sample than the target population (see Supplementary Materials C). The weighted sample had a higher
 178 income than the target population, with 15% of participants earning over \$104,000 per year compared to
 179 7.2% of the target population. In the sample, 12% spoke a language other than English at home, compared
 180 to 26% in Victoria (see Supplementary Materials C).

181 Over half of all participants owned a bike (57%), however only 20% rode their bike at least once per week.
 182 Of participants that rode their bike at least once a year, most rode for recreation only (72%).

183 Over three quarters of the sample (78%) were classified as Interested but Concerned, 2.8% as Strong and
 184 Fearless, 3.2% as Enthused and Confident and 16% as No Way No How (see Figure 4). The Interested but
 185 Concerned group comprised a higher proportion of women (48%) than the Strong and Fearless (28%) and
 186 Enthused and Confident groups (25%) (Table 1). Over half of this group owned a bike (63%), and most rode
 187 for recreation only (73%), and rode 1-3 times per year (31%). Twenty-six percent of participants in this
 188 group had not ridden a bike in the past 12 months, showing a potentially latent group of bicyclists.

193 *For the counts of participants who identified as “non-binary” or “other”, or reported “prefer not to say”, robust analysis could not
194 be performed due to small sample sizes

195 **based on participants who had ridden a bike in the 12 months previous to COVID-19 restrictions

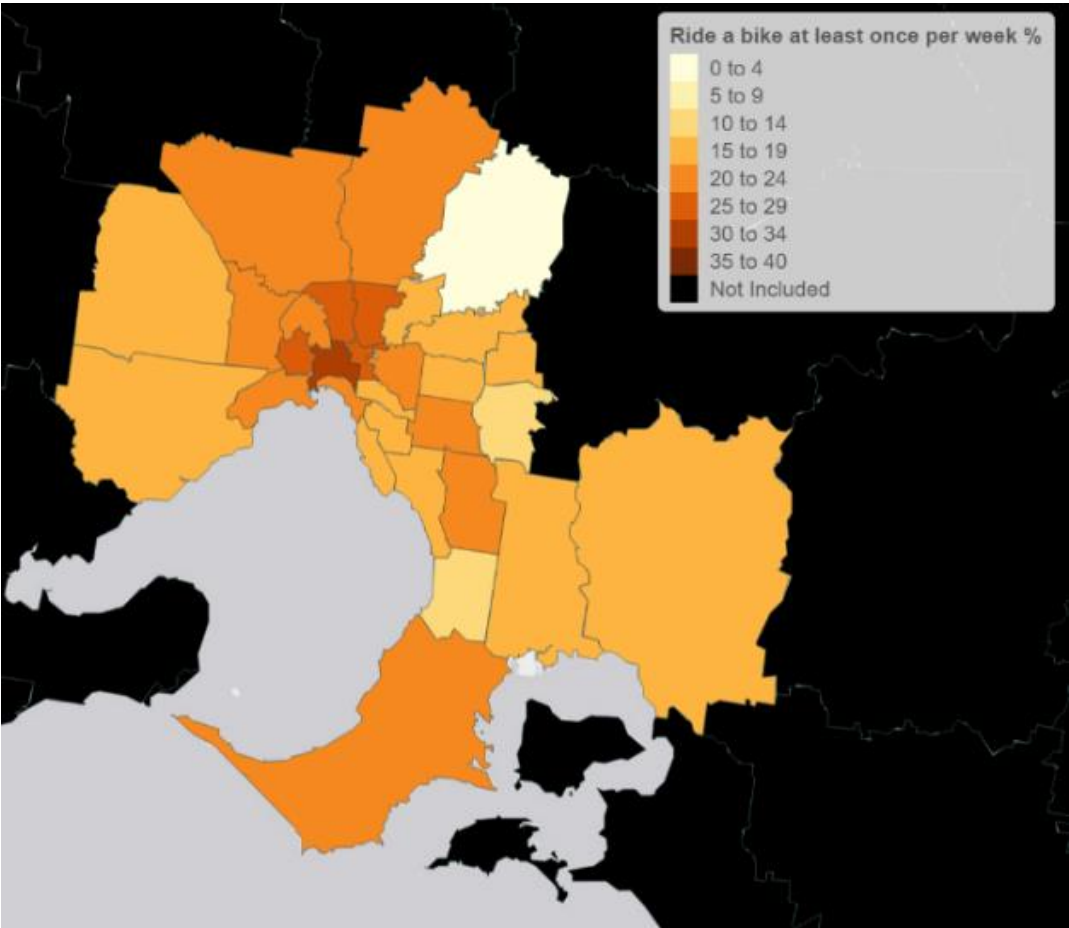

196 **Within Greater Melbourne comparisons**

197 In Greater Melbourne, the Interested but Concerned group was consistently the largest group across all
198 LGAs, ranging from 66% to 88% (Figure 5). Many of the LGAs on the outer-fringe area of Greater Melbourne
199 had higher proportions of Interested but Concerned participants. The proportion of Strong and Fearless
200 were low in all LGAs, ranging from 0.0 to 7.1%. Similarly, proportions of Enthused and Confident
201 participants were low, ranging from 0.0% to 7.3%. Proportions of No Way No How participants ranged
202 from 2.7% to 23%.

204 *Figure 5. Heat map of Greater Melbourne showing the proportion of participants categorised as Interested but Concerned*

205 Bike ownership was highest in the inner-West (67%), and lowest in inner-East areas, where in one LGA, only
206 40% of participants owned a bike. Participants who rode a bike at least once per week were most common
207 in the City of Melbourne (32%), and generally decreased with distance from the city (Figure 6).

208
209 *Figure 6. Heat map of Greater Melbourne showing the proportion of participants who rode a bike at least once per week prior to*
210 *COVID-19 restrictions*

211 **Regional comparisons**

212 Proportions of Geller groups differed significantly between Greater Melbourne and regional Victorian LGAs
213 ($\chi^2 = 19.4$, $p = <0.001$). For both Greater Melbourne and regional Victorian LGAs, the Interested but
214 Concerned group made up the majority of the sample (79% and 71% respectively). A higher proportion of
215 participants were classified as No Way No How in regional Victoria (21%) than Greater Melbourne (15%),
216 however bike ownership was comparable between regional Victoria (60%) and Greater Melbourne (57%).
217 There was no association between how often participants rode a bike based on regionality ($\chi^2 = 0.5$, $p = 3.5$)
218 (Supplementary Material C).

219 **Age Comparisons**

220 More than half of each sample were Interested but Concerned in all age groups (Figure 7). There was an
221 association between age group and the Geller distribution ($\chi^2 = 214.7, p = <0.001$). The proportion of
222 participants classified as Interested but Concerned was lower in participants aged 55-74 years (72%) and 75
223 or more years (55%) compared to participants aged 18-34 years (84%) and 35 to 54 years (83%). The
224 proportion of participants classified as No Way No How was highest in participants aged 75 years and older
225 (42%) and 65-74 years (28%).

226
227 *Figure 7. Distribution of Geller groups within age categories (weighted)*

228 **Gender comparisons**

229 A higher proportion of men than women in the sample owned a bike (63% vs. 52%), rode a bike at least
230 once per week (28% vs. 12%) and rode a bike solely for transport (8.3% vs. 5.9%). The distribution of Geller
231 groups differed between women and men ($\chi^2=79.7, p=<0.001$) (see Figure 8). While the proportion of No
232 Way No How participants was higher in women (19% vs 12%) and the proportion of Strong and Fearless
233 (1.6% vs 4.0%) and Enthused and Confident (1.6% vs 4.7%) participants were lower in women, the
234 proportion classified as Interested but Concerned was comparable in both women (78%) and men (79%).

Figure 8. Distribution of Geller groups by gender (weighted)

Income comparisons

A higher proportion of participants in the lower income groups (\$1 - \$20,799/year and \$20,800 - \$41,599/year) rode a bike more for transport, and a greater proportion rode four or more days per week than any other income groups. High income groups had the highest proportion of recreational bike riding (78% in participants earning \$104,000 or more per year), and highest proportion of participants riding a bike 1-3 times per week (7.1% in \$65,000 - \$103,999/year group).

The proportion of Interested but Concerned participants ranged from 73% in the \$20,800 - \$41,599 income group to 82% in the \$41,600 - \$64,999 income group. The highest proportion of Strong and Fearless participants (4.2%) was in the group earning \$104,000 per year or more (Figure 8 and Supplementary Material C).

Figure 8. Distribution of Geller groups by gross income group (weighted)

250 **DISCUSSION**

251 There is currently no data available on how interest in riding a bike differs between geographical regions,
252 and no data on the Geller typologies in Australia. This study quantified the proportion of each Geller
253 typology group across 37 LGAs in Victoria, Australia with complete data from 3999 individuals. Over half of
254 participants owned a bike, however only one in five rode a bike at least once per week. Most participants
255 were classified as Interested but Concerned, demonstrating a high latent demand for bike riding if
256 protected bicycling infrastructure were provided. Geller group distributions differed between LGAs within
257 Greater Melbourne, and between regional and metropolitan areas, supporting the need for analysis of
258 Geller groups at smaller spatial scales than cities or states.

259

260 Few studies have used original research to identify the Geller typology proportions (8-11). Two sentinel
261 Geller papers from the US (7, 8), one of which is published research, are often extrapolated to local
262 government and state planning strategies in other areas (6, 31-34). Original research to identify Geller
263 typology proportions has been conducted in the United States; including Portland (8, 9), Austin (9), Chicago
264 (9), San Francisco (9), Washington D.C. (9), and in Edmonton, Canada (10). At times, these findings are
265 applied to settings outside of where the data were collected. For example, the original paper from Roger
266 Geller (7), based in Portland in the United States, has been cited in the Victorian Cycling Strategy in
267 Australia (6). Research conducted in this area suggests 58% of people living in Portland are Interested but
268 Concerned (8). Our Victorian-specific data demonstrates a far higher proportion classified as Interested but
269 Concerned (78%).

270

271 Previous published studies using the Geller Typology to quantify interest in bike riding have done so at a
272 multi-city, state and city level (8-11). To the authors' knowledge, our study is the first to quantify the Geller
273 typology proportions at a smaller spatial scale. We found that interest and confidence in riding a bike
274 ranged from 66% to 88% within the metropolitan area of Greater Melbourne. These differences may come
275 from differing available infrastructure, the demographics of an area, trip distance to central hubs and

276 physical setting (e.g. topography, primary land-use type) (35, 36). Further, it is important to identify these
277 variations to understand the interest across areas with substantially different availability of bicycle
278 infrastructure. While variation in Geller typologies was observed across Greater Melbourne, one of the
279 most important findings was that interest in bike riding was consistently high, including in outer urban
280 fringe regions of Greater Melbourne, revealing a high latent demand across a vast geographical area of an
281 entire metropolitan region. Currently, however, bicycling infrastructure is concentrated in inner-Melbourne
282 to support higher volumes of bike traffic (12, 13). Therefore, bicycling infrastructure is not equitably
283 provided across differing regions of Greater Melbourne (12, 13), likely contributing to both transport
284 inequities (38), and health inequities through reduced physical activity participation (39) and a potentially
285 increased risk of injury (40-44). The provision of protected bicycling infrastructure has the potential to
286 address these inequities and support a potentially latent population of bike riders living in the outer urban
287 fringe regions of Greater Melbourne (45-51). This would further enable current recommendations in
288 Greater Melbourne of the “20-minute-neighbourhood” model, that supports people to meet most of their
289 daily needs within a 20-minute trip from home (by walking, riding a bike or using public transport) (52). To
290 inform the provision of locally-specific infrastructure, additional research is required to better understand
291 trip purposes in outer urban fringe regions, and if they are focussed on transport to inner-city areas, or are
292 for accessing local hubs and public transportation.

293

294 Women are often under-represented in bike riding campaigns and popular culture due to lower
295 participation, and the perspective of bike riding being a male-dominated activity (17, 53, 54). Despite low
296 participation, over two thirds of women in this study were interested in riding a bike. Importantly, many
297 existing bike riding environments are often designed for the needs and confidence levels of able-bodied
298 men (55-57). Infrastructure that enables women to ride a bike includes off-road paths, and bike-
299 infrastructure that is physically separated from motor-vehicle traffic (55, 58). In future urban planning and
300 research, it is vital that a lack of participation is not seen as a lack of interest in bike riding. Understanding

301 the barriers to riding a bike for women, who are often under-represented in the bike riding community is
302 important to increasing participation.

303

304 In this study, a higher proportion of people in the lower income categories rode a bike for transport
305 purposes, and rode four or more days per week, compared to people in the higher income groups. Similar
306 findings have been shown both in Australia and internationally, where there was an association between
307 increased household income, and a decreased proportion of people riding a bike for transport (12, 59, 60).
308 People in lower income groups may ride a bike out of necessity for commuting, rather than as a
309 recreational activity. Despite this, people living in areas of lower socioeconomic status have
310 disproportionately lower access to bicycling infrastructure (14, 61, 62). In Melbourne, much of the
311 protected bicycling infrastructure are off-road paths located in parks, along rivers as trails, often in inner-
312 city, higher socioeconomic areas (12, 13), with similar patterns internationally (14, 61-63). To support lower
313 income groups in bicycle-commuting and reduce health inequities faced by low socioeconomic groups,
314 high-quality and protected bicycling infrastructure should be provided equitably to support local travel and
315 connections with public transport.

316

317 The provision of separated bicycling infrastructure is important for both the safety (64) and support of low
318 risk bicycling environments to maintain and encourage participation. While painted bike lanes are a lower
319 cost alternative to providing bicycling infrastructure, these do not constitute physically separated bicycling
320 infrastructure. Research conducted in Melbourne that measured passing distances between motor vehicles
321 and bikes identified more close, and potentially unsafe, passes when a person riding a bike was travelling in
322 a painted bike lane compared to on-road (65). Similarly, a previous study identified that 22% of all on-road
323 bike riding crashes occurred while riding in a painted bike lane, highlighting their insufficiency in protecting
324 vulnerable road-users (66). In addition to the risk of substantial injury that painted bike lanes pose for
325 people on bikes, they are not supportive of new bike riders, or low-stress traffic environments, with
326 concerns about safety on the road and interactions with motorists being a major barrier to participation in

327 bike riding (17, 67-70). Removing interactions with motor vehicles through a physically separated bicycle
328 lane could substantially increase participation in bike riding in Melbourne, while maintaining the safety of
329 vulnerable road-users.

330

331 To our knowledge, this was the first study of Geller typologies in Australia, and the largest and most
332 population-representative for trip purpose and bike riding frequency. Further, this was the first application
333 of the Geller typology at a small spatial scale, demonstrating important differences between local
334 government areas. Despite this, some limitations were present. A recently published mixed methods study
335 raised concerns over the internal validity of the Geller typology, particularly that the category participants
336 were assigned to did not always represent their confidence in riding a bike (71). However, this typology was
337 used because of its ease of understanding with policy makers, and to enable comparisons to existing
338 literature and government bike riding strategies. Additionally, using an online research company may have
339 favoured participants with a higher income, with computer access, and whom are able to regularly check
340 their email, potentially introducing selection and response bias. To reduce response bias, invitations to
341 complete the survey were sent in batches and at different times during the week. This enabled people who
342 may have been occupied on certain days to receive a notification about the survey. As recommended by
343 Hay et al., convenience internet panels are useful when data can be weighted to compensate for coverage
344 errors (72). Some regional LGAs in this study had a low number of research company panel members. In
345 turn, only a small number of participants completed surveys and represented the population in those LGAs.
346 To reduce potential coverage errors, whole sample results were weighted by the population size of each
347 LGA in an effort to balance the effects of under and over sampling across LGAs.

348 **CONCLUSION**

349 To our knowledge, this study was the first application of the Geller typology groups at a small geographical
350 area level. We demonstrated that while there was variation in interest in bike riding across an entire
351 metropolitan region, interest was high across all LGAs, including outer urban areas that currently have
352 lower participation in bike riding. Similarly, despite participation in bike riding being lower in women,

353 interest remained high. It is vital that a lack of participation is not seen as a lack of interest in bike riding.
354 These findings are important in considering the role that bike riding can play in reducing health and
355 transport inequities and how protected bicycling infrastructure can be implemented to address these
356 inequities. Further research is required to identify what factors are preventing people in Victoria from
357 riding a bike and how these barriers vary across geographical areas.

358 **ACKNOWLEDGEMENTS**

359 The authors would like to acknowledge the contribution of the participants in this study.

360 **FUNDING**
