37 **Abstract**

38

39 Determinants of Post-Acute Sequelae of COVID-19 are not known. Here we show that 75% of
40 patients with viral RNA in blood (RNAemia) at presentation were symptomatic in the post-acute
41 phase. RNAemia at presentation successfully predicted PASC, independent of patient
42 demographics, initial disease severity, and length of symptoms.

60 **Background**

61

62 The determinants of COVID-19 severity and extrapulmonary complications have now been well
63 studied, and RNAemia (viral RNA in blood) has emerged as an important factor (1,2). Much less
64 is known about the determinants of Post-Acute Sequelae of COVID-19 (PASC), the persistence
65 or development of new symptoms after the acute phase of infection, recently reported to affect as
66 many as 87.4% of COVID-19 patients (3,4) primarily with moderate or worse severity (5,6).
67 Recent evidence suggested persistent clotting protein pathology with elevated levels of
68 antiplasmin (7) and non-classical monocytes (8) in patients with PASC. Discovery of SARS-
69 CoV-2 S1 protein in these non-classical monocytes and fragmented SARS-CoV-2 RNA in
70 peripheral blood mononuclear cells in a PASC patient 15 months post infection further exhibited
71 the persistence of viral particles (8). Given the importance of RNAemia in disease severity and
72 its persistence in the blood, we describe the relationship between RNAemia at presentation and
73 post-acute symptoms at least three weeks after symptom onset.

74

75 **Methods**

76

77 We studied the clinical trajectories of 155 patients enrolled in the IRB-approved (eP-55650)
78 Stanford Hospital Emergency Department (ED) COVID-19 Biobank between April and
79 November 2020 with completed follow-ups. We assessed symptoms and severity (based on a
80 modified WHO scale) (1) on the date of enrollment (median = 4, range = 0 – 44 days after
81 symptom onset), and at least three weeks after symptom onset (median = 35, range = 21 – 79
82 days).

83

84 We measured SARS-CoV-2 RNAemia at the time of enrollment, using the definitions of our
85 earlier study (1). We compared the proportions of initially RNAemic and non-RNAemic patients
86 with persistent or new symptoms in the post-acute phase using a 2-sample chi-squared test with
87 continuity correction. We estimated the association between RNAemia at enrollment and PASC
88 at follow-up in a logistic model controlling for disease severity at enrollment, patient
89 demographics (age and gender), presence of any symptom at enrollment (anxiety, dizziness,
90 fatigue, hair loss, palpitations, rash, insomnia, chest pain, chills, cough, decrease in sense of
91 taste, fever, nausea/vomiting/diarrhea, headache, loss of smell, myalgia, new confusion,
92 shortness of breath), and durations of symptoms. We also compared the median number of PASC
93 symptoms for RNAemic and non-RNAemic patients using the Wilcoxon rank-sum test with
94 continuity correction. We performed all analyses in R (version 4.0.3).

95

96 **Results**

97

98 49.0% (76/155) of patients were women, and the median age was 45 years (IQR 34 – 60). At
99 enrollment, 27.1% (42/155) of patients had mild disease severity, 67.7% (105/155) moderate,
100 and 5.2% (8/155) severe. Patients had a median of six symptoms (IQR = 4–8): 72.3% (112/155)
101 had a cough, 65.3% (101/155) had shortness of breath, and 64.5% (99/155) had fever. In the
102 post-acute phase, 52.3% (81/155) had one or more new (24.5% [38/155]) or persistent (37.4%
103 [58/155]) symptoms, of which the most common were cough, dizziness, and loss of smell (Table
104 1). 1.3% (2/155) of patients developed anxiety that was not present at enrollment.

105

106 75.0% (27/36) of initially RNAemic patients were symptomatic in the post-acute phase,
107 compared to 43.7% (52/119) of non-RNAemic patients (difference = 31.3% [95% CI, 12.8% -
108 49.8%], $p=0.002$). RNAemic patients had a median of one symptom in the post-acute phase
109 compared to zero in non-RNAemic patients ($p=0.014$, Wilcoxon rank-sum test). RNAemia at
110 presentation predicted PASC, conditional on patient demographics and initial disease severity
111 (OR 1.31 [95% CI, 1.08 – 1.59], $p=0.007$ (Supplement)). The association was strongest for
112 patients with moderate disease severity at presentation (Figure), with 78.6% (22/28) of initially
113 RNAemic patients symptomatic in the post-acute phase, compared to 45.5% (35/77) of non-
114 RNAemic patients (difference = 33.1% [95% CI, 11.8% - 54.4%], $p=0.005$). This difference was
115 due almost entirely to persistent or new respiratory symptoms (difference in proportions = 28.2%
116 [95% CI, 8.4% - 47.9%], $p=0.002$).

117

118 **Discussion**

119

120 To our knowledge, this study describes the first reported association between SARS-CoV-2
121 RNAemia and PASC. RNAemia at presentation was associated with new or persistent symptoms
122 at least 21 days after symptom onset independent of initial patient severity and the association
123 was strongest among patients with moderately severe clinical presentations requiring hospital
124 admission. This finding adds to the growing literature on SARS-CoV-2 RNAemia's role in
125 disease severity and extrapulmonary complications in the acute phase of illness, as well as the
126 association between hospitalization and PASC (1,2,5,6). The incidence of PASC was lower in
127 this single-center study than in reports from Italy and the UK (3,4), but similar to that reported in
128 a recent study from the US (9). The potential contributions of patient characteristics, study

129 methodologies, and viral variants to these discrepancies merit further study. Though the
130 mechanisms underlying RNAemia's contributions to multi-system pathology in both the acute
131 and post-acute phases, when persistent, remain to be elucidated, mounting evidence for its
132 predictive value suggests that testing for SARS-CoV-2 RNAemia at presentation may help guide
133 the triage, management, and prognosis of COVID-19.
