Abstract

Background: There is a great demand for more rapid tests for SARS-COV-2 detection to reduce waiting time, boost public health strategies for combating disease, decrease costs, and prevent overwhelming laboratory capacities. This study was conducted to assess the performance of 10 antigen-based rapid assays for the detection of SARS-CoV-2 in nasopharyngeal swab specimens.

Methods: We analyzed 231 nasopharyngeal samples collected from October 2020-December 2020, from suspected COVID-19 cases and contacts of positive cases at Biotechnology Research Center laboratories, Tripoli, Libya. The performance of 10 COVID-19 Ag rapid test devices (Fluorecare, ESPLINE, RapiGen, Abbott Panbio, Flowflex, Acon, Assut Europe, Orient Gene, CerTest, Bioperfectus, AMP) for the detection of SARS-CoV-2 antigen was compared to RT-qPCR.

Results: Among the 108 positive samples detected by RT-qPCR, the COVID-19 antigen (Ag) tests detected 83, giving a sensitivity of 76.85% (95% CI, 67.75- 84.43). 161 patients were symptomatic. The median cycle threshold was 25. The mean duration from symptom onset was 6.6 ±4.3 days. Sensitivity and specificity during the first 6 days of symptoms and in samples with high viral loads ct<25, was 96.4%. No false positives were detected by any of the Ag tests utilized in this study. False negative samples had a median Ct of 34 and average duration of onset of symptoms of 11.3 days (range=5-20).

Conclusions: Rapid antigen test diagnosis has high sensitivity and specificity in early disease when patients present less than 7 days of symptom onset. Patients are encouraged to test as soon as they get COVID-19 related symptoms within 1 week and to seek medical advice within 24 hrs. if they develop disturbed smell/taste. The use of rapid antigen tests is important for controlling COVID-19 pandemic and reducing burden on molecular diagnostic laboratories.

Keywords: Rapid antigen tests, SARS-CoV-2, COVID-19 diagnosis, Surveillance

Introduction

Nucleic acid amplification test using RT-PCR assay is currently the mainstay diagnostic test

for COVID-19 in most laboratories. However, results of RT-PCR assays can take several days

to deliver hampering the disease containment efforts. Consequently, there is an emerging

demand for more rapid and easier tests to reduce waiting time, boost public health strategies

for combating disease, decrease costs, and prevent overwhelming laboratory capacities. SARS-

CoV-2-rapid antigen tests have been largely developed and many countries have adopted them

for diagnosis in triage and hospital settings and in some countries are being used at points of

entry ("Rapid Antigen test," 2020).

The World health organization encourages laboratories to evaluate the performance of

commercial rapid antigen assays to update the current evidence and recommend specific test

kits (World Health Organization (WHO), 2020).

Libyan health authorities have approved the use of rapid antigen tests in triage, isolation centers

and hospitals ("Press conference for scientific consultancy committee for coronavirus epidemic

in Libya," 2020). This study was conducted to assess the performance of 10 antigen-based

rapid assays for the detection of SARS-CoV-2 in nasopharyngeal swab specimens from

suspected COVID-19 cases and contacts.

Methods

Antigen Test procedure

We evaluated the performance of 10 rapid antigen tests for SARS-COV-2, based on colloidal

gold chromatography immunoassay (Fluorecare SARS-CoV-2 spike protein test, Shenzhen

Microprofit Biotech Co; ESPLINE SARS-CoV-2, Fujirbio; RapiGen Covid-19 Ag Detection

Kit, Biocredit; Abbott Panbio™ COVID-19 Ag Rapid Test; Flowflex™ SARS-CoV-2 Antigen

Rapid Test, Acon; Assut Europe antigen testing COVID-19, Coronavirus ag rapid test cassette

Orient Gene, CerTest SARS-CoV-2 one step card test; Certest Biotech, Bioperfectus SARS-

CoV-2 Antigen Rapid Test Kit; bioPerfectus technologies, AMP Rapid Test SARS-CoV-2 Ag;

AMP diagnostics). All assays detect SARS-CoV-2 nucleoprotein except Fluorcare assay which

detects spike protein. Tests were performed according to the manufacturer's protocol; briefly

nasopharyngeal swabs were placed in extraction solution, swirled 10 times and squeezed

against the collection tube wall. Extracted sample was applied on a cassette and allowed to

react with a monoclonal anti- SARS-CoV-2 antibody, after a 15-30-min incubation, for the

presence or absence of bands and its intensity following antigen-antibody reaction. Positive

result was defined by clear intense band at the T (test) mark on the cassette, weak positive was

defined by faint to moderately intense band. Negative results indicate no visible band. If control

reaction failed the test was considered invalid test and repeated. The results were read by two

independent observers.

RT-PCR assay

RNA was extracted from viral transport media using magnetic bead NuActor Automatic

Extractor (Boditech Med, South Korea). All patient samples were also tested by RT-PCR

(Xpert Xpress SARS-CoV-2 GeneXpert or DAAN GENE RT-PCR COVID-19 detection kit)

within 24 hrs after collection. Both assays target Nucleocapsid (N) gene for which cycle

threshold (Ct) was considered in this study. We tested 31 nasopharyngeal swabs which was

put in the lysis buffer used for antigen testing after transferring them into viral transport media

3

for RT-PCR.

Statistical analysis

Sensitivity, specificity, positive and negative predictive values and accuracy were calculated

using MedCalc online statistical software ("MedCalc's Diagnostic test evaluation calculator,"

n.d.). Laboratory COVID-19 prevalence data were obtained from Biotechnology Research

Center case registry for the study period (unpublished).

Sensitivity was calculated as: (true positives)/ (true positives + false negatives) x 100

Specificity was calculated as: (true negatives)/ (true negatives + false positives) x 100

Positive predictive value:

Sensitivity x prevalence/sensitivity x prevalence + (1-specificity) x (1-prevalence)

Negative predictive value:

Specificity x (1-prevalence)/(1-sensitivity) x prevalence + (specificity) x (1-prevalence)

Accuracy: Sensitivity \times Prevalence + Specificity \times (1 – Prevalence)

Clinical Samples

A total of 231 patients with clinical features suggestive of COVID-19 or a history of close

contact with COVID-19 positive patient were enrolled in this study from October 10 -

December 31 2020. Few patients were asymptomatic and had no history of contact (Table 1).

Testing was performed at variable times following symptom onset,

Ethical approval for this study was granted by Biotechnology Research Center Bioethics

committee and informed consent was taken from all participants.

Results

A total of 108 nasopharyngeal samples tested positive for SARS-CoV-2 by RT-PCR

accounting for 46.75% of cases. The mean duration from symptom onset was 6.6 ± 4.3 . Among

positive samples, the COVID-19 antigen (Ag) tests detected 83 out of 108 samples, resulting

in a sensitivity of 76.85% (95% CI, 67.75- 84.43). Among negative samples, the COVID-19

Ag test detected all 123 samples as negative. No false positives were detected by any of the Ag tests utilized in this study; however, the false negative rate was 10.8% (25/231). False negative samples had a median Ct of 34 and average duration of onset of symptoms of 11.3 days (range=5-20). The prevalence of positive samples calculated from Biotechnology Research Center lab database during the study period. At 27% SARS-CoV-2 infection prevalence, estimated positive and negative predictive values were 100% and 92.1% (95% CI, 89.23% to 94.28%), respectively.

We evaluated the sensitivity of each antigen test from the first day of symptoms up to 6 days, >7, 7-9, 10-12 and >12 days (Figure 1). In this study, sensitivity and specificity during the first 6 days of symptoms and in samples with high viral loads ct<25, was 96.4%. Table 2 shows sensitivity and specificity for each individual test. The median RT-PCR cycle threshold (Ct) value of positive samples was 25. The majority of antigen test platforms had excellent performance during the first 6 days post symptom onset was between 75-100% (table 3).

Three (3/58, 5.2%) patients who were asymptomatic at the time of testing with history of close contact with a confirmed SARS-CoV-2 case tested positive by antigen test. The Cts of their RT-PCR assay were 23,24 and 25 and duration since contact were 5,6 and 10 days respectively. All other asymptomatic cases with exposure were correctly diagnosed as negative. All asymptomatic cases with no history of exposure were also tested negative by Ag test. Among symptomatic patients, the sensitivity was 77%.

We have also observed in our study that more than third of COVID-19 patients (15/41, 36.5%) who presented with loss of smell were not detected by antigen test. In this subgroup, the mean duration since symptoms onset was 12 days and the mean Ct was 34. However, those who had altered smell/taste and tested positive had a mean of 6.6 days since symptoms onset and mean Ct was 25. In few patients, loss of smell/taste was the only symptom (3/41, 7.3%).

Although the recommended time for interpretation ranges between 10-30 minutes, in all

samples with CT< 25 the test Line was clearly visible within 2 minutes of application which

gave a rough estimation of viral load. When interpretating results after or before the time set

by the manufacturer, it was observed that positive test line either faded or became unreadable

in most cassette assays. Also, the result interpretation before the end of recommended time was

unreliable in cases with low viral load (cycle threshold above 25).

The cycle threshold for nasopharyngeal swab positive samples used for antigen testing and then

transferred to VTM for RT-PCR was increased 3-6 cycles in comparison with other direct

swabs.

Discussion

Rapid antigen testing is cost-effective, easy to use and can be manufactured in large quantities.

The timeliness of results they provided will reduce the load on the diagnostic laboratories. The

FDA has authorized 14 SARS-CoV-2 antigen diagnostic tests for emergency use as of 19th

March, 2021 ("In Vitro Diagnostics EUAs | FDA," n.d.). Most of these tests are lateral flow

assays that can be visually read. We aimed to study rapid antigen tests from different

manufacturers to evaluate their performance using time since the onset of symptoms as criteria

for testing. This study was also part of pre-implementation evaluation to confirm performance

of the tests by RT-PCR.

Our study showed that most Ag-RDTs examined were reliable to diagnose SARS-CoV-2

infection. They demonstrated excellent performance in samples with high viral load ct≤25

which are usually samples taken within the first six days after the onset of symptoms. Certest

Biotech, Panbio, Rapigen, Acon Ag RDT demonstrated similar results to studies reported by

other authors during the first week (Aoki et al., 2021; Linares et al., 2020; Pérez-García et al.,

2021). The World health organization recommended the use of SARS-CoV-2 antigen rapid

tests (Ag-RDTs) that meet a minimum sensitivity of $\geq 80\%$ and $\geq 97\%$ specificity compared to

a nucleic acid amplification test reference assay (World Health Organization (WHO), 2020).

All tests showed a specificity of 100 % and sensitivity over 90 % for high viral load samples,

with excellent levels of agreement with PCR in 8 out of 10 tests. Two rapid ag tests showed

sensitivity below the WHO recommended value.

It is worth emphasizing that interpretation time should not subceed nor exceed the

manufacturer's recommended time to avoid false interpretation of the test result. The intensity

of test line color is proportionally correlated with viral load. The test line in low viral load

samples may appear weak or faint which may not be clearly visible to the reader. Therefore,

an additional independent reader is recommended when low viral loads are expected to reduce

subjectivity and confirm diagnosis but for most cases one reader is sufficient for interpreting

the results. We also don't recommend placing the same nasopharyngeal swab used for antigen

test in viral transport media for RT-PCR analysis as the viral material will be diluted and may

give false negative results.

Since SARS-CoV-2 cases have been increasing with emergence of new variants (Lauring and

Hodcroft, 2021), and numerous antigen tests were manufactured, it is important to evaluate

them before implementation. Although there is more risk of developing false negative results

after 7 days of symptom onset, this is largely counter-balanced by the rapidity of the test

especially when used in targeted population. Our study shows that all COVID-19 Ag tests had

a good specificity for SARS-CoV-2 detection in nasopharyngeal swab samples but had a good

sensitivity only for cases within 7 days of developing symptoms (higher viral loads).

We proposed a strategy for use of rapid antigen tests in symptomatic patients according to our

results and experience as shown in the flowcharts (Fig 2a and b). Although the procedure is

relatively easy to perform, testing with Ag-RDTs should be conducted by trained operators

following manufacturer's instructions. Interpretation of the results of rapid antigen tests should consider prevalence of the disease in the community because positive and negative predictive value of any diagnostic test is affected by disease prevalence in the population tested. (World Health Organization (WHO), 2020).

In our medical departments, triage and isolation centers, we have trained medical staff on how to use the antigen test properly, developed criteria for testing (figure 2) and audited the procedure. It is important to note that the use of rapid antigen test requires careful respiratory sample management, waste disposal and biosafety considerations.

The incubation period of SARS-CoV-2 infection was estimated between 3 and 6 days with a median incubation of 4 days (Guan et al, 2020; Meo et al, 2020). Many patients only present to the hospital 6-10 days following symptom onset (Chan et al, 2020). Therefore, missing the opportunity for rapid detection using antigen tests. We consequently emphasize the importance of encouraging patients to seek medical advice and immediate testing as soon as they develop any COVID-19 related symptoms. In particular when patients lose sense of smell, they should be tested immediately, preferably within 24 hrs. because this symptom usually occurs after onset of other COVID-19 symptoms (Chetrit et al., 2020; Salmon Ceron et al., 2020). We also observed in our study that most patients present with loss of smell few days after symptoms onset and in some patients, it was the sole symptom (12 pts with loss of smell came late). We believe that Ag testing will encourage patients to come earlier for testing because of reduction in waiting time.

Viral culture studies in cell lines showed that samples with Ct value ≥ 34 , ≥ 24 or ≥ 38 and more than 8 days of symptoms onset had no growth and thus might indicate the person is less infectious. (Bullard et al., 2020; La Scola et al., 2020; Wölfel et al., 2020). Thus, there is no agreement about the cut-off Ct value. A positive PCR results reflects only the detection of viral

RNA and not necessarily indicate the presence of viable virus Therefore, false negative results

could potentially be non-infectious, increasing the safety margin in the utility of rapid antigen

test in cases more than 7 days after start of symptoms and asymptomatic patients.

This study has some limitations. First, the sample size was small for each individual antigen

test kit. Second, because the data was collected prospectively based on presence of symptoms

or history of contact with infected patient, it was difficult to select patients with different Ct

values in enough size. However, if we assumed that the performance of all antigen kits was

similar, the data would reliable enough to give credible results.

Antigen testing performance is mostly affected by symptoms duration, viral load,

manufacturing company, operator experience and qualification. In addition, new SARS-COV-

2 variants may alter the performance especially with spike proteins targeted antigen tests (Li et

al., 2020; Mahase, 2020).

In conclusion, rapid antigen tests have high sensitivity and specificity in early disease when

patients present before 7 days of symptom onset. Patients are encouraged to test as soon as they

get COVID-19 related symptoms within 1 week and to seek medical advice within 24 hrs. if

they develop disturbed smell/taste. The use of rapid antigen tests is important for controlling

COVID-19 pandemic and reducing burden on molecular diagnostic laboratories.
