17 Abstract

Background: School violence and injury are major public health problems worldwide; however,
current information on these issues in Vietnam is lacking. We aim to investigate the prevalence of
violence and non-fatal injury and associated factors among Vietnamese adolescents aged 13-17
years old.

Methods: We used data from the 2019 Vietnam Global School-based Student Health Survey (GSHS), which is a nationally representative survey developed by the World Health Organization to monitor behavioral risk factors among school-aged students. The Vietnam GSHS 2019 was conducted in 20 provinces and cities, with a sample size of 7,690 male and female students aged 13-17 years old.

Results: We found the prevalence of violence and non-fatal injury was 14.5% and 21.4%, respectively. Common risk factors for both violence and non-fatal injuries included cigarette smoking, alcohol use, mental health problems, and living with neither parent; violence was also a risk factor for non-fatal injuries. Student older age was associated with lower odds of school violence. Parents played an important role in preventing violence among female students and non-fatal injuries in both genders.

33 Conclusions: Future policies should consider individual factors as well as adolescent-parent
34 bonding, to mitigate the burden of violence and injury among in-school adolescents in Vietnam.

35 Key words: Violence, Non-fatal Injuries, Adolescents, GSHS, Vietnam

37 Introduction

School violence occurs when a student is physically attacked or involved in a physical fight at 38 school, on the way to/from school, or at school-related events. Every year, 200,000 homicides 39 occur among young people aged 10-29 years old worldwide.¹ Furthermore, violence has serious, 40 life-long impacts on physical health, psychological health, and the social functioning of young 41 people.¹ In a study of student victimization across 37 nations, an average of 27.8% of students 42 reported that they had been victims of school violence at least once in the month preceding the 43 survey. Countries with the highest rates of victims of school violence are Hungary, Romania, and 44 the Philippines.² The prevalence of violence among 68 low-to-middle-income countries (LMICs) 45 is 35.6%.³ Indeed, school violence is prevalent in many countries around the world, which makes 46 it a global public health concern. 47

Serious non-fatal injuries result from various causes, including violence. The classification of 48 serious injury is when an individual is forced to miss at least one full day of normal activities (such 49 as school, sports, or work), or requires treatment by a doctor or a nurse. These injuries lead to more 50 than 5 million deaths annually and are a major public health problem.⁴ Moreover, injury is among 51 the leading causes of death among adolescents worldwide.⁵ A research study that looked at 11-, 52 53 13-, and 15-year-old adolescents in 11 industrialized countries, reported that 41.3% of all children had been injured and needed medical treatment in the preceding 12 months.⁶ Among 68 LMICs, 54 serious injury affected 47.8% of male students and 37.5% of female students.³ The Global School-55 based Student Health Survey (GSHS) in four Southeast Asian Countries reported an average of 56 42.2% of adolescents having suffered one or more serious injuries within the preceding 12 57 months.⁷ 58

The current literature reports that, among students, school violence is associated with suicide ^{8,9}; injury is associated with poor mental health¹⁰⁻¹³ and violence;^{9,11,13-15} and both violence and injury are associated with substance use^{7-9,11,16} and truancy.^{9-11,17} Insufficient parental supervision⁹ and lack of parental bonding¹³ are risk factors for violence and injury, while parental respect and parental support are protective factors.^{8,17}

Vietnam is a low-to-middle-income country in the Southeast Asia region, with a population of 64 95.5 million.¹⁸ According to GSHS 2013, 34.3% of male middle-school students, and 25.1% of 65 female middle-school students in Vietnam, experienced one or more serious injuries.¹⁹ Although 66 there are some published papers on violence and injury in industrialized countries and on the 67 overall status in LMICs, scientific evidence on violence or injury and associated factors in Vietnam 68 is very scarced, since school violence is a sensitive topic in Vietnamese culture. In Vietnam, 69 70 schools with a high prevalence of violence are likely to suffer from negative media coverage and gain a bad reputation; therefore, school officials may have little incentive to facilitate research on 71 school violence. GSHS 2019 was supported by both the Ministry of Health and the Ministry of 72 73 Education and Training in Vietnam, which facilitated data collection in schools across the whole country and allowed preparation of a nationally representative report of both violence and injury 74 75 among Vietnamese school students.

In this study, we used data from GSHS 2019 to report on the status of these two topics in Vietnam and to provide the most up-to-date information on the prevalence of violence and non-fatal injury in Vietnam in 2019 and their associated factors.

80 Methods

81 Data source

This study used data resulting from the Vietnam GSHS 2019, which is a nationally representative survey of students aged 13-17. Hanoi University of Public Health conducted this survey in collaboration with the General Department of Preventive Medicine, the Ministry of Health, and the Ministry of Education and Training, Vietnam. The World Health Organization (WHO) and Center for Disease Control (CDC) provided financial and technical assistance. GSHS 2019 consists of core questionnaire modules with expanded and country-specific questions that cover key areas of behavioral risk factors and protective factors among school-age adolescents.

89

90 Study setting and participants

GSHS 2019 followed the WHO standardized study design, using cross-sectional two-stage cluster 91 sampling to obtain a representative sample of students in senior secondary schools (grades 8-9) 92 93 and high schools (grades 10-12). The Vietnam GSHS 2019 was conducted in 20 provinces and cities. In the first stage, we selected schools based on the probability proportional to size sampling 94 technique. To make the sample representative for subpopulations, we stratified the sample by place 95 of residence (rural/urban) and school level (senior secondary/high school). We selected a sample 96 size of 1,500 and a response rate of 90% for each stratum, to ensure a margin of error of less than 97 5%. In the second stage, we applied a simple random sampling technique to choose classes from 98 each selected school. All students in the selected classes were eligible to participate in the study 99 regardless of their actual age. In total, we collected data from 7,796 students in 81 schools and 210 100 101 classes. The school and student response rate was 96.4% and 97.0%, respectively.

103 Study instruments

We used the WHO standardized GSHS questionnaire to develop the Vietnam-specific instrument. Firstly, we applied forward and backward translation of the English version. Some countryspecific questions were then added to form the initial version of the Vietnam GSHS 2019 questionnaire. The instrument was pre-tested in the target population at two schools in Hanoi, Vietnam. After the pre-test, the questionnaire was revised to ensure that students could understand and complete the survey within the allocated time. These students were excluded from the final sample.

111

112 Data collection

Before collecting data at the selected classes, we obtained written informed consent from the students' parents/guardians with the assistance of the school administrators. In the ensuing days, we surveyed the students who had a completed consent form from their parents/guardians and who were willing to participate in the study. Students answered the self-administered questionnaire on separate, computer scannable answer sheets, during one classroom period.

118

119 Study variables

120 **Table 1** provides the variable definitions of this study.

121 Outcome variables

The two outcome variables of the study are violence and non-fatal injuries. Violence was assessed by asking students if they had experienced any physical attacks or been involved in any physical fight in the preceding 12 months. Non-fatal injuries were assessed by asking students if they had been seriously injured in the previous 12 months.

126 Independent variables

127 We assessed the potential correlates of violence and non-fatal injuries, including demographic characteristics (gender, age, place of residence, living with parents); parental factors (parental 128 129 monitoring, parental support, parental respect, parental expectation); number of close friends; risk behaviors (alcohol use and the smoking of cigarettes); mental health problems (suicide attempt, 130 131 loneliness, worrying); and truancy. The details on the variable definitions are shown in Table 1. 132 (Table 1 is about here) 133 134 **Data analysis** We used frequency and weighted percentages to describe the categorical variables: weighted 135 percentage and 95% confidence interval (CI) to compare the prevalence of violence and injury 136 137 across groups. Since the patterns of violence and injury are potentially different between gender groups, we stratified all analyses by gender. In this study, among 7,796 students, 106 self-identified 138 as other-gender. Due to the small sample of the other-gender group, we included only male and 139 140 female gender (n = 7,690) in the stratified analyses. To identify factors related to the outcomes of interest, we applied multivariate logistic regression. 141 142 The variables included in the multivariate models were based on our literature review of potential

143 covariates of violence and injury among school-aged adolescents. We utilized the survey package

144 "svy" in Stata version 16 SE (StataCorp, College Station, TX, USA) to account for the cluster

sampling design and sampling weights of the GSHS. We reported the odds ratio (OR) and 95% CI

146 for modeling results and used a significance level of 0.05 for all statistical tests.

148 **Results**

149 *Participant characteristics*

Table 2 describes the characteristics of the study participants. More than half of the students were 150 female (54.0%), attending secondary school (55.5%), and living in rural areas (63.5%). Most of 151 the participants lived with both their mother and father (72.4%). Regarding parental factors, 47.7% 152 153 of parents were involved in their children's homework and free time, 55.8% understood and gave advice and guidance, 85.7% had respect, and 54.8% had a high expectation of their children. About 154 two-thirds of the students had three or more close friends, 44.0% drank alcohol, and 8.2% smoked 155 156 cigarettes. Regarding mental health, 12.3% of the students felt lonely, 6.1% felt worried, and 15.4% had attempted suicide in the preceding 12 months. Around 15.1% of the students had 157 committed truancy in the previous 30 days. 158

159

(Table 2 is about here)

160 Violence and non-fatal injury prevalence

The prevalence of violence and non-fatal injury among Vietnamese adolecents in 2019 was 14.5% 161 (95% CI: 12.6-16.6) and 21.4% (95% CI: 19.8-23.2), respectively. This prevalence was 162 significantly higher in males than in females, with 21.7% (95% CI: 18.1-25.7) vs. 8.3% (95% CI: 163 164 7.4-9.5) experiencing violence, and 27.7% (95% CI: 24.6-31.1) vs. 16.1% (95% CI: 14.5-17.8), sustaining non-fatal injuries. The prevalence of violence decreased by age; ranging from 32.4% 165 (95% CI: 24.7-40.2) to 12.6% (95% CI: 8.4-16.8) among males, and 11.1% (95% CI: 7.3-14.9) to 166 4.6% (95% CI: 3.2-6.0) among females, while differences in non-fatal injury prevalence were not 167 significant between age groups (Figure 1). 168

169 Details of the prevalence of violence and non-fatal injury by student characteristics are available

170 in **Supplemental Table 1**.

171

(Figure 1 is about here)

172 Factors related to violence

Figure 2 shows the results of multivariable logistic model of factors related to violence among 173 174 adolescents aged 13-17 in Vietnam in 2019. Conditional on all other factors, drinking alcohol is associated with significantly higher odds of violence among male students (OR = 2.11, 95% CI: 175 176 1.45-3.07). Female students living in urban areas or living with neither father nor mother were likely to have higher odds of violence (OR = 1.35, 95% CI: 1.01-1.82, and OR = 1.52, 95% CI: 177 1.01-2.28, respectively), whereas those with high parental respect had lower odds of violence (OR 178 179 = 0.58,95% CI: 0.41-0.82). Smoking cigarettes, loneliness, and suicide attempts were significantly associated with increased odds of violence, while higher age was a protective factor against 180 violence in both genders. 181

182

(Figure 2 is about here)

183 Factors related to non-fatal injuries

Figure 3 shows the findings of multivariable logistic model of factors associated with non-fatal 184 injuries among Vietnamese adolescents aged 13-17 in 2019. We found that male students living 185 with neither mother nor father and smoking cigarettes had a higher likelihood of non-fatal injury 186 187 (OR = 1.30, 95% CI: 1.07-1.58, and OR = 1.43, 95% CI: 1.08-1.88, respectively). Among female students, higher odds of non-fatal injury were found in those who felt worry (OR = 2.06, 95% CI: 188 1.34-3.17), had attempted suicide (OR = 1.40, 95% CI: 1.13-1.72), and drank alcohol (OR = 1.40, 95% CI: 1.13-1.72). 189 190 95% CI: 1.09-1.80). In contrast, female students with parental respect had 40% lower odds of nonfatal injuries (OR = 0.60, 95% CI: 0.42-0.84). In both genders, exposure to violence was a 191 192 significant risk factor for non-fatal injuries.

193

(Figure 3 is about here)

194 Discussion

In this study, we found that the prevalence of violence among Vietnamese students aged 13-17 is 195 14.5% and the prevalence of non-fatal injury is 21.4%. Violence and non-fatal injury are both more 196 prevalent among male students compared to female students. Older students are less likely to be 197 involved in violence, although a higher age is not a protective factor for non-fatal injury. Risk 198 199 factors for violence among students include alcohol use, smoking cigarettes, mental health problems, living in urban areas, and living with neither parent. For non-fatal injury, risk factors 200 include smoking cigarettes, alcohol use, living with neither parent, violence, and mental health 201 202 problems. It is notable that parental factors have a significant impact on female students regarding both violence and non-fatal injury. Parental respect significantly reduces the odds of violence and 203 non-fatal injury among female students, while living with neither parent increases the risk of 204 violence. Our findings serve as evidence for developing effective prevention and action strategies 205 206 to mitigate the burden of violence and injury among adolescents in Vietnam and other low- and 207 lower-middle-income countries.

Previous studies have reported that the prevalence of violence is different across countries. Han et 208 al.³ found the prevalence of physical attack and physical fighting among 68 low-middle-income 209 210 countries (LMICs) from 2009 to 2015 to be 35.6 (95% CI: 30.7-40.5) and 36.4 (95% CI: 29.9-211 42.9), respectively. The prevalence was lower in high-income countries. For example, the Youth Risk Behavior Survey in 2015 showed that 23.6% (95% CI: 21.6–25.6) of adolescents in the USA 212 had been involved in a physical fight.²⁰ The prevalence of physical fighting (defined as at least 213 four incidents of fighting in the previous 12 months) among adolescents in the USA and Northern 214 European countries is less than 6.5%.²¹ The overall prevalence of violence in our study was lower 215 than the findings from other countries. The differences in these prevalence estimates might be 216

217 explained by the cultural differences between countries in terms of violence. The year when the 218 surveys were conducted might also account for the variation, given that the prevalence of violence in Vietnam in 2013 was 27.2% (95% CI: 24.1–30.5),²² which was similar to other countries at that 219 220 time. A systematic analysis of the global updated data is unfortunately not available; however, it can be observed that the prevalence of violence among Vietnamese students in 2019 reduced 221 significantly compared to 2013. This reduction might be due to Vietnam's rapid economic growth, 222 and more attention and investment being given to education. A previous study demonstrated the 223 relationship between spending on education and the prevalence of physical fighting among 224 adolescents.²¹ Furthermore, reduction in school violence prevalence in Vietnam would not have 225 226 been possible without the crucial role of the Ministry of Education and the coordinated effort of school governers and staffs. In 2017, the Ministry of Education issued Decision 5886 which 227 consisted of a comprehensive action plan for prevention and control of school violence.²³ Indeed, 228 it is very important to integrate violence prevention content not only in formal curriculum but also 229 in extracurricular activities. The decision also emphasizes the importance of communication 230 231 activies, safe school environment and training for school staffs. It is also notable that the prevalence of violence in our study includes not only students who were victims of violence but 232 233 also those who were actively involved in physical fights. From our study, it was found that 10.42% (95% CI: 8.98-11.87) of students were physically attacked. Male students were more likely to be 234 victims of violence (15.4%, 95% CI: 12.55-18.26) compared to female students (6.05%, 95% 235 236 CI:5.28-6.83).

Our results regarding the prevalence of non-fatal injuries among young adolescents are relatively lower than studies from other LMICs. For instance, the prevalence of injury across 68 countries reported by Han et al.³ was 42.9% (95% CI: 39.0–46.9), in which the highest prevalence was found

in the African region, with 48.1% (95% CI: 40.2–55.9). Street et al.²⁴ analyzed the data from 95,811 students aged 13–15 years in 47 LMICs between 2003 and 2012 and found that 39.9% (95% CI: 35.1–44.8) of the participants reported at least one serious injury during the preceding 12 months. Similar to Han et al.,³ Street et al. also showed that the highest percentages were in Samoa (72.1%) and six countries in Sub-Saharan Africa.²⁴ The differences in prevalence estimates in our study and the above studies might be explained by the differences in the location where the surveys were conducted; the two previous studies included many high-risk regions.^{3,24}

Non-fatal injuries among school-aged adolescents in Vietnam in 2019 were also less prevalent 247 compared to 2013 (29.3%).²² This result shows great progress in injury prevention in Vietnam. 248 249 Multisectorial effort among the Ministry of Health, the Ministry of Education, and the Ministry of Labour – Invalids and Social Affairs has led to implementation of many injury prevention 250 251 activities in the community, focusing on communication to raise awareness, education for school staff and parents, and building safe communities for children and adolescents. However, this 252 prevalence figure was still higher than that reported among adolescents in developed countries; for 253 example, from 9.8% to 7.8% between 2003 and 2011 in Spain.²⁵ This finding indicates that despite 254 efforts on injury prevention, serious injury should be considered as a public health priority, 255 256 particularly in LMICs with limited resources for healthcare.

Regarding gender, our results indicate that male students suffer more violence and injury than female students. These results are consistent with previous studies^{17,19,25} and may be because boys are more physically active than girls, and tend to get involved more easily in competitive activities such as physical fights and games.^{26,27} We observed many common risk factors for violence and non-fatal injury, including the smoking of cigarettes, alcohol use, mental health problems, and living with neither parent, with violence also being a risk factor for injury. These findings are

consistent with research from many other countries.^{7-9,28-30} Notably, mental health is a risk factor 263 for non-fatal injuries among female students and for violence in both genders, which accords with 264 previous studies.^{29,31} With the popularity of social platforms and rapid access to a wide range of 265 266 information, Vietnamese students may face an increased risk of mental health problems, which is particularly worrying given that mental health is also associated with violence and non-fatal injury. 267 Moreover, parents were found to play a crucial role in preventing violence and non-fatal injury 268 among Vietnamese students; this may be explained by Vietnamese family culture, where parents 269 and children have close bonds, and parents are often involved in children's education, personal 270 271 development, and even daily activities. Studies from other countries have also indicated that the 272 better and closer the parent-children relationship is, the less likely violence and injury among children will occur.³²⁻³⁴ Wright and Fitzpatrick reported that certain aspects of the parent-273 274 adolescent relationship, such as trust, involvement, and connection, are protective factors of adolescent violence.³⁴ The relationship between parent and child may also impact adolescents in 275 276 other ways, such as preventing depression and self-harm behaviors, and in turn, preventing violence and injury.³⁵ Together, our findings highlight the need for the implementation of effective 277 public health interventions that take into account a comprehensive list of factors to mitigate the 278 279 burden of violence and injuries among adolescents in Vietnam, including behavioral risk factors, mental health, and adolescent-parent bonding. 280

281

282 Strengths and limitations

A strength of our study is the large and nationally representative sample, using a standardized study design and research method. The study also used the most recent dataset (GSHS 2019) to provide a timely assessment of the status of violence and non-fatal injury among adolescents in

286 Vietnam, and associated factors. Furthermore, the results from this study account for a wide age range of adolescents (13-17 years old), and are comparable across the country. However, we also 287 recognize some limitations of our study. First, due to its self-reporting nature, the information 288 289 obtained through the survey may be subject to recall bias. Second, although most adolescents in Vietnam are in school, this study focused only on in-school adolescents, which may not be 290 291 representative of all adolescents, including those who are not in school. Thirdly, given the crosssectional design, we could not confirm causal inferences and were not able to evaluate the long-292 term consequences of violence and injury. 293

294

295 Conclusion

Despite the reduction in rates of violence and non-fatal injury, the prevalence of these issues is still relatively high among students in Vietnam. Common associated factors of violence and nonfatal injuries include behavioral risk factors, mental health problems, and parental factors. Future policies should consider both individual factors as well as adolescent-parent bonding in order to reduce the burden of violence and injury among adolescents in Vietnam.

Table 1: Variable definitions

Variables	GSHS 2019 questionnaire	Definition used in this paper		
Dependent variables	•			
Violence	 During the past 12 months, how many times were you physically attacked? During the past 12 months, how many times were you in a 	Students who were physically attacked or involved in physical fight at least 1 time during the		
	physical fight? 1 "0 times" to 8 "12 times"	past 12 months Yes vs. No		
Injury	During the past 12 months, how many times were you seriously injured? 1 "0 times" to 8 "12 times"	Students who were seriously injured at least 1 time during the past 12 months Yes vs. No		
Independent variable				
Gender		Male vs. Female		
Age		13 – 17		
Place of residence Living with	Do you live with both of your parents?	Rural vs. Urban Both parents, Mother or father, or Neither		
Parents monitoring	- During the past 30 days, how often did your parents or guardians check to see if your homework was done?	Students whose parents most of the time/always checked		
	 During the past 30 days, how often did your parents or guardians really know what you were doing with your free time? 1 "Never" to 5 "Always" 	homework or know what their children do in their free time <i>High vs. Low</i>		
Parents respect	 During the past 30 days, how often did your parents or guardians go through your things without your approval? During the past 30 days, how often did your parents or guardians not respect you as a person (for example, not let you talk or favor someone else more than you)? <i>I. "Never" to 5. "Always"</i> 	Students whose parents most of the time/always respect their children or their personal space <i>High vs. Low</i>		
Parents support	 During the past 30 days, how often did your parents or guardians understand your problems and worries? During the past 30 days, how often did your parents or guardians give you advice and guidance? 1 "Never" to 5 "Always" 	Students whose parents most of the time/always understood problems/worries or gave advice/guidance <i>High vs. Low</i>		
Parents expectation	- During the past 30 days, how often do your parents or guardians expect too much of you (for example, to do better in school or be a better person)? 1 "Never" to 5 "Always"	Students whose parents most of the time/always expect too much on their children <i>High vs. Low</i>		
Number of close friends	How many close friends do you have?	0, 1, 2, 3 or more		
Alcohol use	How old were you when you had your first drink of alcohol? 1 "I have never had a drink of alcohol", 2 "I have never had a drink of alcohol other than a few sips", 3 "7 years old or younger" to 9 "18 years old or older"	Students who has ever drunk alcohol (rather than a few sips) <i>Yes vs. No</i>		
Smoke cigarettes	How old were you when you first tried a cigarette? 1 "I have never smoked cigarettes", 2 "7 years old or younger" to 8 "18 years old or older"	Students who has ever smoked cigarettes <i>Yes vs. No</i>		
Truancy	During the past 30 days, on how many days did you miss classes or school without permission? 1 "0 days" to 5 "10 days or more"	Students who missed any days without permission during the past 30 days Yes vs. No		

Variables	GSHS 2019 questionnaire	Definition used in this paper
Loneliness	During the past 12 months, how often have you felt lonely?	Students who most of the
	1 "Never" to 5 "Always"	time/always felt lonely during
		the past 12 months
		Yes vs. No
Worried	During the past 12 months, how often have you been so	Students who most of the
	worried about something that you could not eat or did not	time/always felt worry during
	feel hungry?	the past 12 months
	1 "Never" to 5 "Always"	Yes vs. No
Suicide attempt	During the past 12 months, did you ever seriously consider	Students who seriously
	attempting suicide?	considered attempting suicide
	1 "Yes" to 2 "No"	Yes vs. No

431 Table 2: Participants' characteristics

Characteristics		Total		Male		Female	
Characteristics	n	Weighted %	n	Weighted %	n	Weighted %
