20 **Abstract**

21 **Background:** Therapeutically immunosuppressed transplant recipients exhibit attenuated
22 responses to COVID-19 vaccines. To better understand the immune alterations that determined

23 poor vaccine response, we correlated quantities of circulating T and B cell subsets at baseline
24 with longitudinal serologic responses to SARS-CoV-2 mRNA vaccination in heart and lung
25 transplant recipients.

26 **Methods:** Samples at baseline and at approximately 8 and 30 days after each vaccine dose for 22
27 heart and lung transplant recipients with no history of COVID-19, four heart and lung transplant
28 recipients with prior COVID-19 infection, and 12 healthy controls undergoing vaccination were
29 analyzed. Anti-spike protein receptor binding domain (RBD) IgG and pseudovirus neutralization
30 activity were measured. Proportions of B and T cell subsets at baseline were comprehensively
31 quantitated.

32 **Results:** At 8-30 days post vaccination, healthy controls displayed robust anti-RBD IgG
33 responses, whereas heart and lung transplant recipients showed minimally increased responses.
34 A parallel absence of activity was observed in pseudovirus neutralization. In contrast, three of
35 four (75%) transplant recipients with prior COVID-19 infection displayed robust responses at
36 levels comparable to controls. Baseline levels of activated PD-1⁺ HLA-DR⁺ CXCR5⁻ CD4⁺ T
37 cells (also known as T peripheral helper [T_{PH}] cells) and CD4⁺ T cells strongly predicted the
38 ability to mount a response.

39 **Conclusions:** Immunosuppressed patients have defective vaccine responses but can be induced
40 to generate neutralizing antibodies after SARS-CoV-2 infection. Strong correlations of vaccine
41 responsiveness with baseline T_{PH} and CD4⁺ T cell numbers highlights a role for T helper activity
42 in B cell differentiation into antibody secreting cells during vaccine response.

43 **Introduction**

44 For immunocompetent individuals, SARS-CoV-2 vaccination is a highly effective preventative
45 approach for protection from COVID-19 (1–3). However, because Phase 3 trials excluded
46 immunosuppressed individuals, the approach to and determinants of induction of protective
47 immunity against SARS-CoV-2 among transplant recipients and other severely
48 immunosuppressed individuals is less clear.

49 Heart and lung transplant recipients require a higher degree of immunosuppression to prevent
50 graft rejection than other solid organ transplant recipients. Their regimens typically include a
51 calcineurin inhibitor (tacrolimus more often than cyclosporine), a DNA synthesis inhibitor
52 (mycophenolate more often than azathioprine) and/or a mammalian target of rapamycin (mTOR)
53 inhibitor (sirolimus), and low-dose glucocorticoids. Whereas both DNA synthesis inhibitors and
54 calcineurin inhibitors block T cell expansion, tacrolimus may particularly impact follicular
55 helper T cells (4), which are critical for the affinity maturation and isotype switching of an
56 effective antibody response. Loss of mTOR activity not only blunts T and B cell proliferation,
57 but also impairs the development of CD8⁺ T cell memory (5), skews helper T cell differentiation
58 toward regulatory T cells (6, 7), and disrupts B cell progression through germinal center
59 reactions, including class switching and somatic hypermutation (8–10). Furthermore,
60 glucocorticoids interfere with activities of virtually all immune cells.

61 Previous to COVID-19, several reports demonstrated attenuated or delayed serologic responses
62 to various vaccines among severely immunosuppressed hosts (11–15). Vaccine efficacy in this
63 patient population may depend in part on the nature of the vaccine and is sometimes improved by
64 booster vaccination (16). Published data on antibody responses to SARS-CoV-2 mRNA

65 vaccination in transplant recipients indicate major impairments in vaccine-induced humoral and
66 cellular immunity (16–25). Whether transplant recipients are uniquely vulnerable to more
67 transmissible viral strains with spike protein variants, which are rising in prevalence globally,
68 remains unclear. Hence, there is an urgency to determine why transplant recipients do not
69 respond to standard SARS-CoV-2 mRNA vaccinations and to identify solutions to protect this
70 vulnerable patient population.

71 Here, we quantitatively assessed the antibody response to SARS-CoV-2 vaccination among heart
72 and lung transplant recipients, including neutralization activity to emerging variants of concern,
73 extending recent findings from other groups (17, 22–25). Further, to identify cellular correlates
74 of adaptive immune determinants of vaccine responsiveness, we quantified subsets of CD4⁺ T
75 helper cells, CD8⁺ T cells, and B cells at baseline and correlated these with levels of serum IgG.

76 **Results**

77 **Serum IgG responses among vaccinated heart and lung transplant recipients were**

78 **markedly diminished compared to those of healthy controls.** Among vaccinated heart and

79 lung transplant recipients with no evidence of prior or intercurrent (between vaccine doses)

80 COVID-19 infection (N=16 heart and N=6 lung transplant recipients), levels of IgG recognizing

81 the SARS-CoV-2 RBD were markedly lower than those of healthy controls (Fig. 1). At 8 and 30

82 days after the second vaccine dose, IgG anti-RBD levels were 22-fold lower ($p = 2.9 \times 10^{-7}$;

83 Wilcoxon rank-sum test) and 20-fold lower ($p = 6.7 \times 10^{-4}$; Wilcoxon rank-sum test),

84 respectively, among transplant recipients compared to those of healthy controls.

85 **Neutralization activity of plasma from vaccinated heart and lung transplant recipients**

86 **were markedly diminished compared to that of healthy controls.** Neutralization activity to

87 SARS-CoV-2 pseudovirus among vaccinated heart and lung transplant recipients largely

88 paralleled IgG levels. At 8 days after the second vaccine dose, mean neutralizing antibody

89 activity of transplant recipients was 12.2-fold less than that of healthy controls ($p = 2.9 \times 10^{-7}$,

90 Wilcoxon rank-sum test, Fig. 2A), and at 30 days after the second vaccine dose, neutralizing

91 antibody activity of transplant recipients was 12.0-fold less than that of healthy controls

92 (Wilcoxon rank-sum test, $p = 0.001$, Fig. 2B).

93 Similar to previously published results (26–31), among healthy controls, neutralizing activity to

94 variant pseudoviruses containing the E484K/N501Y/D614G mutations present in the beta

95 (B.1.351) and gamma (P.1) variants (originally identified in South Africa and Brazil,

96 respectively) were reduced (Fig. S1C). Among control patients at later time points (1d pre dose 2

97 through 68d post dose 2), neutralization against E484K/N501Y/D614G pseudovirus was 22%

98 lower than against D614G pseudovirus ($p = 6.6 \times 10^{-6}$, paired Wilcoxon test) and 24% lower than
99 against N501Y/D614G pseudovirus ($p = 3.8 \times 10^{-5}$, paired Wilcoxon test) (Fig. S1C),
100 representative of the alpha (B.1.1.7) variant originally identified in the United Kingdom; the
101 difference in neutralization between D614G and N501Y/D614G pseudoviruses was not
102 significant. Among both transplant recipients and healthy controls, neutralizing antibody titers
103 correlated strongly with levels of anti-RBD IgG, although this correlation decreased with
104 additional variant mutations in the RBD (Fig. S2).

105 **Time course of response.** The differences in responses between the transplant recipients and the
106 healthy controls were evident as early as 20 days after the first vaccine dose (1 day prior to the
107 second vaccine dose), when all but two healthy controls yet none of the transplant recipients
108 displayed increases in IgG above background (Figs. 3, S3, and S4). Following the second dose of
109 vaccine, IgG levels and neutralization activity progressively increased in two COVID-19-
110 uninfected transplant recipients and all of the controls (Figs. 3 and S4). Increases in
111 neutralization activity correlated highly with the increases in IgG levels (for D614G pseudovirus
112 and IgG levels, $R=0.88$, Fig. S2A). The increases in these two transplant recipients were delayed
113 compared to the controls; whether they will continue to increase at later times will be determined
114 with additional follow-up. Consistent with prior publications in which lower immunosuppression
115 is associated with improved serologic responses (17, 22–24), these two transplant recipients were
116 on levels of immunosuppression at the lower end of our cohort; one was not on a DNA synthesis
117 inhibitor, and both were on only 5 mg daily of prednisone.

118 **Prior or intercurrent infection with COVID-19 is associated with strong serological**
119 **responses and neutralizing activity.** Three transplant recipients had COVID-19 prior to
120 vaccination, and one had COVID-19 between the first and second vaccine dose. Three of these

121 four transplant recipients displayed IgG levels and neutralization activity were comparable to
122 those of healthy controls (Fig. 3B, 3D). For the three of these individuals who displayed elevated
123 IgG levels and neutralization activity, vaccination *per se* was associated with a boost in IgG
124 levels, and for one, a boost in neutralization activity; for the other two who responded, it was not
125 possible to determine whether neutralization activity was boosted, as it was >95% at baseline
126 (Fig. 3D). The proportion of subjects who responded to vaccination was significantly different
127 among transplant patients with prior COVID-19 ($p = 0.018$, Fisher's exact test). Proximity to
128 transplantation and the higher doses of immunosuppressive medications generally administered
129 around transplantation may have contributed to the absence of response in the COVID-19-
130 infected non-responder, as this individual developed infection <1 year after transplantation,
131 whereas the other three COVID-19-infected transplant recipients developed infection 2-5 years
132 (N=2) and >15 years (N=1) after transplantation. No differences in immunosuppressive regimens
133 at the time of vaccination or the severity of COVID-19 infection between the one COVID-19-
134 infected non-responder and the three COVID-19-infected responders were identified. Nor were
135 any differences in immunosuppressive regimens identified between the COVID-19-infected and
136 uninfected transplant recipients.

137 **Peripheral blood immune cell populations at early time points and cellular predictors of**
138 **antibody response.** To identify differences that may underlie the differential response to
139 vaccination, we performed high-dimensional flow cytometry on baseline samples and quantified
140 peripheral blood immune cell subsets at early time points. We found significant differences in
141 peripheral blood immune cells including CD3⁺ lymphocytes ($p = 0.04$, wilcoxon test), CD4⁺ T
142 lymphocytes ($p = 0.002$), T peripheral helper (T_{PH}) cells, Tregs ($p = 0.02$) and DR⁺ T cells ($p =$
143 0.0059). The relative proportion of T_{PH}/CD4⁺ ($p = 0.0093$), DR⁺/Tregs ($p = 0.00031$), and

144 DR⁺/CD4⁺ ($p = 0.04$) were also decreased among transplant patients as compared to controls
145 (Fig. 4A and S5A). In contrast, we did not observe significant differences in CD8⁺ T cells and
146 CD19⁺ B cell populations. To identify potential cellular predictors of the antibody response to
147 vaccination, we computed correlation statistics between baseline flow cytometry and antibody
148 response at 8 days post second dose (Fig. S5B). Most strongly correlated with antibody response
149 was the absolute number of T peripheral helper (T_{PH}) cells (Pearson correlation coefficient, $r =$
150 0.72 , $p = 0.0036$), and this relationship held for the proportion of T_{PH} cells among total CD4⁺
151 cells ($r = 0.62$, $p = 0.02$). T_{PH} cells are PD-1⁺ CXCR5⁻ HLA-DR⁺ CD4⁺ T cells and represent a
152 subset of CD4⁺ T cells that have been shown to drive B cell differentiation into antibody
153 secreting cells (32). A substantial yet weaker relationship was present between day 8 IgG levels
154 and HLA DR⁺ CD4⁺ T cells (Fig. 4B).

155 We observed no significant correlations between serologic responses and the baseline
156 proportions of total effector-memory CD4⁺ T cells, regulatory T cells, HLA-DR⁺ (activated)
157 regulatory T cells, naïve CD4⁺ T cells, or circulating T follicular helper T cells among total
158 CD4⁺ T cells, effector-memory CD8⁺ T cells, CD8⁺ cytotoxic T cells, or CD8⁺ naïve T cells
159 among total CD8⁺ T cells, naïve, unswitched memory, switched memory, or double-negative
160 (IgD⁻CD27⁻) B cells among total CD19⁺ B cells.

161 **Discussion**

162 In this study, we provide the first in-depth longitudinal comparison of immune responses to
163 SARS-CoV-2 vaccination in heart and lung transplant recipients to responses to vaccination of
164 healthy controls and of heart and lung transplant recipients with prior COVID-19 infection. In
165 addition, we provide the first correlation of these responses to quantitative analyses of baseline T
166 and B cell subsets. Consistent with findings of other investigators (16–25), we show that
167 COVID-19-naïve heart and lung transplant recipients have a profound reduction in neutralizing
168 antibodies against SARS-CoV-2 spike protein and receptor binding domain (RBD)-specific
169 immunoglobulin levels after both prime and boost vaccine doses. However, transplant recipients
170 who had COVID-19 infection prior to vaccination displayed neutralizing antibodies to SARS-
171 CoV-2 at baseline that increased following vaccination. Taken together, the disparate humoral
172 immune response to SARS-CoV-2 vaccine as compared to natural infection in heart and lung
173 transplant patients is suggestive of a failure of vaccines to induce immunologic priming in highly
174 immunosuppressed patients, and points to the need for alternate immunization regimens for these
175 populations.

176 The vast majority of participants received the two-dose BNT162b2 (Pfizer-BioNTech) mRNA
177 vaccine (88%), with only two heart and lung transplant recipients (7.7%) receiving the two-dose
178 mRNA-1273 (Moderna) vaccine and only one (3.8%) receiving the single-dose Ad26.COV2.S
179 (Janssen) adenovirus-based vaccine; as a result, we were unable to assess vaccine-related
180 outcomes and our outcomes in aggregate are largely reflective of responses to the Pfizer vaccine.
181 Our data are consistent with recent studies showing response rates of 0–49% in heart and lung
182 transplant recipients receiving the BNT162b2 mRNA vaccine (22, 24, 33, 34). These studies

183 provided evidence of lower anti-spike IgG levels in transplant recipients; we show that this is
184 corroborated by lower neutralizing antibody titers as well. These studies also showed an
185 association between poor response and the use of various immunosuppressive regimens,
186 particularly those including DNA synthesis and calcineurin inhibitors. Compared with our
187 findings, the higher response rates (up to 49%) observed in heart and lung transplant recipients in
188 three of these studies (22, 24, 33) may reflect lower proportions of patients on combined
189 calcineurin and DNA synthesis inhibition as well as maintenance steroids, whereas the vast
190 majority of transplant recipients described in Havlin et al. (34) and in our cohort, who had a
191 uniform lack of response to vaccine, are maintained on three-drug therapy.

192 The presence of robust neutralizing antibody titers in 3 of the 4 transplant recipients with prior
193 COVID-19 infection in our study suggests that heavily immunosuppressed patients can
194 nevertheless mount an effective humoral response to natural infection. This is in line with Havlin
195 et al., who found that 85% of lung transplant recipients with SARS-CoV-2 infection developed
196 spike-directed antibodies (34). The higher proportion of T_{PH} cells in transplant patients who had
197 prior COVID-19 infection may suggest an expansion in this population due to recent infection,
198 which may in turn facilitate the boost in antibody responses seen in these individuals. A corollary
199 to this is that the uniformly low numbers and proportion of T_{PH} cells in uninfected transplant
200 patients may underlie the inability of these individuals to mount spike-specific IgG responses.
201 Our data indicate that mRNA vaccination may be sufficient to boost existing responses, as anti-
202 spike antibody levels rose post-vaccination in patients with prior COVID-19 infection with
203 similar kinetics to that of healthy controls; however, mRNA vaccination is a far weaker driver of
204 immunologic priming of immune responses than natural infection.

205 The generation of long-lasting humoral immunity depends on a coordinated T and B cell
206 response to antigen. Calcineurin inhibitors have been shown to impact antibody responses by
207 inhibiting T follicular helper (T_{FH}) cell differentiation, as well as naive B cell proliferation and
208 plasmablast differentiation (4, 35). In our data, the substantial deficits in total and activated
209 $CD4^+$ in transplant patients at baseline suggests that a failure to mount appropriate T cell help
210 for B cell differentiation results in impaired class switching and memory B cell development. A
211 limitation of our analysis is that pre-vaccine measurements were available only for 3 transplant
212 patients and our “baseline” populations among transplant patients were mixtures of pre-vaccine
213 and 9 days post the first vaccine dose timepoints; however, in the three subjects in whom both
214 pre-vaccine and 9 days post the first vaccine dose timepoints were measured, the responses at the
215 two timepoints were strongly correlated ($r = 0.97$, >0.99 , and >0.99 , Fig. S7A), and no trends
216 were observed that would suggest that the observed differences in $CD4^+$ populations between
217 transplant and control were artifactual (Fig. S7B).

218 It remains unclear why natural infection is able to overcome the reduction in baseline $CD4^+$ T
219 cells in many transplant patients (3 of 4 in our study); moreover, in our study, two uninfected
220 transplant patients demonstrated an antibody response, albeit delayed (Fig. 3A and 3C). Delayed
221 responses to SARS-CoV-2 vaccination have also been reported in kidney transplant and chronic
222 dialysis patients (20, 36). The association between IgG responses and T_{PH} cells may offer a clue,
223 as these cells have been implicated in extrafollicular B cell differentiation and maintenance (37)
224 and COVID-19 infection induces expansion of T_{PH} cells (38) and increases in non-germinal
225 center B cell responses (39).

226 Based on data in humans and monkeys, anti-spike protein IgG and anti-RBD IgG are strong
227 immune correlates of protection to COVID-19 infection (40–42). The weakness of this response

228 in COVID-19-uninfected vaccinated heart and lung transplant recipients, demonstrated herein
229 and in other studies, raises major concerns that despite vaccination, this population of patients is
230 poorly protected from infection by standard vaccination strategies.

231

232 **Methods**

233 **Study participants and clinical and demographic data.** Eligible participants were heart and
234 lung transplant recipients followed clinically at our institution and healthy volunteers of similar
235 age and sex distribution. Healthy volunteers were solicited via a publicly accessible institutional
236 website (<https://rally.partners.org/>) and local newsletters. Candidates for healthy controls were
237 considered eligible if they were 30-80 years old (the same age range as enrolled transplant
238 recipients), were not receiving immunosuppressive medications, and to enable rapid processing
239 of obtained specimens, were living in eastern Massachusetts. All participants were enrolled prior
240 to or up to two weeks after SARS-CoV-2 vaccination. Demographic and clinical data and
241 vaccine type were collected from the electronic medical record and/or study participants.
242 Evidence for prior COVID-19 infection was obtained from the electronic medical record.

243 **Demographics and clinical characterization of participants.** Eighteen heart and eight lung
244 transplant recipients and 12 healthy volunteers receiving SARS-CoV-2 vaccination were
245 enrolled. The age and sex distribution of the transplant and control groups were similar (Table
246 1). About one half of the heart and lung transplant recipients were 1 to 5 years after
247 transplantation, about 15% of each group were less than one year after transplantation, and one-
248 third of heart and one-quarter of lung transplant recipients were 10 or more years after
249 transplantation (Table 1). For the two-dose vaccines (BNT162b2 and mRNA-1273), the time
250 between vaccine doses reflected each vaccine's prescribed dosing schedule, with the exception
251 of one outlier, whose second dose was delayed due to intercurrent COVID-19 infection (Fig. S6).
252 The vast majority of both heart and lung transplant recipient participants were maintained on a
253 DNA synthesis inhibitor, a calcineurin inhibitor, and prednisone; about a quarter of both heart

254 and lung transplant recipients were also maintained on an mTOR inhibitor (Table 1). Lung
255 transplant recipients were generally maintained on higher doses of prednisone than heart
256 transplant recipients; whereas 75% (6/8) of lung transplant recipients were taking ≥ 10 mg of
257 prednisone daily, only 6% (1/18) of heart transplant recipients were taking ≥ 10 mg daily. No
258 other substantial medication differences between heart transplant and lung transplant participants
259 were observed.

260 **Sample collection.** Serial blood samples were collected prior to vaccination (N=13),
261 approximately 1 week after the first dose of vaccine (N=18, median 9 days, interquartile range
262 [IQR, 25%-75%] 7-10 days), just prior to the second dose of vaccine (N=30, median 21 days,
263 IQR 19-21 days after first dose), and at approximately 1 week (N=32, median 8 days, IQR 7-10
264 days), 4 weeks (N=16, median 30 days, IQR 26-34 days), and 8-10 weeks (N=18, median 60
265 days, IQR 60-69 days) after the second dose of vaccine. Baseline blood samples were defined as
266 a sample collected prior to vaccination (N=12, including 4 transplant recipients and 8 healthy
267 controls) or a blood sample collected approximately 1 week after the first dose of vaccine (N=9,
268 all transplant recipients). Blood collection was either in the institutional Translational and
269 Clinical Research Center or the participant's home by Partners HealthCare at Home. All samples
270 were processed within 4 hours of phlebotomy. Blood samples were centrifuged, and plasma,
271 serum, and PBMCs were isolated and cryopreserved at -180°C . PBMC isolation was performed
272 using BD cell preparation tubes with sodium heparin. Tubes were centrifuged at $1800 \times g$ for 25
273 minutes. PBMC were washed in HEPES-buffered Hanks saline solution, resuspended in FBS
274 with 10% DMSO, and stored in liquid nitrogen.

275 **ELISA and neutralizing antibody assays.** Purified SARS-CoV-2 D614G spike protein receptor
276 binding domain (RBD) and whole spike protein were generously provided by Aaron Schmidt.

277 RBD enzyme linked immunosorbent assays (ELISAs) to IgG in participant serum were
278 performed as previously described (43). Measurements were performed in triplicate and the
279 mean of the three replicates was used. Absolute concentrations were determined based on a
280 standard curve fitted in R using the `drm` package. Inferred values above 1.25mg/uL, twice the
281 value of the most concentrated standard, were replaced with 1.25 mg/uL, a procedure which
282 affected only two samples (9d post dose 1 and 1d pre dose 2) from one individual, a heart
283 transplant recipient with prior COVID-19. Neutralizing activity of plasma against SARS-CoV-2
284 D614G, N501Y/D614G (representative of RBD of variant B.1.1.7), and E484K/N501Y/D614G
285 (representative of RBD of variants B.1.351 and P.1) spike protein pseudoviruses were assayed as
286 previously described (44). pCMV-SARS2SΔC D614G-gp41 was generated by PCR mutagenesis
287 from pCMV-SARS2SΔC-gp41 and Gibson assembly. pCMV-SARS2SΔC N501Y/D614G-gp41
288 and pCMV-SARS2SΔC E484K/N501Y/D614G-gp41 were obtained by Gibson assembly of the
289 respective gBlocks (IDT) in pCMV-SARS2SΔC D614G-gp41.

290 **Flow cytometry.** To comprehensively quantitate proportions of B and T cell subsets at baseline,
291 PBMCs were studied using multicolor flow cytometry. Preserved PBMCs were thawed and
292 washed in complete DMEM. Prior to antibody staining, Fc receptors were blocked using Human
293 TruStain FcX (BioLegend, 422302) at a concentration of 1:20 on ice for 15 minutes. Cells were
294 stained sequentially, first for 20 minutes at 37°C, then washed and stained with a second cocktail
295 of antibodies for 30 minutes at 4°C, as previously optimized for each clone. The following
296 antibody panel was used to quantitate B and T cell subsets: anti-human HLA-DR-BUV395 (BD
297 Biosciences, Clone Tu39, 1:400), anti-human CD45RA-BUV563 (BD Biosciences, Clone
298 HI100, 1:600), anti-human CD38-BUV661 (BD Biosciences, Clone HIT2, 1:400), anti-human
299 CCR7-BUV737 (BD Biosciences, Clone 3D12, 1:200), anti-human CD4-BUV805 (BD

300 Biosciences, Clone SK3, 1:100), anti-human CD20-BUV805 (BD Biosciences, Clone 2H7,
301 1:100), anti-human CD25-BV421 (BioLegend, Clone BC96, 1:25), anti-human CD28-BV480
302 (BD Biosciences, Clone CD28.2, 1:100), anti-human CD21-BV480 (BD Biosciences, Clone B-
303 ly4, 1:100), anti-human CD11c-BV605 (BD Biosciences, Clone B-ly6, 1:100), anti-human CD10
304 (BD Biosciences, Clone HI10 α , 1:25), anti-human PD1-BV711 (BD Biosciences, Clone EH12.1,
305 1:100), anti-human CD86-BV750 (BD Biosciences, Clone FUN-1, 1:100), anti-human CD8-
306 BV785 (BioLegend, Clone SK1, 1:400), anti-human IgD-BV785 (BioLegend, Clone 1A6-2,
307 1:100), anti-human CXCR5-A488 (BD Biosciences, Clone RF8B2, 1:100), anti-human CD127-
308 BB700 (BD Biosciences, Clone HIL-7R-M21, 1:50), anti-human CX3CR1-PE (BioLegend,
309 Clone K0124E1, 1:25), anti-human CD27-PE-Dazzle (BioLegend, Clone M-T271, 1:100), anti-
310 human CXCR3-PE-Cy7 (BioLegend, Clone G025H7, 1:50), anti-human CCR6-APC
311 (BioLegend, Clone G034E3, 1:25), anti-human CD19-APC-R700 (BD Biosciences, Clone
312 SJ25C1, 1:25), and anti-human CD3-APC-Vio770 (Milltenyi, Clone BW264/56, 1:200).

313 After staining, cells were washed with 1% BSA in PBS, centrifuged and resuspended in 1% BSA
314 in PBS. Just prior to flow cytometry, dead cells were identified with SYTOX AADvanced Dead
315 Cell Stain (Thermo Fisher Scientific, S10274, 1:1000). Flow cytometry was performed on a BD
316 FACS Symphony cytometer (BD Biosciences, San Jose, CA), and rainbow tracking beads were
317 used to ensure consistent signals between flow cytometry batches. FCS files were analyzed using
318 FlowJo software (version 10.7.2). The surface markers used to define each cell type are provided
319 in Table 2.

320 A single aliquot of PBMC was thawed and used for flow cytometry. Each aliquot corresponds to
321 cells harvested from a single 8 mL CPT; however, absolute counts may reflect additional noise

322 incorporated during a single cycle of freezing and thawing. We therefore also report relative
323 counts as a proportion of CD4+, CD8+ and CD19+ cells.

324 **Statistics.** Raw data were analyzed with R (45). Pairwise comparisons were performed using a
325 Wilcoxon test. Correlation coefficients and associated p-values were calculated using Pearson's
326 product-moment correlation coefficient. The proportion of subjects who responded to
327 vaccination was calculated by Fisher's exact test. Response to vaccination for each subject was
328 determined by a consistent rise in IgG ELISA over time. Data were displayed using ggplot (46).

329 **Study approval:** All study procedures involving human subjects were approved by the Mass
330 General Brigham Human Research Committee, the governing institutional review board at
331 Massachusetts General Hospital. Informed consent was received from participants prior to
332 inclusion in the study, either in writing or by institutional review board-established verbal
333 consent procedures employed during the COVID-19 pandemic. Participants were identified by
334 numbers.

335 **Author contributions:**

336 J.E.L., designed research studies, recruited and consented patients, scheduled patients, conducted
337 experiments, acquired data, analyzed data, wrote manuscript.

338 A.L., designed research studies, analyzed data, wrote manuscript.

339 M.G., conducted experiments, acquired data, edited manuscript.

340 C.A.P., designed research studies, conducted experiments, acquired data, edited manuscript.

341 Z.W., recruited and consented patients, scheduled patients, acquired data, edited manuscript.

342 K.B., recruited and consented patients, scheduled patients, edited manuscript.

343 P.A., recruited and consented patients, scheduled patients, edited manuscript.

344 H.L., conducted experiments, acquired data.

345 G.D.L., recruited patients, edited manuscript.

346 N.B., conducted experiments, acquired data.

347 T.L., recruited and consented patients, scheduled patients.

348 N.H., designed research studies.

349 S.S.P., designed research studies, analyzed data, edited manuscript.

350 M.B.G., designed research studies, recruited and consented patients, scheduled patients, analyzed
351 data, wrote manuscript, raised funds to support studies.

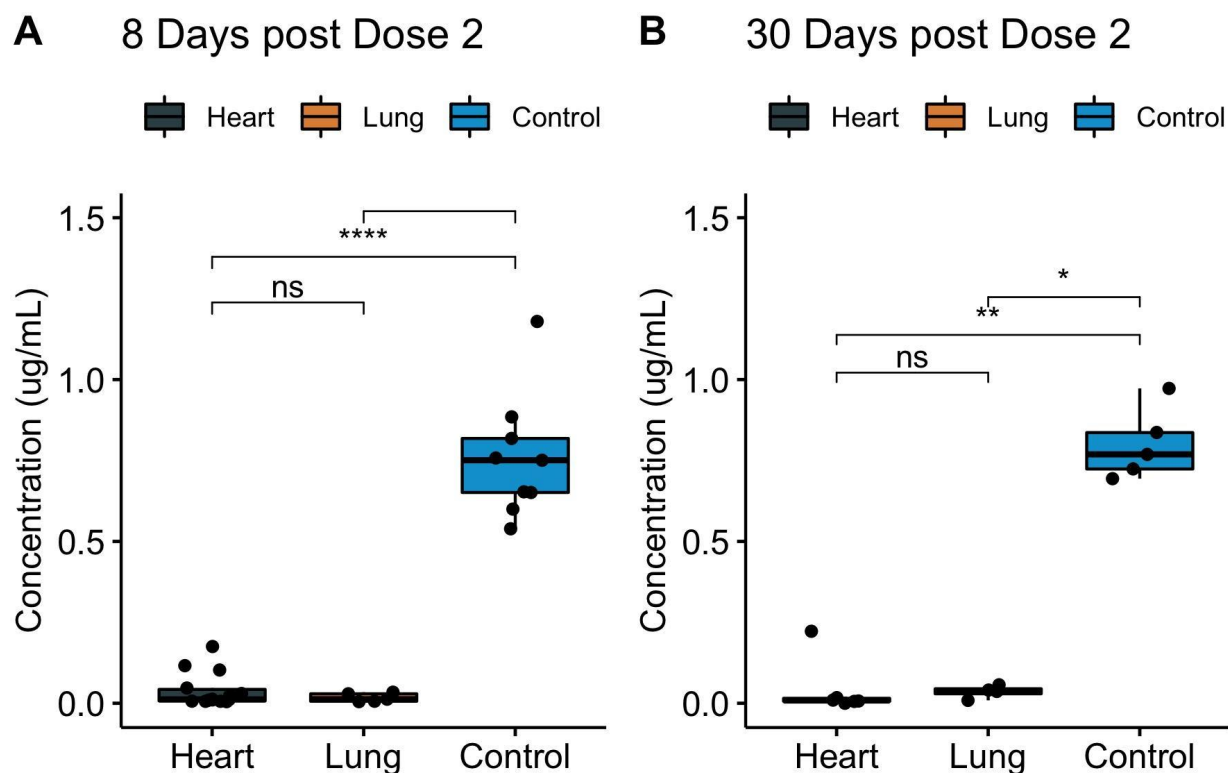

352 **Acknowledgments**

353 This work was supported by the American Lung Association COVID-19 Action Initiative
354 Research Award (to M.B.G.), the Cystic Fibrosis Foundation (to M.B.G.), Doris Duke Charitable
355 Foundation Physician-Scientist Fellowship (to J.E.L.), a CRI/Bristol Myers Squibb Postdoctoral
356 Fellowship (CRI 2993) (to M.G.), NIH U19 AI 110495 (to S.S.P.), and NIH UL1 TR 002541-01

362

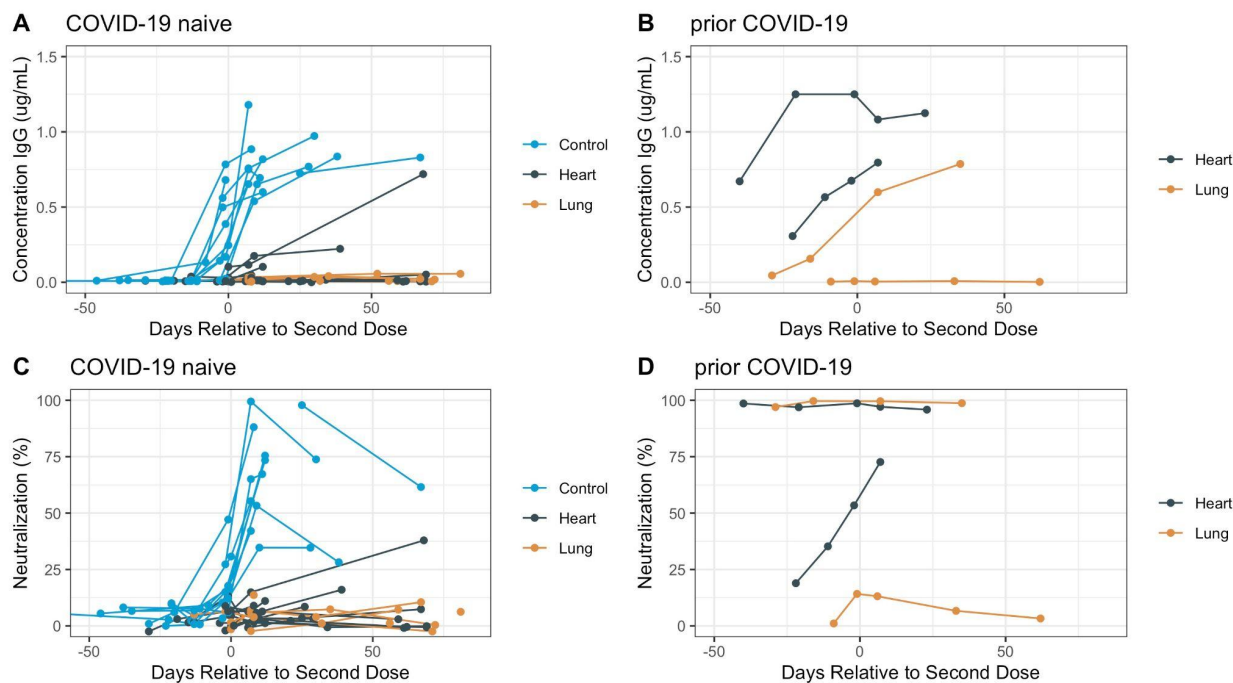

363

364 **Figure 1: Levels of serum IgG to SARS-CoV-2 spike protein RBD among fully vaccinated**
365 **COVID-19-naïve heart and lung transplant recipients.** Serum IgG binding to RBD, as
366 measured by ELISA, at 8 days (A) or 30 days (B) after full vaccination, displayed by
367 transplanted organ type. Data for the transplant recipients who had prior COVID-19 infection are
368 excluded. Boxes, 25th, 50th, and 75th percentile; whiskers, smallest and largest values in dataset
369 up to 1.5x interquartile range. All data points are shown. *, p < 0.05; **, p < 0.01; ****, p <
370 0.0001.

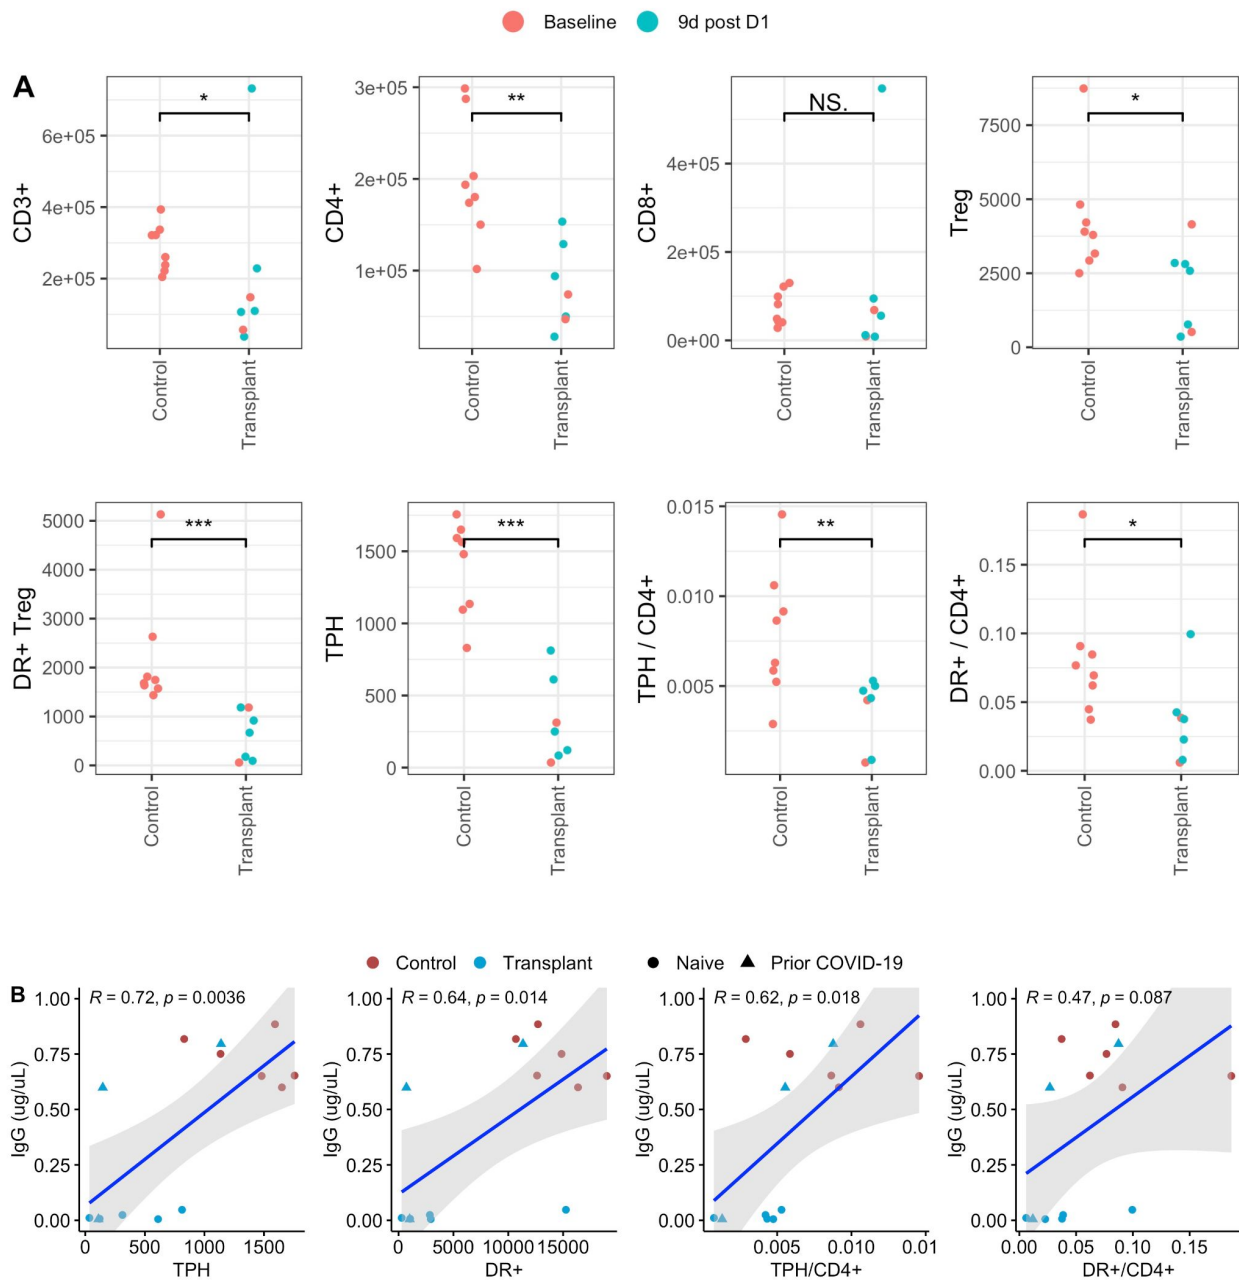

371

372 **Figure 2: Plasma pseudovirus neutralization activity among fully vaccinated COVID-19-**
373 **naive heart and lung transplant recipients.** SARS-CoV-2 neutralization, as measured by
374 pseudovirus neutralization assay, at 8 days (A) or 30 days (B) after full vaccination, displayed by
375 transplanted organ type. Data for the transplant recipients who had prior COVID-19 infection are
376 excluded. Boxes, 25th, 50th, and 75th percentiles; whiskers, smallest and largest values in dataset
377 up to 1.5x interquartile range. All data points are shown. *, p < 0.05; **, p < 0.01; ***, p <
378 0.001; ****, p < 0.0001.

379

380 **Figure 3: Antibody trajectories over time in individual subjects. (A-B)** IgG binding to
381 SARS-CoV-2 spike protein RBD over time, as measured by IgG ELISA, in COVID-19 naive
382 subjects (A) or in subjects with prior COVID-19 infection (B) displayed by transplanted organ
383 type. Neutralization activity over time in COVID-19 naive subjects (C) or in subjects with prior
384 COVID-19 infection (D). All data points are shown.

385

386

387 **Figure 4: Immune cell subsets and cellular correlates of antibody response. (A)**
 388 Quantification by flow cytometry of peripheral blood cells in COVID-19-naive individuals. **(B)**
 389 Correlation between antibody response at day 8 after complete vaccination and baseline levels of
 390 DR+ CD4 T peripheral helper (TPH) cells; DR+ CD4 T cells; DR+ CD4 T cells as a proportion
 391 of total CD4+ cells at baseline, or TPH cells as a proportion of total CD4+ cells at baseline.
 392 Least squares regressions (blue lines). Gray shading, 95% confidence interval (CI). *R*, correlation
 393 coefficient. All data points are shown. *, $p < 0.05$; **, $p < 0.01$; ***, $p < 0.001$; ****, $p <$
 394 0.0001.

395 Table 1. Demographic and clinical characteristics of cohort

Parameter	Range, description, or normal value	Transplant recipients			Healthy controls
		Heart (N=18)	Lung (N=8)	All (N=26)	
Age, median yrs. (range)		59 (41-76)	65 (35-76)	61 (35-76)	63 (37-74)
Female, n (%)		10 (56)	4 (50)	14 (54)	5 (42)
Race / ethnicity, n (%)	Hispanic	2 (11)	0 (0)	2 (8)	0 (0)
	Non-Hispanic	16 (89)	8 (100)	24 (92)	8 (67)
	Unknown	0 (0)	0 (0)	0 (0)	4 (33)
Years since transplant, n (%)	<1	3 (17)	1 (13)	4 (15)	n/a
	(1-5]	8 (44)	4 (50)	12 (46)	n/a
	(5-10]	1 (6)	1 (13)	2 (8)	n/a

	(10-15]	6 (33)	0 (0)	6 (23)	n/a
	≥15	0 (0)	2 (25)	2 (8)	n/a
Prior or concurrent COVID-19 infection, n (%)		2 (11)	2 (25)	4 (15)	0 (0)
Vaccine, n (%)	BNT162b2 (Pfizer-BioNTech)	15 (83)	8 (100)	23 (88)	9 (75)
	mRNA-1273 (Moderna)	2 (11)	0 (0)	2 (8)	3 (25)
	Ad26.COV2.S (Janssen)	1 (6)	0 (0)	1 (4)	0 (0)
Immunosuppressive medication regimen					
DNA synthesis inhibitor ^a		15 (83)	6 (75)	21 (81)	n/a
Calcineurin inhibitor ^b		18 (100)	7 (88)	25 (96)	n/a
mTOR inhibitor ^c		4 (22)	2 (25)	6 (23)	n/a
Prednisone, n (%)	none	2 (11)	0 (0)	2 (8)	n/a

	1-5 mg daily	14 (78)	1 (13)	15 (58)	n/a
	>5 to <10 mg daily	1 (6)	1 (13)	2 (8)	n/a
	≥10 mg daily	1 (6)	6 (75)	7 (27)	n/a

396 Abbreviations: n/a, not applicable. ^a Mycophenolate or azathioprine. ^b Tacrolimus or cyclosporine. ^c Evirolimus or
397 sirolimus.

398 Table 2. Surface markers used to define T and B cell subsets

Subset	Defining surface markers
Naive CD4+	CD3+CD4+CD8-CCR7+CD45RA+
Effector-memory CD4+	CD3+CD4+CD8-CCR7-
Regulatory T cells	CD3+CD4+CD8-CCR7-CD127LoCD25Hi
Activated regulatory T cells	CD3+CD4+CD8-CCR7-CD127LoCD25Hi HLA-DR+
Follicular helper T cells	CD3+CD4+CD8-CCR7-CD127+/-CD25+/-CXCR5+
Peripheral helper T cells	CD3+CD4+CD8-CCR7-CD127+/-CD25+/-CXCR5-CX3CR1-CD28+HLA-DR+PD1+
Naïve CD8+	CD3+CD4-CD8+CCR7+CD45RA+
Effector-memory CD8+	CD3+CD4-CD8+CCR7-
CD8+ cytotoxic T cells	CD3+CD4-CD8+CCR7-CX3CR1+CD28-
Naïve B cells	CD3-CD19+IgD+CD27-
Unswitched memory B cells	CD3-CD19+IgD+CD27+

Switched memory B cells	CD3-CD19+IgD-CD27+
Double negative B cells	CD3-CD19+IgD-CD27-
