Validation of a multi-gene qPCR-based pharmacogenomics panel across major ethnic groups in Singapore and Indonesia

Running Title

Multi-gene qPCR-based PGx panel for Asians

Acknowledgements

We would like to thank Mr. Xie Zhicheng and Mr. Heng Khai Koon at the Genome Institute of Singapore for their assistance with performing the Agena VeriDose® Core and *CYP2D6* CNV Panel studies. We also thank PT Nalagenetik Riset Indonesia for their assistance in study recruitment and experimentation performed in Indonesia, and Genome Institute of Singapore for providing facility to perform all experimentations done in Singapore.

Abstract

Background – With up to 70% of adverse drug reactions (ADRs) having high genetic associations, the clinical utility of pharmacogenomics (PGx) has been gaining traction. Nala PGx Core™ is a multi-gene qPCR-based panel that comprises 18 variants and 2 *CYP2D6* Copy Number markers across 4 pharmacogenes – *CYP2C9*, *CYP2C19*, *CYP2D6* and *SLCO1B1*.

Objectives – In this study, we validated the performance of Nala PGx Core™ against benchmark methods, on the Singaporean and Indonesian populations. Additionally, we examined the allele and diplotype frequencies across 5 major ethnic groups present in these populations namely, Indonesians, Chinese, Malays, Indians and Caucasians.

Methods – Human gDNA samples, extracted from the buccal swabs of 246 participants, were tested on Nala PGx Core™ and two chosen benchmarks, Agena VeriDose® Core and *CYP2D6* Copy Number Variation (CNV) Panel, and TaqMan® DME Genotyping Assays. Performance was evaluated based on assay robustness, precision and accuracy at the genotype- and diplotype-level.

Results – Nala PGx Core™ demonstrated high genotype- and diplotype-level call rates of >97% and >95% respectively in *CYP2D6*, and 100% for *CYP2C9*, *CYP2C19* and *SLCO1B1*. A precision rate of 100% was observed on both intra- and inter-precision studies. Variant-level concordance to the benchmark methods was ≥96.9% across all assays, which consequently resulted in a diplotype-level concordance of ≥94.7% across *CYP2C9*, *CYP2C19* and *CYP2D6*. Overall, the allele frequencies of *CYP2D6*10* and *CYP2D6*36* were higher in our cohort as compared to previous records. Notably, *CYP2D6* copy number variation (CNV) analysis demonstrated a *CYP2D6* *10/*36 frequency of 26.5% amongst the Indonesian cohort.

Conclusion –Nala PGx Core™ produced robust and accurate genotyping when compared to other established benchmarks. Furthermore, the panel successfully characterized alleles of clinical relevance in the Singaporean and Indonesian populations such as *CYP2D6*10* and *CYP2D6*36*, suggesting its potential for adoption in clinical workflows regionally.

Introduction

Pharmacogenomics (PGx) is a branch of medicine concerned with determining the response of an individual to therapeutic drugs using genetic and/or genomic information[1]. With up to 70% of adverse drug reactions (ADRs) having high genetic associations[2], and the sunk cost of trial-and-error prescriptions amounting to USD 30 billion[3], the clinical utility[4] of PGx appears to be gaining prominence.

Applications of PGx include the genotyping of Cytochrome P450 (P450) enzymes which are significantly involved in drug metabolism and chemical toxicity[5]. *CYP2C9*, *CYP2C19* and *CYP2D6* display common polymorphisms that produce altered enzyme activity, often resulting in deviant drug metabolism that leads to side effects from drugs metabolized by them[5].

Alterations in *CYP2C9* can disrupt the metabolism of warfarin, while *CYP2C19* is associated with the metabolism of a number of drugs including clopidogrel, omeprazole and phenytoin[6,7]. The highly polymorphic *CYP2D6* has more than 100 variants and is responsible for the metabolism of approximately 25% of all clinically used drugs, including codeine, fluoxetine and amitriptyline[7]. For this reason, pharmaceuticals are particularly cautious in the development of drugs that are known to interact with these three P450s[5]. Additionally, pharmacogenes, such as *SLCO1B1*, are responsible for encoding transporters of simvastatin and other statins into tissues also affect their response upon intake in individuals. Variants of this gene are associated with increased risk of muscle pain (myalgia) and damage, including myopathy and in severe cases rhabdomyolysis[8]. Previous studies suggest the role of specific *CYP2C19* and *SLCO1B1* variants in the bioactivation of drugs such as clopidogrel and atorvastatin in the Singaporean population[9,10]. The *CYP2C19* variant, rs4986893, which is implicated in reduced clopidogrel metabolism, has been observed to be 50 times more prevalent in the Singaporean Chinese population than in Europeans[10]. The *SLCO1B1* variant, rs4149056, which is implicated in statin metabolism, has been observed to occur less frequently in the Singaporean population[9]. Taken together, these cases highlight the need to harness PGx testing to account for population differences in the personalization of prescriptions[11].

Current methods on PGx testing for the identification of genetic polymorphisms revolve around variant genotyping that utilize technologies ranging from Next Generation Sequencing (NGS), Microarray, Mass Spectrometry to Quantitative PCR (qPCR)[1,6,12,13]. Main considerations in the adoption of a platform include its robustness, effectiveness and cost-saving, especially in localities with limited resources. qPCR-based assays satisfy these criteria and are a preferred platform for clinical laboratories[14–19]. However, some of the available commercial kits are limited in their ability to test the 4 genes of interest mentioned above in a single panel[20–25]. Nala PGx Core™ is a qPCR-based multi-gene panel consisting of 20 pharmacogenomic variants that are associated with altered *CYP2C9*, *CYP2C19*, *CYP2D6* and *SLCO1B1* activity in Asian geographies. Our study aims to evaluate the performance of Nala PGx Core™ in effectively identifying genetic variations that may contribute to PGx-related clinical outcomes in Singapore and Indonesia, with a secondary objective of highlighting the allele and diplotype frequencies in the geographies examined.

Methods and Materials

Ethics Approval

Institutional Review Board (IRB) approval was granted by the Parkway Independent Ethics Committee (Singapore) under IRB Reference Number PIEC/2019/021 and Siloam Hospitals Ethics Review Committee (Jakarta, Indonesia) under IRB Reference Number 001/EA/KEPKK/RSMRCCC/V/2019.

Study Recruitment

Patients were recruited on behalf of Nalagenetics Pte. Ltd. with written informed consent forms from recruitment sites in Singapore and Indonesia. A total of 251 samples were evaluated from 5 major ethnic groups to ensure the representation of the major ethnic groups residing in both countries – Chinese, Malays, Indians, Caucasians and Indonesians. Participants identifying as one or more of the following ethnicities were categorized as Indonesians: Ambon, Batak, Betawi, Jawa, Lampung, Manado, Minangkabau, Nusa Tenggara Timur, Palembang, Sulawesi, Sunda, Timor Leste, Tolaki and Toraja.

Buccal samples were collected using OraCollect (Cat No. DNA OCR-100 from DNA Genotek) and genomic DNA (gDNA) extracted using the Monarch Genomic DNA Purification Kit (Cat No. T3010 from NEB). The extraction procedure followed manufacturer's instructions with additional dry-spin step at maximum speed for 1 minute after the 2nd buffer washing step. The quality and concentration of gDNA extracts were quantified by NanoDrop 2000 Spectrophotometer (Singapore) and BioDrop-µLITE (Indonesia). Samples that failed to meet the DNA quality control criteria (n=5) of A260/280 >1.7 and DNA yield >500ng were excluded from the study. The remaining extracted gDNA samples (n=246) were stored at -20□ for downstream application.

Nala PGx Core™

The Nala PGx Core™ kit from Nalagenetics Pte. Ltd. consists of 20 qPCR-based variant assays across four genes – *CYP2C9*, *CYP2C19*, *CYP2D6* and *SLCO1B1*. Whilst assays for *CYP2C9*, *CYP2C19* and *CYP2D6* have been designed to enable the detection of specific star alleles, the *SLCO1B1* assay has been designed to detect the variant rs4149056, which is present in three reduced function haplotypes namely, *SLCO1B1*5*, *SLCO1B1*15* and *SLCO1B1*17*. The *SLCO1B1* assay is thus, unable to differentiate between each of the three aforementioned haplotypes. The variants covered by the kit are outlined in Table 1.

Assays were set up on a 96-well plate. Human gDNA was added at a concentration of 2 ng/µL as template for the qPCR reaction, which was then performed on the Bio-Rad CFX96 IVD Touch™ Real-Time PCR Detection System per the product insert. Run analysis was performed using the application CFX Manager 3.1 or CFX Maestro, and exported as raw .csv files. Exported files were uploaded into the companion software, Nala Clinical Decision Support™ (Nala CDS™) for further analysis of variant genotyping, diplotype determination and phenotype

translation. Genotyping using Nala PGx Core™ was performed at the Molecular Diagnosis Centre, National University Health System, Singapore (NUHS MDC) and PT Nalagenetik Riset Indonesia.

Agena VeriDose® Core and *CYP2D6* Copy Number Variation (CNV) Panel

The VeriDose® Core and *CYP2D6* Copy Number Variation (CNV) Panel from Agena Bioscience® consists of 68 variant assays in 20 genes and 5 *CYP2D6* CNV assays, accompanied by a reporting software that automatically analyzes each variation[26]. Genotyping using Agena VeriDose Core and *CYP2D6* CNV Panel was performed at the Genome Institute of Singapore. Variants evaluated using this platform are listed in Table 1. The Agena VeriDose® Panel has been utilized by the United States Centers for Disease Control and Prevention (CDC) as part of their Genetic Testing Reference Material (GeT-RM) Coordination Program[27].

TaqMan® Drug Metabolism Enzyme (DME) Genotyping Assay

TaqMan® DME Genotyping Assays were utilized in the evaluation of *CYP2D6* rs769258 (TaqMan Assay ID AH21B9N) and *CYP2D6* rs267608319 (TaqMan Assay ID C__27102444_F0). Assays were set up on a 384-well plate[28] with a sample input of human gDNA at 2 ng/µL. The subsequent PCR reaction was performed on the Applied Biosystems ViiA™ 7 Real-Time PCR System as per the recommended cycling conditions, at the Genome Institute of Singapore. Post-PCR plate read was performed using the companion software, TaqMan® Genotyper™ Software for single nucleotide polymorphisms (SNP) genotyping. Similar to the Agena VeriDose® Panel, TaqMan® DME Genotyping Assays were employed in the characterization of DNA samples as part of the CDC GeT-RM program[27].

Robustness

Genotype- and diplotype-level call rates were defined as the percentage of samples that returned a genotype at the variant-level or were assigned a distinct diplotype for the gene of interest, respectively. Failed tests were defined as samples that did not return a genotype and/or diplotype call for the genes evaluated.

$$\text{Call Rates, } \% = \frac{\text{Total Sample Size-Failed Tests}}{\text{Total Sample Size}} \times 100\%$$

Precision

Three samples at 3 DNA concentrations were tested across 3 reagent lots on 2 machines. Each test condition was repeated within the same plate for a triplicate. For variant assays that identified SNPs and indels, intra-precision was performed within the same plate, run as triplicates across 47 tests. Inter-precision was assessed from 120 tests performed across plate runs covering the 4 variables – samples, DNA concentration, reagent lots and machines. Concordance rates across precision studies were calculated as the percentage of tests that returned a genotype call concordant to the expected truth for each variant assay. Discordant genotype was defined as instances when the test returned a genotype call that was different from the expected truth.

$$\text{Concordance Rate, \%} = \frac{\text{No. Of Tests Performed} - \text{No. Of Tests With Discordant Genotype}}{\text{No. Of Tests Performed}} \times 100\%$$

For *CYP2D6* CNV assays, copy number estimates for Intron 2 and Exon 9 of the three samples were derived based on their cycle threshold (Ct) results across plate runs.

$$\text{Copy Number} = 2 \times 2^{-\Delta\Delta Ct}$$

$$\Delta\Delta Ct = \left(Ct_{\text{reference gene calibrator}} - Ct_{\text{CYP2D6 calibrator}}\right) - \left(Ct_{\text{reference gene}} - Ct_{\text{CYP2D6 sample}}\right)$$

Testing of the three samples was repeated for a number of plate runs, n (Table 5), and calculated for the average copy number of each sample and their coefficient of variation (CV). The CV for each plate run was calculated by finding the standard deviation (σ_{plate}) between triplicates within the same plate run, and divided by the triplicate mean (μ_{plate}). The average of the individual CVs was reported as the intra-precision CV. For inter-precision CV, standard deviation population ($\sigma_{plate\ means}$) was divided by the mean population, i.e. average of means.

$$\text{Intra- CV,\%} = \frac{\sum_n \frac{\sigma_{\text{plate}}}{\mu_{\text{plate}}}}{n} \times 100\%$$

$$\text{Inter- CV,\%} = \frac{\sigma_{\text{plate means}}}{\sum_n \mu_{\text{plate}} / n} \times 100\%$$

Accuracy

Variant-level Concordance

The accuracy of Nala PGx Core™ in genotyping at a variant-level was evaluated by comparing calls produced by Nala PGx Core™ assay against benchmark methods as listed in Table 1. Samples that successfully produced genotype calls for all variants tested on Nala PGx Core™ and its benchmarks were considered for the evaluation (n = 225 for all variants except *CYP2D6* CNV; n = 224 for *CYP2D6* CNV). Samples that failed to produce a genotype call on one or more of the platforms were excluded from the concordance calculation (n = 21 for all variants except *CYP2D6* CNV; n = 22 for *CYP2D6* CNV, Supplementary Table 7). Discordant calls were defined as instances in

which Nala PGx Core™ provided a genotype call that was different from that of a call made by the corresponding benchmark. Percentage concordance to the benchmark was calculated per variant as follows –

$$\text{Concordance To Benchmark Per Variant, \%} = \frac{\text{Total Sample Size - Discordant Calls By Nala PGx Core™}}{\text{Total Sample Size}} \times 100\%$$

Diplotype-level Concordance

The accuracy of Nala PGx Core™ in assigning a diplotype call for *CYP2C9, CYP2C19,* and *CYP2D6*, was evaluated by comparing calls against the Agena VeriDose® Core and *CYP2D6* CNV Panel. Samples that met the following criteria were included in the sample size of each gene:

1. Successful genotype-level calls on the relevant platforms for all variants covered by the gene of interest
2. Successful assignment of a diplotype for the gene of interest on both Nala PGx Core™, and Agena VeriDose® Core and *CYP2D6* CNV Panel

Discordant calls were defined as instances in which Nala PGx Core™ assigned a diplotype that differed from the call made by the Agena VeriDose® Core and *CYP2D6* CNV Panel.

$$\text{Concordance, \%} = \frac{\text{Total Sample Size - Discordant Calls By Nala PGx Core™}}{\text{Total Sample Size}} \times 100\%$$

Frequencies By Ethnicity

Ethnicities were obtained based on participant self-identification across both the population cohorts as part of the recruitment questionnaire. Participants that did not report an ethnic group in the recruitment form were excluded from the frequency analysis. The following were further excluded from the frequency analysis:

1. Samples in which participants did not report an ethnic group on the recruitment form (n=6)
2. Samples with one or more variant level failures across the 4 genes evaluated in Table 1 (n=18)
3. Samples with one or more diplotype-level failures ("No Call") across *CYP2C9, CYP2C19,* and *CYP2D6* on Nala PGx Core™ and the Agena VeriDose® Core and *CYP2D6* CNV Panel (n=15)
4. Samples with discordant diplotype calls for the gene of interest (n=variable, Supplementary Table 7)

The remaining samples were included in the allele-level frequency analysis of *CYP2C9* (n=206), *CYP2C19* (n=201), *CYP2D6* (n=195) and *SLCO1B1* (n=203), as well as in the diplotype-level frequency analysis of *CYP2C9* (n=206), *CYP2C19* (n=201) and *CYP2D6* (n=195). Allele and diplotype frequency values were derived using the following formulae[29,30], for both the overall study cohort as well as for each ethnic group.

$$\text{Frequency Of Allele 'X' In A Given Population} = \frac{\text{Total Copies Of Allele 'X'}}{\text{Total Copies Of All Alleles For The Gene Of Interest}}$$

$$\text{Frequency Of Diplotype 'X' In A Given Population} = \frac{\text{Total Instances Of Diplotype 'X'}}{\text{Total Number Of Individuals In The Population}}$$

Results

Robustness

We first sought to evaluate the observed genotype- and diplotype-level call rates of the platforms evaluated in this study. 246 samples underwent variant genotyping and diplotype determination, across the four genes evaluated on the genotyping platforms (Tables 2, 3). The genotype-level call rates for Nala PGx Core™ were at 100% for *CYP2C9*, *CYP2C19* and *SLCO1B1*, and the diplotype-level call rates were at 100% for *CYP2C9* and *CYP2C19*. The benchmark platform, Agena VeriDose® Core Panel, demonstrated call rates of >95.9% at the genotype-level and >90.7% at the diplotype-level.

Most variants in *CYP2D6*, except for seven, achieved 100% call rates on Nala PGx Core™, while the corresponding call rates of the benchmark platforms were observed to be between 95.9 – 99.2% on Agena VeriDose® Core and *CYP2D6* CNV Panel, and 100% on TaqMan® DME Genotyping Assays. Out of the seven aforementioned variants, Nala PGx Core™ demonstrated higher call rates than the benchmark for the genotyping of rs1065852, Intron 2 and Exon 9 variants. For rs3892097, rs769258, rs5030865, and rs267608319, the accompanying benchmarks demonstrated higher call rates. At the diplotype-level, Nala PGx Core™ demonstrated a CYP2D6 call rate of 95.9% as compared to the benchmark, which was observed to be at 90.7% (Table 3).

Precision

A precision study was conducted to assess the consistency of Nala PGx Core™ for samples tested under the same conditions (intra-precision) and under different conditions (inter-precision). Both study resulted in 100% concordance for all assays across replicates, demonstrating consistent genotyping results across a range of DNA concentration, reagent lots and machine variations (Table 4). Precision of *CYP2D6* CNV assay was reported as the average copy number obtained for Intron 2 and Exon 9 of three samples, and their CV calculated across the test conditions (Table 5). The intra- CV ranged from 3-6% while inter- CV between 5-13%, demonstrating high precision of the assays across variables, where acceptable ranges were intra- CV below 10% and inter- CV below 15%[31].

Accuracy

Variant-level Concordance

To assess the accuracy of the panel, 18 SNPs and 2 *CYP2D6* Copy Number assays were genotyped on the panel, Nala PGx Core™, against benchmark methods as listed in Table 1. The 225 sample cohort consisted of DNA samples isolated from buccal swabs that had successfully produced genotype calls for all variants tested on Nala PGx Core™ and its benchmarks. The sample size per genotype displayed in Table 6 refers to the genotype calls made by the benchmark.

11 variants (*CYP2C9* rs1799853, rs1057910; *CYP2C19* rs12248560; *CYP2D6* rs5030655, rs3892097, rs35742686, rs28371725, rs769258, rs5030656, rs59421388, rs267608319) were genotyped against Agena VeriDose® Core with a resulting concordance rate of 100% (N = 225 samples). Discordance was observed for *CYP2C19* rs4244285 (n=7), *CYP2C19* rs4986893 (n=3), *CYP2D6* rs1065852 (n=1), *CYP2D6* rs16947 (n=7), *CYP2D6* rs1135840 (n=5), *CYP2D6* rs5030865 (n=1) and *SLCO1B1* rs4149056 (n=6), with a mismatch rate of 0.44% to 3.1% for the affected assays. Overall, Nala PGx Core™ demonstrated >96% concordance to the benchmark, Agena VeriDose® Core, for the 16 variants across 225 samples (Table 6).

Variants not present on Agena VeriDose® Core, *CYP2D6* rs769258 and *CYP2D6* rs267608319, were genotyped using TaqMan® DME Genotyping Assays. Nala PGx Core™ demonstrated 100% concordance (N = 225) to the benchmark for both SNPs.

For the *CYP2D6* Intron 2 and Exon 9 Copy Number assays, concordance was observed to be at 99.6% and 98.7% respectively, against the Agena *CYP2D6* CNV Panel. Discordant calls were observed in samples with an Intron 2 copy number greater than 3 (n=1), and for samples with an Exon 9 copy number of one (n=1) and two (n=2). The sample size per copy number displayed in Table 7 refers to the copy number calls made by the benchmark.

A summary of the concordance percentage as well as the distribution of genotypes of each variant are displayed in Table 6. Similarly, the distribution of *CYP2D6* Intron 2 and Exon 9 copy numbers are displayed in Table 7.

Diplotype-level Concordance

Following successful genotyping at the variant level, we investigated the accuracy of Nala PGx Core™ in assigning a diplotype call for *CYP2C9*, *CYP2C19* and *CYP2D6*, with reference to the Agena VeriDose® Core and *CYP2D6* CNV Panel. Table 8 displays the percentage concordance after the further exclusion of samples that demonstrated diplotype mismatches arising from technological differences, where technological differences refer to the varying allele coverage of each platform (Supplementary Table 7). These differences were derived from the variant lists of both Nala PGx Core™ (Table 1) and its benchmark, the Agena VeriDose® Core and *CYP2D6* CNV Panel[26].

Overall, a percentage agreement of 100% for *CYP2C9* (n=221), 96.4% for *CYPC219* (n=223) and 94.7% for *CYP2D6* (n=209) was observed between Nala PGx Core™ and the benchmark. Discordance was observed at n=1 for all diplotypes listed in Table 8 except for the following with more than one discordant calls: *CYP2C19* *2/*2 (n=4), and *CYP2D6* *4/*36 (n=2).

Frequencies By Ethnicity

For samples that were concordant on Nala PGx Core™ and the benchmark platforms, we were able to observe the allele frequencies amongst the populations residing in Singapore and Indonesia (Table 9). From the combination of alleles present in individual's chromosome, we were able to observe both the diplotype and corresponding phenotype frequencies amongst our study population (Table 10).

For *CYP2C9*, *3 allele was the most common amongst Chinese and Malay, and *2 allele amongst Caucasian, which is in line with PharmGKB's reported distribution for the East Asian and European populations respectively. Our study also reported *3 allele as the more common variant in Indian population than *2, as opposed to PharmGKB's frequency. These allele frequencies translated to *1/*3 as a common diplotype observed in Chinese, Malay and Indians, and *1/*2 in Caucasians.

For *CYP2C19*, we observed highest frequency of *CYP2C19*2* amongst Chinese, Malay and Indonesian which were categorized as East Asian populations. This resulted into high frequency of *1/*2 heterozygous depicted as a common diplotype amongst the population. The alleles *2 and *17 were observed as the common variants at equal proportions of 0.229 in Indians and 0.138 in Caucasians. *CYP2C19*3* was a common minor allele least observed amongst Indians and Caucasians, 0 and 0.017 respectively. As a result, *1/*2 and *1/*17 were common diplotypes observed in Indian and Caucasian populations, and *2/*17 only seen in Indians.

Common polymorphisms of *CYP2D6* in our population were seen in *10 and *36 alleles, at almost two-fold higher frequencies in Chinese, Malay and Indonesian than Indians. We noticed high frequencies of *36 in our East Asian population. Additionally, two functional copies of *36 allele were present in 1.4% of Chinese population who participated in our study (Figure 1). These alleles resulted in high frequency of *10/*36 as common diplotype amongst Chinese, Malay and Indonesian population. Our Indian population observed equal distribution of alleles *2, *10 and *36, although PharmGKB reported only *2 as the highest frequency in South Asians. The corresponding common diplotypes observed in Indians were of equal proportions in *1/*2, *1/*36 and *1/*10 ranging from 0.12 to 0.16. The alleles *2 and *4 were most common amongst Caucasians as reported by PharmGKB in Europeans, resulting in common diplotypes of *1/*2 and *1/*4 in the population.

For *SLCO1B1*, the frequencies of rs4149056 across all ethnicities were consistent with values reported in gnomAD, with the variant being most common amongst Caucasians (0.167) and least amongst Indians (0.040). The frequency amongst East Asians (0.125, gnomAD), as denoted by the Chinese and Indonesian ethnic groups in this study, ranged between 0.074 and 0.125 respectively.

Discussion

In this study, we evaluated the performance of Nala PGx Core™, a qPCR-based panel that evaluates 18 variants and 2 *CYP2D6* Copy Number markers across 4 pharmacogenes with established relevance across major ethnic groups in Singapore and Indonesia population. Nala PGx Core™ comes coupled with a reporting software that supports variant detection, diplotype assignment, diplotype-to-phenotype translation and the generation of reports containing clinical recommendations for each phenotype. The panel demonstrated high genotype-level call rates of >97% for *CYP2D6*, and 100% for *CYP2C9*, *CYP2C19* AND *SLCO1B1*. Similarly, high diplotype-level call rates were observed at >95% for *CYP2D6*, and 100% for *CYP2C9* and *CYP2C19*. A precision of 100% was observed under the

same conditions (intra) and across different conditions (inter). In comparison to other established platforms serving as benchmarks during the study, Nala PGx Core™ had ≥96.9% concordance rate for all variant level assays, which consequently resulted in ≥94.7% concordance at a diplotype level across *CYP2C9*, *CYP2C19* and *CYP2D6*.

Failures to produce a variant genotype call could be attributed to several reasons. Firstly, failures could potentially stem from the quality of gDNA, despite the DNA quality checks (QC) performed prior to accepting a sample for testing. Poor DNA quality could arise from multiple factors along the sample handling chain. Such factors include the contamination of the buccal fluid by interfering particles during sample collection, inconsistent conditions during sample transport and human error during sample purification. These may lead to the degradation of genomic DNA, poor homogenization of the sample in collection and/or extraction buffers, and the carryover of contaminants, thereby compromising sample integrity[32]. Further QC that involves specific quantification of double-stranded non-fragmented DNA and traces of other interfering materials like RNA, carryover carbohydrate, residual phenol, guanidine or other reagents could enhance the call rate[33]. Regardless, the overall higher variant call rates on Nala PGx Core™ panel demonstrate high tolerance of interfering substances, therefore alluding to the high robustness of the assay. Often, failures at variant genotyping subsequently contribute to failures at determining diplotype, since an incomplete variant panel cannot translate into a diplotype. Failures at diplotype calling could also arise from a combination of variants that do not map onto a distinct diplotype, per the reference database, potentially indicating a novel combination.

We further sought to evaluate the allele frequency distribution in the study cohort across the 5 major ethnic groups observed (Indonesian, Chinese, Malay, Indian and Caucasian). The data presented was limited strictly to the geographical boundaries of Singapore and Indonesia, which could account for the difference in allele frequencies observed in comparison to PharmGKB, which is representative of a more expansive and global cohort[34]. Whilst dissimilar to database figures, our study demonstrated the distributions for the following to be concordant with previous studies[7,35,36], suggesting a niche in the PGx landscape of Singapore and Indonesia –

1. *CYP2C9*3* allele as the more common variant within Indians than *CYP2C9*2*[7]
2. A *SLCO1B1* rs4149056 frequency of 12.5% amongst Indonesians[35]
3. High frequencies of the *CYP2D6*10* amongst Indonesians[35]
4. High frequencies of the *CYP2D6*36* allele as seen in the Indonesian, Chinese and Malay ethnicities[36]
5. Two functional copies of *CYP2D6* within our Chinese population[36]

Due to the lack of *CYP2D6* copy number references[35], it is our understanding that the frequency of *CYP2D6*36* in Indonesia may not be well-represented. Our study revealed that the prevalence of *CYP2D6*36* to be approximately seventeen times higher amongst Indonesians as compared to the corresponding East Asian allele frequency on PharmGKB[37]. Furthermore, our study provides insight on the frequency of the *CYP2D6* *10/*36 diplotype in the archipelago, which may help inform the adoption of population-specific PGx workflows in the region. Taken together, the data presents a case for extending tailored PGx testing across the 4 pharmacogenes studied, *CYP2C9*, *CYP2C19, CYP2D6* and *SLCO1B1*, in South East Asia.

Limitations

The single largest reason for the diplotype-level discordance observed between Nala PGx Core™ and the Agena VeriDose® Core and *CYP2D6* CNV Panel appears to be a difference in the technological offerings and hence, allele coverage of each panel. From Supplementary Table 7, out of the 28 instances of discordance observed, 9 instances were attributed to this cause (32.1%). This included two alleles each in *CYP2C9*, *CYP2C19* and *CYP2D6*.

The variants *CYP2C9*12*, *CYP2C9*13*, *CYP2C19*4A*, *CYP2C19*6* and *CYP2D6*13* were covered by Agena VeriDose® Core but not by Nala PGx Core™. Due to lack of coverage for these alleles, the genotypes identified by Nala PGx Core™ were inconsistent with the calls produced by Agena VeriDose® Core. It is important to note that Nala PGx Core™ was curated specifically to include alleles that were relevant to Asian and European populations, with a Minor Allele Frequency (MAF) >1% based on PharmGKB database for East Asians, South Asians and Europeans[37]. Similarly, *CYP2D6*35*, an allele present in 5.5% of Europeans and 1.2% of South Asians, was identified by Nala PGx Core™ but not by Agena VeriDose® Core. The technological differences and subsequent inconsistencies in reporting suggest the need for further review from a product development standpoint.

For the highly polymorphic *CYP2D6* gene, Nala PGx Core™ was designed to only cover the variant alleles listed in Table 1, that could lead to overestimation of *1 allele in our population. This means star alleles that may be present in the population were identified as normal genotype, which could result in overestimation of *1 allele in our population as compared to the PharmGKB's reported frequency (Supplementary Table 4).

The study also relied on self-reported ethnicity, which may have contributed to racial bias in summarizing the observed allele and diplotype frequencies per ethnic group. Future studies may consider screening the ethnicities of participants as well as their next-of-kin, up to two generations prior[10], to improve classification accuracy.

Finally, the study cohort consisted of 246 individuals, with each ethnic group consisting of approximately 24 to 75 individuals for the frequency analysis. Larger scale studies may be conducted to ensure that the trends observed as part of this study may be generalized across the populations examined.

Future Work

Further investigation is required for the remaining samples that had discrepant genotypes across platforms. Nala PGx Core™ was designed as a qPCR platform and genotyping was accompanied by Nala CDS™ that utilized quantitative thresholds. There could be cases of samples displaying borderline or ambiguous qPCR amplification curves and Ct-values, which could be misinterpreted by these thresholds. The benchmark platforms, Agena VeriDose® Core and *CYP2D6* CNV Panel and TaqMan® DME Genotyping Assays, were also analyzed by their accompanying software packages. Such ambiguous cases on either platform could lead to instances of discordance and sequencing of the region of interest may be required to ascertain the truth. For gene variants caused by SNPs and indels, the qPCR amplified product can be submitted for genome sequencing[13]. In the investigation of copy

number variants, a two-step approach can be adopted[38]. Firstly, CNV calls observed in this study may be checked against an alternative benchmark such as digital droplet PCR (ddPCR)[39]. Secondly, where discordance in CNV calling persists, methods such as XL-PCR can be adopted to identify the presence of *CYP2D6/CYP2D7* hybrid states, with submitting samples for whole-genome sequencing[38] being an option. Investigation of copy number variants may require amplification of region spanning across the gene of interest.

Conflict of Interest

†"Sample Size Per Genotype" reflects the counts of each genotype as produced by the benchmark, and not by Nala PGx Core™.
‡Refer to Table 1 for an outline of the benchmark methods used per variant.
§Discordant calls refer to instances in which Nala PGx Core™ did not produce a genotype call concordant with the benchmark.

Table 7 Genotype concordance for *CYP2D6* Intron 2 And Exon 9 Copy Number Variations

Gene	Variant	Copy Number	Sample Size Per Copy Number†	Concordance to Benchmark, %‡	Discordant Calls By Nala PGx Core™§
CYP2D6	**Intron 2**	0	0	99.6	0
	N = 224	1	12		0
		2	130		0
		>=3	82		1
	Exon 9	0	0	98.7	0
	N = 224	1	24		1
		2	193		2
		>=3	7		0

†"Sample Size Per Copy Number" reflects the counts of each copy number call as produced by the benchmark, and not by Nala PGx Core™
‡Refer to Table 1 for an outline of the benchmark methods used per variant.
§Discordant calls refer to instances in which Nala PGx Core™ did not produce a copy number call concordant with the benchmark.

Table 8 Diplotype concordance for *CYP2C9*, *CYP2C19* and *CYP2D6* between Nala PGx Core™, and Agena VeriDose® Core and *CYP2D6* CNV Panel

Genes	Concordance, %†	Discordant Diplotypes		
		Agena VeriDose® Core and *CYP2D6* CNV Panel	Nala PGx Core™	Instances
CYP2C9	100% (n = 221)	NA	NA	NA
CYP2C19	96.4% (n = 223)	*1/*1	*1/*3	1
		*1/*2	*1/*1	1
		*1/*2	*1/*3	1
		*1/*3	*2/*2	1
		*2/*2	*1/*1	2
		*2/*2	*1/*2	2
CYP2D6	94.7% (n = 209)	*1/*1	*2/*2	1
		*1/*10	*1/*10, CN >=3	1
		*1/*41	*39/*41	1
		*2/*2	*1/*1	1

		*2/*10	*1/*10	1
		*2/*36, CN >=3	*2/*10, CN >=3	1
		*4/*36	*4/*10	2
		*10/*36	*2/*36	1
		*13 *1/*10	*1/*10, CN >=3	1
		*13 *1/*41, CN = 1	*1/*41	1

†The concordance presented in this table excludes samples that have mismatches in diplotype calls arising from technological differences between platforms. Please refer to Supplementary Table 7 for a detailed breakdown of all diplotypes detected.

Table 9 Observed allele frequencies by ethnicity

Gene	Allele or Variant	Allele Frequencies (Per This Study)						Allele Frequencies (PharmGKB)
