14 **ABSTRACT**

15 The emergence of the novel coronavirus pneumonia (Covid-19) pandemic at the end of 2019 led to chaos
16 worldwide. The world breathed a sigh of relief when some countries announced that they had obtained the
17 appropriate vaccine and gradually began to distribute it. Nevertheless, the emergence of another wave of
18 this disease has returned us to the starting point. At present, early detection of infected cases has been
19 the paramount concern of both specialists and health researchers. This paper aims to detect infected
20 patients through chest x-ray images. The large dataset available online for Covid-19 (COVIDx) was used
21 in this research. The dataset consists of 2,128 x-ray images of Covid-19 cases, 8,066 normal cases, and
22 5,575 cases of pneumonia. A hybrid algorithm was applied to improve image quality before conducting
23 the neural network training process. This algorithm consisted of combining two different noise reduction
24 filters in the images, followed by a contrast enhancement algorithm. In this paper, for Covid-19 detection,
25 a novel convolution neural network (CNN) architecture, KL-MOB (Covid-19 detection network based on
26 MobileNet structure), was proposed. KL-MOB performance was boosted by adding the Kullback–Leibler
27 (KL) divergence loss function at the end when trained from scratch. The Kullback–Leibler (KL) divergence
28 loss function was adopted as content-based image retrieval and fine-grained classification to improve
29 the quality of image representation. This paper yielded impressive results, overall benchmark accuracy,
30 sensitivity, specificity, and precision of 98.7%, 98.32%, 98.82%, and 98.37%, respectively. The promising
31 results in this research may enable other researchers to develop modern and innovative methods to aid
32 specialists. The tremendous potential of the method proposed in this research can also be utilized to
33 detect Covid-19 quickly and safely in patients throughout the world.

34 **INTRODUCTION**

35 The novel coronavirus 2019 (Covid-19) is a recently recognized disease caused by severe acute respiratory
36 syndrome coronavirus 2 (SARS-CoV-2). Being highly transmissible and life-threatening, it has rapidly
37 turned into a global pandemic, affecting worldwide health and well-being. Tragically, no effective
38 treatment has yet been approved for patients with Covid-19. But the patient can have a good chance of
39 survival if they are diagnosed early enough.

40 As a widely available, time- and cost-effective diagnosing tool, Chest X-ray (CXR) can potentially
41 be used for the early recognition of Covid-19. Nevertheless, Covid-19 can share similar radiographic
42 features with other types of pneumonia, making it difficult for radiologists to distinguish manually. With
43 such a difficulty, manual detection of Covid-19 becomes time-consuming and mistake-prone as it is left to
44 the intuitive judgment of the radiologist. As such, it is highly recommended to adopt automated detection

45 techniques.

46 With the rapid spread of Covid-19 globally, researchers have begun using state-of-the-art DL tech-
47 niques for the automated recognition of Covid-19. The initial lack of Covid-19 data compelled earlier
48 research to use pre-trained networks to build their own models (Narin et al., 2020; Ozturk et al., 2020;
49 Apostolopoulos and Mpesiana, 2020; Civit-Masot et al., 2020; Albahli, 2020; Sethy and Behera, 2020;
50 Apostolopoulos et al., 2020; Chowdhury et al., 2020; Punn and Agarwal, 2020; Farooq and Hafeez, 2020;
51 Maghdid et al., 2020; Hemdan et al., 2020). Just a few months after being discovered, Covid-19 had
52 infected millions of peoples worldwide. Consequently, a mid-range dataset of positive cases has been
53 made available for public use, which was uploaded from [https://github.com/lindawangg/
54 COVID-Net/blob/master/docs/COVIDx.md](https://github.com/lindawangg/COVID-Net/blob/master/docs/COVIDx.md) by (Wang et al., 2020). This, in turn, has enabled
55 further progress in developing new, accurate, in-depth models for Covid-19 recognition (Ahmed et al.,
56 2020; Afshar et al., 2020; Ucar and Korkmaz, 2020; Luz et al., 2020; Hirano et al., 2020; Rezaul Karim
57 et al., 2020). However, some medical imaging issues usually pose difficulties in the recognition task,
58 reducing the performance of these models. These issues include, but are not limited to, insufficiency
59 of training data, inter-class ambiguity, intra-class variation, and visible noise. These problems indeed
60 necessitate a significant enhancement of the discrimination capability of the associated model.

61 One way around these issues is to utilize proper image-preprocessing techniques for noise elimination
62 and contrast enhancement. A close look at the available images reveals the presence of various types
63 of noise, such as impulsive, Poison, speckle, and Gaussian noise. See Figure 1 (the most common
64 types of noise in X-ray images (Paul et al., 2018)). However, the most prevalent studies have been
65 dedicated to only some of these types of noise, e.g., Gaussian and Poison. In particular, among many other
66 techniques, histogram equalization (HE)) (Civit-Masot et al., 2020; Tartaglione et al., 2020), adaptive
67 total variation method (Punn and Agarwal, 2020), Contrast Limited Adaptive Histogram Equalization
68 (CLAHE) (El-bana et al., 2020; Saiz and Barandiaran, 2020; Maguolo and Nanni, 2020), white balance
69 followed by (Siddhartha and Santra, 2020), intensity normalization followed by CLAHE (Horry et al.,
70 2020; El Asnaoui and Chawki, 2020), histogram equalization (HE), Perona-Malik filter (PMF), unsharp
71 masking (Rezaul Karim et al., 2020), and Gaussian filter (Jamil et al., 2020) are, as far as we are aware,
72 the only adopted techniques in Covid-19 recognition to date. Moreover, the utilized filters can result in
73 blurry (by Gaussian filter) or blocky (by PMF) features in the processed image. Accordingly, there is still
room to incorporate more effective preprocessing techniques to further increase the system's accuracy.

Figure 1. Noisy images: a) image with impulsive noise and b) image with Gaussian noise.

74
75 Motivated by the outstanding results in the previously mentioned works as well as the need for
76 close-to-perfect recognition models, this paper integrates novel image-preprocessing enhancement with
77 deep learning to meet the challenges arising from data deficiency and complexity. Specifically, we
78 combine adaptive median filter (AMF) and Non-Local Means filter (NLMF) to remove the noise from
79 the images. Indeed, many works have analyzed the performance of these two filters in X-ray imagery
80 denoising, e.g., (Kim et al., 2020; Raj and Venkateswarlu, 2012; Rabbouch et al., 2020; Sawant et al.,
81 1999; Mirzabagheri, 2017), demonstrating their superiority to various filters including the ones in the cited
82 works in terms of removing impulsive, Poison, and speckle noise while preserving the useful image details.
83 We then utilize the CLAHE approach to enhance the contrast of the denoised images. The enhanced
84 images are finally fed into a Mobile CNN for training and validation phases. The motivation behind
85 choosing Mobile CNN is that it not only helps to reduce overfitting but also runs faster than regular CNN
86 with many fewer parameters (Howard et al., 2017; Yu et al., 2020). Inspired by (Alfasly et al., 2019;

87 Alghaili et al., 2020) we adopt the KL divergence loss to measure how far we are from the optimal solution
88 during the iterations. We evaluated the performance of the proposed framework on the COVIDx dataset
89 in terms of a wide variety of metrics: accuracy, sensitivity, specificity, F1-score, area under the curve, and
90 computational efficiency. Simulation results reveal that the proposed framework significantly outperforms
91 state-of-the-art models from both quantitative and qualitative perspectives. The main contributions of this
92 work can be summarized as follows:

- 93 • We propose an automated end-to-end deep learning framework based on MobileNet CNN with KL
94 divergence loss function for Covid-19 recognition.
- 95 • We incorporate a novel preprocessing enhancement technique consisting of AMF, NLMF, and
96 CLAHE to meet the challenges arising from data deficiency and complexity.
- 97 • We analyze the performance of the utilized preprocessing enhancement scheme to demonstrate its
98 role in enhancing the discrimination capability of the proposed model.

99 The rest of this paper is organized as follows: Section (2) illustrates the phases of the proposed method.
100 Section (3) highlights the experimental results. Section (4) discusses these results. The conclusion of this
101 study is presented in the last section.

102 PROPOSED METHOD

103 In this section, we briefly describe the scenario of the methodology used to achieve the purpose of this
104 study. The proposed method is depicted in Figure 2, which generally consists of two phases: (a) image
105 pre-processing, to overcome the existing drawbacks mentioned in the previous section; (b) training and
testing dedicated to image classification.

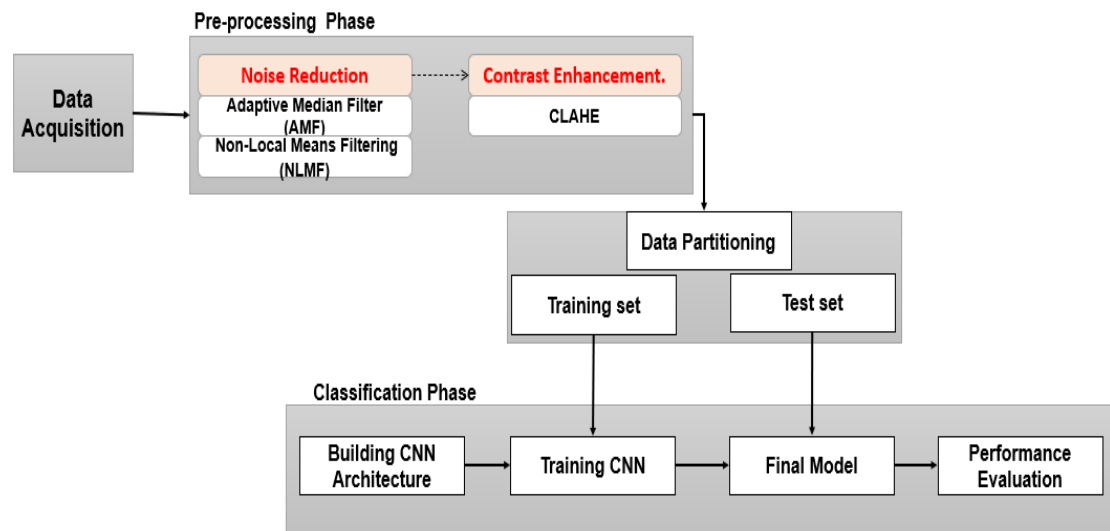

Figure 2. Study Framework.

106

107 Data Acquisition

108 In this paper, we used the COVIDx dataset used in (Wang et al., 2020) to train and evaluate the pro-
109 posed model. In brief, COVIDx dataset is an open-source dataset that can be downloaded from <https://github.com/lindawang/COVID-Net/blob/master/docs/COVIDx.md>. The instruc-
110 tions given by COVID-Net (Wang et al., 2020) were followed to set up the new dataset. Since the
111 number of X-ray images available for positive Covid-19 cases is very small, more Covid-19 X-ray im-
112 ages from <https://github.com/ml-workgroup/covid-19-image-repository> as well
113 as [https://github.com/armiro/COVID-CXNet/tree/master/chest_xray_images/
114 covid19](https://github.com/armiro/COVID-CXNet/tree/master/chest_xray_images/covid19) were also downloaded to overcome this limitation. Duplicated images were omitted from the
115 new dataset to ensure the proposed model in training is more accurate. So, the actual number of images in
116 the Covid-19 class became 2128 instead of 1770 in COVIDX (updated on 28 January 2021). We used the
117

118 same test set that was used for evaluation in (Wang et al., 2020), making a slight change by increasing the
 119 number of Covid-19 images to 100 images instead of 92. Table 1 summarizes the number of images in
 each class and the total number of images used for training and testing.

Data	Covid19	Normal	Pneumonia	Total
train	2028	7181	4981	14100
test	100	885	594	1579

Table 1. The number of images for each class.

120

121 Data Pre-processing Method

In this study, we attempt to provide an algorithm that would increase the image quality by using a hybrid technique consisting of noise reduction and contrast enhancement. Specifically, two efficient filters are used for noise reduction while CLAHE is used for contrast enhancement. The first filter is the Adaptive Median Filter (AMF) that removes impulse noise (Ning et al., 2009; Khare and Chugh, 2014). This filter is followed by the Non-Local Means Filtering (NLMF) algorithm that calculates similarity based on patches instead of pixels. Given a discrete noisy image $u = u(i)$ for a pixel i , the estimated value of $NL[u](i)$ is measured as the weighted average of all the pixels, i.e.:

$$NL[u](i) = \sum_{j \in \mathcal{N}_i} w(i, j) \cdot u(j) \quad (1)$$

122 where the weights family $w(i, j)$ depends on the similarity between the pixels i and j .

The similarity between the two pixels i and j is defined by the similarity of the intensity of gray-level vectors $u(N_i)$ and $u(N_j)$, where N_i signifies a square neighborhood of fixed size and centered at a pixel L . The similarity is measured as a function to minimize the weighted Euclidean distance, $\|u(N_i) - u(N_j)\|_{(2,a)}^2$ where $a > 0$ is the Gaussian kernel standard deviation. The pixels with a similar gray-level neighborhood to $u(N_i)$ have larger weights in the average. These weights are defined as,

$$w(i, j) = \frac{1}{Z_{(i)}} e^{-\frac{\|u(N_i) - u(N_j)\|_{(2,a)}^2}{h^2}} \quad (2)$$

123 where $Z_{(i)}$ is the normalizing constant, and the settings h works as a filtering degree.

124 Next, CLAHE is applied to the denoised images to achieve an acceptable visualization and to
 125 compensate for the effect of the filtration that may contribute some blurring to the images (Huang et al.,
 126 2016; Senthilkumar and Senthilmurugan, 2014).

127 Classification Neural Network Model

We used a deep neural network structure called a MobileNet neural network (Howard et al., 2017). Before we pass the input to the neural network, we resized all images to $224 \times 224 \times 3$. These were used as input to the network. Figure 3 depicts the model diagram of the network. The first layer is a Depthwise Conv2D layer of size $3 \times 3 \times 3$ with stride 1, followed by a Conv2D layer with 64 kernels size of $1 \times 1 \times 3$ and stride 1. After that, there is another Depthwise Conv2D layer size of $3 \times 3 \times 64$ with stride 2. Then comes a convolutional layer with 128 kernels and the size of $1 \times 1 \times 64$ with stride 1 followed by a Depthwise separable convolution layer of size $3 \times 3 \times 128$ with stride 1. Then there is another convolution layer with 128 kernels size of $1 \times 1 \times 128$ with stride 1 followed by a Depthwise separable convolution layer of size $3 \times 3 \times 128$ with stride 2. After that, another convolutional layer with 256 kernels and the size of $1 \times 1 \times 128$ with stride 1 is followed by a Depthwise Separable Convolution layer of size $3 \times 3 \times 256$ with stride 2. Then another convolutional layer has 256 kernels with the size of $1 \times 1 \times 256$ with stride 1, followed by Depthwise Separable Convolution layers of sizes of $3 \times 3 \times 256$ with stride 2. Then comes a convolutional layer with 512 kernels with the size of $1 \times 1 \times 256$ with stride 1 followed by another Depthwise separable convolution layers of sizes of $3 \times 3 \times 512$ with stride 1. This is followed by five blocks of layers, each block consisting of convolutional layers with 512 kernels and the size of $1 \times 1 \times 512$ with stride 1 followed by Depthwise separable convolution layers of sizes of $3 \times 3 \times 512$ with stride 1. After that comes another convolutional layer with 1024 kernels of size $1 \times 1 \times 512$, then Depthwise separable convolution layers of sizes of $3 \times 3 \times 1024$ with stride 1. Then again, another convolutional

layer with 1024 kernels with the size of $1 \times 1 \times 1024$ with stride 1. Then a dropout layer with the rate of 0.001 is added. The dropout layer's output goes to two fully connected layers that generate the output of size 128. One fully connected layer is used to predict the mean μ , and the other is used to predict the standard deviation σ of a Gaussian distribution. The mean μ and standard deviation σ of a Gaussian distribution are used to calculate the KL loss function. The output of the fully connected layer used to predict the mean μ goes to the last layer, a fully connected layer containing the SoftMax activation function that can be used as a classifier, as defined in equation 3, where v indicates the output vector, o indicates the Objective vector, and p_j indicates the input to the neuron j .

$$\text{SoftMax}(o, v) = - \sum_{i=1}^v o_i \log \left(\frac{e^{p_i}}{\sum_j^v e^{p_j}} \right) \quad (3)$$

The KL divergence between the μ , σ distribution and the prior are considered as a regularization which helps to overcome the over-fitting problem defined in equation 4.

$$KL = - \frac{1}{2} \sum_{i=1}^n (1 + \log(\sigma_i) - \mu_i^2 - \sigma_i) \quad (4)$$

128 where n is the output vector of the average pooling layer with the size of 1024, μ is the mean that has
 129 been predicted from one fully connected layer, and σ is the standard deviation of a Gaussian distribution
 130 predicted from one fully connected layer in the network.

131 As soon as the data is pre-processed, the network is trained with a SoftMax classifier for 200 epochs
 132 using Adam optimizer (Kingma and Ba, 2014) on a GPU. The dataset used for training is divided: 70% as
 133 a training set and 30% as a validation set. The total number of parameters is 3,488,426, where the number
 of trainable parameters is 3,466,660, and the non-trainable parameters are 21,766.

Figure 3. The architecture of the proposed neural network.

134

135 Experiments

136 All CXRs were resized to the same dimension of 224×224 in .jpg format. In the first phase, the AMF
 137 window size was taken to be 5×5 for effective filtering. The resultant image was subjected to the NLMF
 138 technique. The performance of NLMF depends on 7×7 of the search window, 5×5 of the similarity
 139 window, and the degree of filtering $h = 1$. Furthermore, we increased contrast using CLAHE with the bin
 140 of 256 and block-size of 128 in slope 3 to get the enhanced images. The proposed model (KL-MOB) was
 141 trained using the Python programming language. All experiments were conducted with a Tesla K80 GPU
 142 graphics card on Google Collaboratory with Windows 10 operating system. The original and enhanced
 143 images were used separately to train the KL-MOB, using Adam optimizer, with the initial learning rate
 144 set to 0.00001, on 200 epochs. We passed the images to KL-MOB as the input to predict the CXR image,
 145 whether Covid1-9, normal, or pneumonia. Because many functions are not built-in functions in deep
 146 learning libraries, such as the relu6 activation function with a max value of 6, we needed to build an
 147 interface for the evaluation process that contains all layers in the network as in a training network but
 148 which is not used for training. Rather, it is just used to pass on the input image to produce the output
 149 result.

150 Performance Evaluation

151 Pre-processing Performance Evaluation

152 The performance of the proposed preprocessing technique was quantified by using various evaluation
153 metrics such as Mean Average Error (MAE) and Peak Signal to Noise Ratio (PSNR). These metrics are
154 desirable since they are fast to quantify.

Definition: $x(i, j)$ denotes the samples of the original image, $y(i, j)$ denotes the samples of the output image. M and N are the number of pixels in row and column directions, respectively. MAE is calculated as in equation 5, where a large value means that the images are of poor quality.

$$MAE = |E(x) - E(y)| \quad (5)$$

The limited value $PSNR$ implies that the images are of low quality. $PSNR$ is described in terms of Mean Square Error MSE as follows:

$$PSNR = 10 \log_{10} \frac{MAX^2}{MSE} \quad (6)$$

where MAX^2 is the maximum possible pixel intensity value 255 when the pixel is represented by 8 bits.

$$MSE = \sqrt{\frac{1}{MN} \sum_{i=1}^{M-1} \sum_{j=1}^{N-1} [x(i, j) - y(i, j)]^2} \quad (7)$$

155 Neural Network Performance Evaluation

The test set described in the previous section was used to evaluate KL-MOB. The classification outcome has four cases: True Positive (TP), False Positive (FP), True Negative (TN), and False Negative (FN). The metrics used to measure the performance are Accuracy (ACC), Sensitivity (TPR), Specificity (SPC), and Precision (PPV), defined as follows:

$$Accuracy (ACC) = \frac{TP + TN}{TP + FP + TN + FN} \quad (8)$$

$$Sensitivity (TPR) = \frac{TP}{TP + FN} \quad (9)$$

$$Specificity (SPC) = \frac{TN}{FP + TN} \quad (10)$$

$$Precision (PPV) = \frac{TP}{TP + FP} \quad (11)$$

The graph plotted between True Positive Rate (TPR) and False Positive Rate (FPR) is the receiver operating characteristic (ROC) curve. FPR is calculated as follows:

$$False Positive Rate (FPR) = \frac{FP}{FP + TN} \quad (12)$$

156 RESULTS

157 In the experiments, noise reduction and contrast enhancement performance were evaluated independently
158 since they are two separate issues. The average value was computed for all images in each class. The
159 evaluation results are shown in Tables 2, and 3 for noise reduction and image enhancement, respectively.
160 Figure 4 shows noise reduction techniques that were applied to the original image and the hybrid method
161 used in this work. Though the denoising filters could present smoothing and blurring to the resulting
162 images, this can be enhanced by improving the images' edges and by highlighting the high-frequency
163 components to remove the residual noise. Figure 5 displays the original images and their enhanced
164 versions

Figure 4. The applied noise reduction techniques on the images: (a) original image, (b) image denoised by AMF, (c) image denoised by NLMF, (d) image denoised by our method.

Method	Covid19		Normal		Pneumonia	
	PSNR	MAE	PSNR	MAE	PSNR	MAE
AMF	21.91	14.46	21.19	17.88	20.43	19.47
NLMF	20.47	19.19	20.41	19.41	20.40	19.40
our method	22.04	14.38	21.21	17.59	20.45	19.32

Method	Covid19		Normal		Pneumonia	
	PSNR	MAE	PSNE	MAE	PSNR	MAE
CLAHE	17.83	27.35	17.12	25.98	21.91	16.20
our method	19.14	23.13	17.28	25.45	22.11	16.01

Table 3. The average values of PSNR (dB) and MAE for the different contrast enhancement methods.

	Enhanced image				Original image			
	ACC%	PPV%	SPC%	TPR%	ACC%	PPV%	SPC%	TPR%
Covid19	99.87	99.00	99.93	99.00	92.61	96.83	99.13	74.39
Normal	98.24	98.30	97.85	98.64	97.11	98.17	98.99	93.86
Pneumonia	97.99	97.81	98.68	97.31	91.00	81.30	86.74	98.26
Overall	98.70	98.37	98.82	98.32	93.57	92.10	94.95	88.84

Table 4. The evaluation metrics of KL-MOB on enhanced and original images.

165 In this experiment, the proposed KL-MOB model was trained on original and enhanced images to
 166 detect whether they were Covid-19, normal, or pneumonia cases. The evaluation process of the proposed
 167 KL-MOB performance was applied to each class of the dataset separately. The comparative performances
 168 of KL-MOB for the classification problem on original and enhanced images are shown in Table 4. It
 169 is noted that the proposed method has boosted the performance of KL-MOB in Covid-19 detection, as
 170 shown in the Figures 6, and 7.

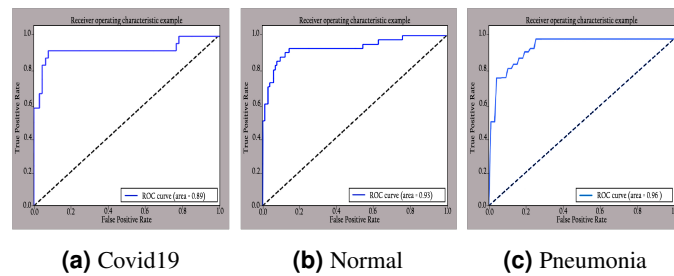

Figure 6. ROC curve of different classes on original images.

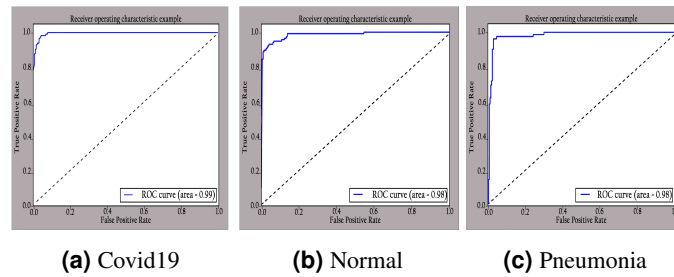

Figure 7. ROC curve of different classes on enhanced images.

171 DISCUSSION

172 In this work, a new approach based on blending noise-eliminate algorithms with contrast enhancement was
 173 presented. Adaptation of such an approach introduced a type of hybrid filtering and contrast enhancement
 174 for the data set of images used for Covid19 detection. Well-known measurable methods—Peak Signal to
 175 Noise Ratio (PSNR) and Mean Average Error (MAE)— were used as Image Quality Measurements (IQM)
 176 for assessing and comparing image quality. The results of Table 2 show that using an AMF followed
 177 by NLMF was entirely favorable for eliminating noises. Our hybrid algorithm was applied to the entire
 178 image instead of parts of the image while preserving important details. Figure 8 illustrates the difference
 179 between the original and enhanced CXRs by the method used in this work. Furthermore, we found that
 180 the damage of the lung in the enhanced image is more perspicuous than in the original image. In addition,
 CLAHE with a bin of 256 gave the best PSNR value, as shown in Table 3.

Figure 8. The images in the first and third columns show three cases of original images; the images in the second and fourth columns show three cases of enhanced images.

182 The results presented in Table 4 show that the proposed network performed well on the test set,
 183 which proves that the method used for image pre-processing boosted the performance of KL-MOB. The
 184 confusion matrix of our proposed network is depicted in Figure 9. It shows that all classes are identified
 185 with high true positives. It is to be noted that the Covid-19 cases are 99% correctly classified by the
 186 KL-MOB. There are 1% of Covid-19 cases misclassified as pneumonia (non-Covid-19), and 1.4% of
 187 the normal cases are misclassified as pneumonia. Only 0.2% of pneumonia (non-Covid-19) cases are
 188 wrongly classified as Covid-19. These results demonstrate that our proposed KL-MOB has good potential
 189 in detecting Covid-19; in particular, with limited Covid-19 cases, we show that there is no confusion
 190 between the normal and Covid-19 patient groups.

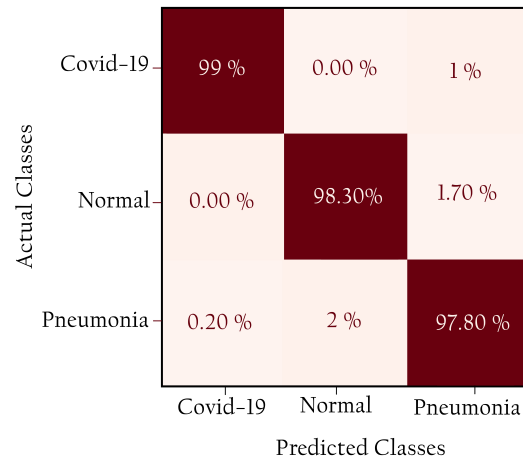

Figure 9. Confusion matrix for KL-MOB on the COVIDx test dataset.

191 In our experiment range of 100 patient samples of Covid-19, only one was misclassified with a 99.0%
 192 PPV for Covid-19, which is an appropriate value compared with 98.9%, and 96.12% for (Wang et al.,
 193 2020; Rezaul Karim et al., 2020), respectively. In addition, the results obtained from KL-MOB have
 194 been compared with previous studies that used the same or similar datasets for evaluation, as outlined in
 195 Table 5. The other studies (Farooq and Hafeez, 2020; Afshar et al., 2020; Hirano et al., 2020; Ucar and
 196 Korkmaz, 2020), not included in Table 5 for performance comparisons, utilized smaller datasets. The
 197 results showed that KL-MOB is superior to (Wang et al., 2020; Ahmed et al., 2020) across all performance
 198 metrics of accuracy, sensitivity (TPR), specificity, and PPV for overall detection.

Study	Classifier	ACC%	SPC%	TPR%	PPV%

proposed method	KL-MOB	98.7	98.82	98.32	98.37

Table 5. Comparative performance of different models.

199 The promising deep learning models used for the detection of Covid from radiography images indicate
 200 that deep learning likely still has untapped potential and can possibly play a more significant role in
 201 fighting this pandemic. There is definitely still room for improvement, through other processes such as
 202 increasing the number of images, implementing another pre-processing technique i.e., data augmentation,
 203 utilizing different noise filters, and enhancement techniques.

204 CONCLUSION

205 In this work, we proposed a novel CNN-based MobileNet structure neural network for Covid19 detection
 206 using COVIDx, the most widely used public dataset of CXR images to date. As well, the evaluation
 207 results show that our approach outperforming a recent approach with accuracy, specificity, sensitivity,
 208 and precision of 98.7%, 98.82%, 98.32%, and 98.37%, respectively. The proposed method relied on

209 image manipulation by applying a hybrid technique to enhance the visibility of CXR images. This
210 advanced pre-processing technique made the task of KL-MOB easier and better able to extract features, as
211 it helped to recognize complex patterns from medical images at a level comparable to that of experienced
212 radiologists. The KL loss function was used to boost the performance of KL-MOB which outperformed
213 recent approaches as shown in the obtained results. Considering several essential factors such as Covid-19
214 infection spreading patterns, image acquisition time, scanner availability, and costs, we hope our findings
215 will be a useful contribution to the fight against Covid-19 and towards an increasing acceptance and
216 adoption of AI-assisted applications in clinical practice. As future work, we will further enhance our
217 method's performance by including the lateral view of CXR images in our training data, as in some of the
218 cases, frontal view of CXR images does not give a clear idea in diagnosing pneumonia cases. Further,
219 since only a limited amount of CXR images for Covid-19 infection cases, the potential for issues to arise
220 is out-of-distribution is possible, therefore, more unseen data from related distributions is needed for
221 further evaluation. Finally, the enhancement of the images must be verified with a radiologist, which we
222 have not yet been able to do due to the emerging conditions.
