

42 **Abstract (n = 200; max. 200 words)**

43

44 *Introduction:* We aimed to examine how public health policies influenced the dynamics of
45 COVID-19 time-varying reproductive number (R_t) in South Carolina from February 26, 2020 to
46 January 1, 2021.

47

48 *Methods:* COVID-19 case series (March 6, 2020 - January 10, 2021) were shifted by 9 days to
49 approximate the infection date. We analyzed the effects of state and county policies on R_t using
50 EpiEstim. We performed linear regression to evaluate if per-capita cumulative case count varies
51 across counties with different population size.

52

53 *Results:* R_t shifted from 2-3 in March to <1 during April and May. R_t rose over the summer and
54 stayed between 1.4 and 0.7. The introduction of statewide mask mandates was associated with a
55 decline in R_t (-15.3%; 95% CrI, -13.6%, -16.8%), and school re-opening, an increase by 12.3%
56 (95% CrI, 10.1%, 14.4%). Less densely populated counties had higher attack rate ($p < 0.0001$).

57

58 *Conclusion:* The R_t dynamics over time indicated that public health interventions substantially
59 slowed COVID-19 transmission in South Carolina, while their relaxation may have promoted
60 further transmission. Policies encouraging people to stay home, such as closing non-essential
61 businesses, were associated with R_t reduction, while policies that encouraged more movement,
62 such as re-opening schools, were associated with R_t increase.

63

64 **Keywords:** COVID-19, epidemiology, non-pharmaceutical interventions, mask mandate,
65 reproduction number

66 Introduction

67 In late December 2019, a novel virus was reported in Wuhan, China. By January 2020,
68 this virus had been identified as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-
69 2), the causative agent of coronavirus disease 2019 (COVID-19).¹ The disease was first reported
70 in the United States in January 2020.²

71 With an estimated population of 5,190,705, South Carolina is in the southeastern United
72 States, along the Atlantic coast, and shares borders with North Carolina and Georgia.³ South
73 Carolina reported the first case of COVID-19 in the state on March 6, 2020. On March 13, 2020,
74 the Governor of South Carolina declared a State of Emergency.⁴ By April 2, 2020, every county
75 in South Carolina had reported at least one case. Here we report on cases through January 10,
76 2021, by which point 361,254 cases had been reported, of whom 5,811 died.

77 Central to infectious disease epidemiology is the concept of the reproduction number (R_0)
78 – the average number of secondary cases that a primary case can infect absent any public health
79 intervention in a completely susceptible population.⁵ Before the appearance of the highly
80 transmissible Delta (B.1.617.2) variant, the R_0 for COVID-19 was estimated to lie between 2.2,⁶
81 and 4.4.⁷ In contrast, the time-varying reproduction number (R_t) describes the transmission
82 potential at a given timepoint as behavior changes and as public health interventions are
83 implemented.⁸ This makes R_t a better measure of disease spread over time as populations put
84 interventions into effect.^{9,10} Public health policies regarding non-pharmaceutical interventions
85 (NPIs) have been examined for their impact on the R_t .¹¹ South Carolina put various policies into
86 place from March 16, 2020, through October 5, 2020, primarily in the form of executive orders.

87 The purpose of this paper is to examine the change in the transmission potential of
88 SARS-CoV-2 in South Carolina over time, especially before and after state or county-level
89 public health policy interventions were put in place. We report the associations of R_t with these
90 policies.

91

92 Methods

93

94 This paper uses historic COVID-19 data from March 6, 2020 – January 10, 2021 from all
95 46 counties of South Carolina. South Carolina’s Department of Health and Environmental
96 Control divides the state into four regions: Upstate, Midlands, Pee Dee, and Low Country. A
97 map of all counties in South Carolina by health region is provided in **Supplemental Figure 1**.
98 Population by county is presented in **Supplemental Figure 2**. Cumulative case count and
99 cumulative case count per 100,000 population, in April, August, October and December 2020 are
100 presented in **Supplemental Figure 3**.

101 Information about policies enacted in South Carolina was obtained from Executive
102 Orders published online by the government of South Carolina. County level policies were
103 obtained from county health departments. Information about school openings was obtained from
104 school district websites, and in cases where schools had staggered openings (for example middle
105 schools starting before high schools), the earlier date was used. Detailed information on these
106 policies including the date of the implementation and relaxation of public health interventions is
107 presented in **Table 1**.

108

109 *Data acquisition*

110

111 From the New York Times GitHub repository,¹² we downloaded the cumulative
112 confirmed COVID-19 case count from March 6, 2020 - January 10, 2021. Data for the daily
113 incidence were cleaned at the county level to eliminate any dates with negative incidence
114 (**Appendix A**). We selected a starting point of March 6, 2020 since the first case in South
115 Carolina was reported on this date and a cutoff date of January 10, 2021 for all analyses. A nine-
116 day backward shift was used to estimate the date of infection, accounting for a 6-day incubation
117 period and a 3-day delay in testing. The error of this simple approach is considered tolerable if
118 the delay to observation is not highly variable and if the mean delay is known.⁸ This translated
119 into the assumed date of infection from February 26, 2020 to January 1, 2021. Our choice of the
120 cut-off point allowed us to complete the time series by the end of winter holiday season
121 (Christmas to New Year). A sensitivity analysis was conducted using a lower boundary of 4 days
122 and an upper boundary of 15 days based on incubation data reported by McAloon et al.,¹³ and
123 CDC reports on testing delays.¹⁴ We assessed the 2019 county-level population data for South
124 Carolina from the U.S. Census Bureau¹⁵ and examined the power-law relationship between
125 cumulative case count and population size through linear regression between the log₁₀-
126 transformed per capita cumulative case number and log₁₀-transformed population size for each
127 county.

128 129 *Statistical Analysis*

130
131 To calculate R_t , we used the instantaneous reproduction number method in the R package
132 *EpiEstim* with the parametric option. This measure of the R_t was defined by Cori et al.¹⁶ as the
133 ratio between I_t , the number of incident cases at the time t , and the total infectiousness of all
134 infected individuals at the time t . This R_t was used to describe the burden of COVID-19 at a state
135 level and throughout certain counties.

136 The R_t is presented in two ways in this paper. The first way is to take the average of the
137 daily R_t estimates over a 7-day sliding window. The second way is to take the average of the
138 daily R_t estimates over a non-overlapping time window between two time points of policy
139 changes (hereafter, known as policy change R_t in this paper).

140 The policy change R_t was used to establish associations with policies. We calculated the
141 percentage change for the policy change R_t for South Carolina (**Supplemental Table 1**), using
142 the median policy change R_t estimate at each policy interval. For instance, the median policy
143 change R_t estimate at each policy interval will be compared to the previous policy interval, as in
144 $100\% \times (t_2 - t_1) / t_1$. We utilized *EpiEstim sample from the posterior R distribution* function to obtain
145 a sample of 1000 estimates of R_t for each t_1 and t_2 then estimate the credible intervals (2.5 and
146 97.5 percentile) of the percentage change. We also calculated the percentage change of the policy
147 change R_t for Beaufort, Calhoun, Charleston, Colleton, Georgetown, Oconee, Orangeburg,
148 Richland, and Williamsburg counties in South Carolina (**Supplemental Table 2**). These nine
149 counties were selected because they are the only counties with an active mask ordinance during
150 the study period.

151 We characterized the power-law relationship between the county-level cumulative
152 number of COVID-19 cases and population size, following $C \sim N^g$ (C , cumulative case count; N ,
153 population size; g , exponent).¹⁷ We performed linear regression analysis between the log₁₀-
154 transformed per capita cumulative case count and the log₁₀-transformed population size, i.e.,
155 $\log_{10}(C/N) = m \log_{10}(N)$ where $m = g - 1$.¹⁷⁻¹⁹ We computed linear regression between the log₁₀-

156 transformed per capita cumulative case count and the \log_{10} -transformed population size, at four
157 different dates: June 30th, August 31st, October 31st, and December 31st.

158 When per capita cumulative case count is proportional to population size, then there was
159 no heterogeneity of per capita cumulative case count across geographic units (counties) of
160 different population sizes (i.e., when $m=0$ and thus $g=1$). Geographical units with lower
161 population sizes would have a higher per capita cumulative case count if $m<0$ (i.e., $g<1$) and
162 those with lower population sizes would have a lower per capita cumulative case count if $m>0$
163 (i.e., $g>1$).^{18,19} See **Appendix B** for details.

164 Statistical analysis was performed using R 4.0.3 (R Core Team, R Foundation for
165 Statistical Computing, Vienna, Austria). **Supplemental Figures 1, 2 and 3** were created using R
166 3.5.1 (R Core Team, R Foundation for Statistical Computing, Vienna, Austria).

167 168 *Ethics*

169 The Georgia Southern University Institutional Review Board made a non-human subject
170 determination for this project (H20364) under the G8 exemption category according to the Code
171 of Federal Regulations Title 45 Part 46.

172 173 174 **Results**

175 176 *State Level - General*

177 The daily new case count rose at the beginning of June 2020, and the peak of the first
178 wave of cases arrived by mid-July. Case counts then started falling but remained higher than the
179 beginning of the pandemic. By late September, case count rose again, and continued to rise
180 through the end of the study period. Several days were reported with 0 cases, as data was not
181 reported on federal holidays (Thanksgiving, Christmas Day, and New Year's Day). **Figure 1**
182 displays daily incident case count, 7-day sliding window R_t , and the policy change R_t , all right-
183 adjusted for nine days at the state level. The 7-day sliding window R_t throughout the state
184 fluctuated between 2 and 3 in early March, and decreased to <1 during parts of April and May
185 2020. Over the summer, the R_t rose and continued to fluctuate between 0.7 and 1.4 throughout
186 the state. At the end of the study period, the R_t was still above 1.0 indicating continued spread of
187 the virus.

188 189 *Policy Impacts – State Level*

190
191 R_t fluctuated with policy changes at the state level. The R_t presented in this section refers
192 to the policy change R_t . (**Figure 1**: lower panel, **Supplemental Table 1**). Prior to the
193 introduction of any policies, the R_t was 1.991 (95% credible interval, CrI, 1.787, 2.21). The first
194 policy introduced was the closure of schools on March 16th.²⁰ Between the closure of schools and
195 the closure of non-essential businesses, the R_t was 1.285 (95% CrI, 1.24, 1.33), a decrease of
196 35.59% (95% CrI, 27.9%, 42.7%).

197 The closure of non-essential businesses was ordered on April 3,²¹ indicated by the label
198 'N' in **Figure 1**. R_t dropped to 1.028 (95% CrI, 1.01, 1.05), a decrease of 20.01% (95% CrI,
199 18.8%, 21.1%), although the policy window was short. Some non-essential businesses were
200 allowed to begin re-opening on May 22, following the issue of Executive Order 37.²² The R_t

201 associated with this timeframe was 1.05 (95% CrI, 1.04, 1.06), a statistically insignificant
202 increase of 2.07% (95% CrI, -0.217 %, 4.2%).

203 The next Executive Order we examined was passed on August 2, 2020 mandating masks
204 in government building, restaurants, and large venues.²³ This was associated with the first
205 occurrence of R_t dropping below 1.0 in our policy examination. During this timeframe, the R_t
206 was 0.889 (95% CrI, 0.873, 0.905), a decrease of 15.3% (95% CrI, 13.6%, 16.8%).

207 Our proxy date for school openings was August 17, 2020. This was based on the earliest
208 reported dates for school openings. The R_t rose following this date to 0.998 (95% CrI, 0.989,
209 1.01), an increase of 12.3% (95% CrI, 10.1%, 14.4%). The final policy in this analysis was
210 enacted on October 2, allowing restaurants to reopen for indoor dining and lifting capacity
211 limits.²⁴ This was followed by an increase in R_t to 1.098 (95% CrI, 1.09, 1.1), increasing by
212 9.994% (95% CrI, 9.47%, 10.5%). This indicated sustained transmission of COVID-19 in South
213 Carolina.

214 Sensitivity analysis was conducted to examine the effect of the assumption of the time
215 lag. A 15-day time lag (**Supplemental Figure 4**) and a 4-day time lag (**Supplemental Figure 5**)
216 were applied to the time series of the state-level case count data and no major differences
217 between the main results and the lagged results were observed.

218
219

220 *Mask Mandates – County Level*

221

222 The wearing of masks has been advised for the general public since early April of 2020.²⁵
223 However, the requirement for face mask wearing was left up to each state, likely due to the
224 federal polity of the U.S. and the political atmosphere in 2020.²⁶ For the purposes of this paper a
225 “mask mandate” is any order given by authority for residents of a certain area to wear a mask or
226 face covering while in specified locations. In South Carolina, the first Executive Order to
227 mandate masks was issued on August 3, 2020.²⁰ This Order only mandated masks in government
228 buildings, restaurants, and large venues.

229 Several counties (Beaufort, Charleston, Georgetown, Orangeburg, Richland, and
230 Williamsburg) issued their own mask mandates before the state. Three counties (Calhoun,
231 Colleton, and Oconee) issued a mask mandate after the statewide order was passed. We showed
232 the policy change R_t for these counties in **Figure 2** and **Figure 3**. These nine counties were the
233 only counties with an active mask ordinance during the study period (**Supplemental Table 2**).

234 The first counties we examined were those that passed the county-level mask ordinance
235 before the state mandate. Beaufort county passed its ordinance on July 3rd 2020.²⁷ The R_t
236 decreased from 1.2283 (95% CrI, 1.17, 1.29) to 0.9856 (95% CrI, 0.946, 1.027), a decrease of
237 19.76% (95% CrI, 16.7%, 22.9%). Charleston county passed its first mask ordinance on July 1st,
238 2020.²⁸ After the county ordinance passed, the R_t dropped from 1.2526 (95% CrI, 1.22, 1.28) to
239 0.8774 (95% CrI, 0.855, 0.90), decreasing by 29.95% (95% CrI, 29.9%, 30.0%). Georgetown
240 County’s mask ordinance passed on July 3rd, 2020.²⁹ The R_t decreased to 0.9596 (95% CrI,
241 0.891, 1.032) from 1.1980 (95% CrI, 1.11, 1.29), a decrease of 19.89% (95% CrI, 12.8%,
242 26.5%). Orangeburg County passed its Face Mask Ordinance on July 3rd, 2020,³⁰ and its R_t
243 estimates decreased from 1.2002 (95% CrI, 1.13, 1.28) to 0.9585 (95% CrI, 0.908, 1.011) with a
244 decrease of 20.16% (95% CrI, 13.5%, 26.7%). Richland County passed its Face Mask Ordinance
245 on July 6th, 2020,³¹ and its R_t estimates decreased from 1.1729 (95% CrI, 1.14, 1.21) to 0.9529
246 (95% CrI, 0.922, 0.984), a decrease of 18.76% (95% CrI, 18.7%, 18.8%). Finally, Williamsburg

247 County's R_t decreased after the introduction of their mask mandate on July 9th, 2020,³² from
248 1.1342 (95% CrI, 1.02, 1.26) to 1.0013 (95% CrI, 0.912, 1.069), a decrease of 11.75% (95% CrI,
249 1.1%, 21.4%).

250 Calhoun, Colleton, and Oconee counties had their county level mask mandates passed
251 after the August 3rd state mask mandate (**Figure 3**, top panel). Among them, Oconee County
252 passed a county-level mask ordinances on August 18th before the school re-opening.³³ After the
253 county-level mandate passed, the R_t further decreased from 1.0591 (95% CrI, 0.901, 1.235) to
254 1.0259 (95% CrI, 0.89, 1.17), a decrease of 3.16% (95% CrI, 1.21%, 4.91%). However, Calhoun
255 County and Colleton County passed their county-level face mask ordinances much later than the
256 state level mask mandate and months after the schools reopened in the Fall. Colleton County
257 passed the county-level face mask ordinances on November 10th, 2020,³⁴ and the R_t increased by
258 9.0% (95% CrI: -0.719%, 19.01%) from 1.0353 (95% CrI: 0.943, 1.133) to 1.1287 (95% CrI:
259 1.05, 1.21), but the increase was statistically insignificant. Lastly Calhoun County passed their
260 county-level face mask ordinances on December 18th, 2020,³⁵ and the R_t increased from 1.0737
261 (95% CrI: 0.965, 1.19) to 1.101 (95% CrI: 0.941, 1.278), but the increase of 2.82% (95% CrI, -
262 12.8%, 22.0%) was statistically insignificant.

263 264 *School Openings*

265
266 School openings were examined in both **Figures 1, 2** and **3**. In **Figure 1**, school re-
267 opening is indicted by label 'S', where we used a proxy date of August 17th, the earliest reported
268 school opening date across the state. It is important to note that these school openings are based
269 on K through 12 schools' starting dates and not college starting dates. Some schools reopened in
270 a staggered way by grade. Following school openings, the R_t in South Carolina rose by 12.3%
271 (95% CrI, 10.1%, 14.4%) from 0.889 (95% CrI, 0.873, 0.91) to 0.998 (95% CrI, 0.989, 1.01).

272 At the county level (**Figures 2 and 3**), R_t increased when schools were re-opened in most
273 counties. In Beaufort County, the increase was 22.57% (95% CrI, 16.7%, 27.7%) from 0.8903
274 (95% CrI, 0.839, 0.944) to 1.0916 (95% CrI, 1.06, 1.12). Calhoun County's R_t increased from
275 0.6857 (95% CrI, 0.461, 0.974) to 1.0737 (95% CrI, 0.965, 1.19), an increase of 56.29% (95%
276 CrI, 9.66%, 127.21%). In Charleston County, the R_t rose by 13.03% (95% CrI, 10.9%, 15.1%)
277 from 0.9621 (95% CrI, 0.927, 0.998) to 1.0878 (95% CrI, 1.07, 1.11). The Colleton County R_t
278 increased by 17.77% (95% CrI, -1.33%, 38.12%) from 0.8782 (95% CrI, 0.74, 1.03) to 1.0353
279 (95% CrI, 0.943, 1.133), but the increase was statistically insignificant. The R_t in Georgetown
280 County rose from 0.8468 (95% CrI, 0.762, 0.937) to 1.1016 (95% CrI, 1.06, 1.14), increasing by
281 29.9% (95% CrI, 15.6%, 45.1%).

282 Oconee County had a statistically insignificant increase of 4.25% (95% CrI, -9.85%,
283 20.29%) in R_t from 1.0259 (95% CrI, 0.89, 1.17) to 1.0710 (95% CrI, 1.04, 1.11). Orangeburg
284 County had an increase in R_t from 0.8447 (95% CrI, 0.763, 0.932) to 1.0972 (95% CrI, 1.06,
285 1.14), an increase of 29.67% (95% CrI, 16.0%, 44.1%). In Richland County, the R_t increased
286 slightly from 1.0434 (95% CrI, 1.01, 1.08) to 1.0439 (95% CrI, 1.03, 1.06), but the increase of
287 0.016% (95% CrI, -1.78%, 1.79%) was statistically insignificant. Williamsburg County's R_t
288 increased to 1.1264 (95% CrI: 1.07, 1.19) from 0.8692 (95% CrI: 0.767, 0.98), an increase of
289 29.54% (95% CrI: 12.4%, 48.3%).

290 291 *Power-law Relationship between Cumulative Case Number and Population Size*

292

293 **Figure 4** presents the linear regression models between the \log_{10} -transformed per capita
294 cumulative case number and the \log_{10} -transformed population size for a total of 46 counties in
295 South Carolina at four different dates of report, June 30th, August 31st, October 31st, and
296 December 31st, 2020, respectively. Each regression line represents a specific assessed date (date
297 of report); and the slopes, m , of four regression lines were calculated and documented in **Table**
298 **2**. Slopes of four regression lines were negative ($m < 0$) and statistically significant ($m = -2.0236$,
299 -1.2164 , -1.0220 , -1.0577 ; $p < 0.0001$ respectively). A negative slope suggests that counties with
300 lower population sizes (i.e., rural counties) would have a higher per capita cumulative case
301 count. This result suggests the existence of potential health disparities between urban and rural
302 counties.

303 304 **Discussion**

305
306 This paper examined the associations between SARS-CoV-2 R_t and public health policy
307 changes throughout South Carolina from February 2020 to January 2021. We specifically
308 examined the impacts of mask mandates at a county level and the resumption of in-person school
309 activities (**Figures 2 and 3**). We found that mask mandates were frequently associated with a
310 decrease in R_t while school re-openings were frequently associated with an increase in R_t .

311 We found that in Beaufort, Charleston, Georgetown, Oconee, Orangeburg, Richland, and
312 Williamsburg counties, where a mask mandate was introduced at the county level prior to the
313 state level mandate, a decrease in R_t was associated with the introduction of the policy. This
314 suggested that county-level facemask mandate did have its utility in dampening SARS-CoV-2
315 transmission. In Oconee County, the state-level facemask mandate happened before the county-
316 level facemask mandate. The county-level mandate apparently led to a slight further decrease in
317 R_t .

318 In two counties, Calhoun and Colleton, the introduction of a county-level mask mandate
319 happened late in 2020, after the introduction of the state-level mask mandate and the re-opening
320 of schools. In both cases, R_t dropped below 1 after the state mask mandate but increased to levels
321 above 1 after schools reopened. Our results suggest that the county-level mandates were
322 introduced too late to have a significant impact on R_t . The increased R_t after the county-level
323 mask mandate should be interpreted as a continuation of an increase in R_t despite the county-
324 level mask mandate. Additionally, by late 2020 adherence fatigue³⁶ might also impact how well
325 facemask mandates were followed.

326 We also examined school re-openings in counties that had county level mask mandates in
327 place (**Figures 2 and 3**). In these counties, the R_t fell when the county mask mandate was put in
328 place. In most places the R_t lowered again when the state mandate was put into place, although in
329 Charleston and Richland counties the R_t did rise after the state mandate. This may be due to
330 adherence fatigue³⁷ in the summer months. Richland county includes Columbia, the state capital.
331 Columbia is highly populated and is the site of the University of South Carolina main campus.
332 Case counts here might be impacted by the university opening (such as student parties that
333 turned out to be super-spreading events).³⁸ Charleston is a tourist destination, so potentially an
334 increase in late summer tourism could have driven the R_t higher despite the statewide mask
335 mandate, especially as the mandate only required masks in government buildings, restaurants, or
336 large venues. Similar observations can be said of Beaufort County, where the tourist destination
337 Hilton Head Island is located. While the county's and state's mask mandates were associated
338 with R_t decreasing to below 1 in Beaufort, R_t increased after school re-opening in September.

339 Other literature supports the notion that mask mandates may slow the transmission of
340 SARS-CoV-2.³⁹ Hua et al. found that a mask mandate was associated with a decrease in R_t by
341 27% in North Dakota, by 16% in Montana and by 13% in Wyoming.⁴⁰ Politis et al. found
342 facemask mandate was associated with a decrease in R_t by 11% and 6%, respectively, in
343 Arkansas and Kentucky.¹⁰ Thus, our findings in South Carolina are consistent with findings in
344 other states that a mask mandate was associated with slowing epidemic growth.

345 The role of school re-openings in COVID-19 transmission has been examined as
346 well.^{37,41-44} A high school in Israel reported a COVID-19 outbreak shortly after a school
347 reopened in May 2020.⁴² Another study modeled school re-opening, and found that reduction in
348 capacity and mask wearing could reduce community transmission, whereas higher capacity and
349 non-adherence to mask wearing could drive COVID-19 spread in the school's community.⁴⁴
350 According to our analyses (**Figures 2 and 3**), the percentage changes of policy change R_t
351 estimates increased in eight of nine selected counties, except Richland County. This observation
352 echoes existing studies that school re-openings have the potential to spread COVID-19 in the
353 local communities.^{37,42-44} Similar to our findings, Hua et al. found an increase in R_t in Idaho
354 (13%), Montana (21%), South Dakota (12%) and Wyoming (20%) after school reopened on
355 September 7, 2020; however, the same study found a decrease in R_t by 8% in North Dakota after
356 school re-opening on the same date.⁴⁰ Politis et al. found that after school reopened, R_t increased
357 by 12% and 9% in Arkansas and Kentucky, respectively.¹⁰ Thus, our findings in South Carolina
358 are consistent with findings in other states in general, that school re-opening in August and
359 September 2020 was associated with increased SARS-CoV-2 transmission as evidenced in an
360 increase in R_t .

361 In addition, rural counties in South Carolina were found to have a higher per capita
362 cumulative case count at four different assessed dates in 2020. This result suggests that rural
363 counties bore a higher disease burden than urban counties. Future research may investigate the
364 cause and related factors of such health disparities.

365 The focus of this study was on public health and social policy involving mandates of
366 NPIs. Our study period ended in early 2021 before the vaccination campaign could make an
367 impact to slow SARS-CoV-2 transmission in South Carolina. Future research may study whether
368 certain highly transmissible variants of concern may trigger COVID-19 resurgence.⁴⁵ While this
369 is out of scope for this study, further research into the effect of policy mandates that target
370 special populations such as residents of long-term care facilities and their caretakers may be
371 conducted.⁴⁶

372 373 *Limitations*

374 There are a number of limitations in this study. First, this analysis was based on
375 aggregate data reported by the surveillance system of COVID-19 in South Carolina. The data
376 was arranged by date of report. Even though we shifted the date backward by 9 days to
377 approximate the date of infection, this remained an estimation. Second, date of report is affected
378 by holidays, on which days cases were not reported. Third, the effects of viral variants on
379 transmission potential⁴⁵ cannot be shown in this study. The first two cases of the Beta (B.1.351)
380 variant in the U.S. were detected in South Carolina after the study period ended,⁴⁷ so this may
381 not be a severe limitation. Fourth, while re-opening of schools was staggered by grade in South
382 Carolina, we lumped the re-openings together as we chose the first date of the re-opening as the
383 date of policy change. However, for the county-level policy change analysis, we had specific
384 school re-opening dates for all nine selected counties (**Figures 2 and 3**). And finally, we do not

385 examine the impact of vaccinations on the transmission potential in South Carolina; however,
386 our study period ended by January 10th, 2021 (date of report), by which point there were minimal
387 numbers of people fully vaccinated.

388 Although we examined the impact of policy mandates, we did not examine the extent to
389 which these policies were adhered on the ground. Behavioral variation in some places might
390 impact the effectiveness of policies. However, as we attempted to examine the real-world effects
391 of interventions on COVID-19 transmission potential, this would not be a serious limitation to
392 the paper.

393 394 *Conclusions*

395 The pandemic affected South Carolina starting with the first cases confirmed in early
396 March 2020, and data suggest ongoing transmission from late February 2020 through the end of
397 the study period (the beginning of 2021). Our findings suggest that public health policies that
398 encourage the adoption of NPIs, such as mask mandates, were found to be associated with a
399 decrease in R_t . In contrast, policies that encouraged more social interaction and population
400 movement, such as re-opening schools for in-person instruction, were typically followed by an
401 increase in R_t . In general, mask mandates appeared to work better in counties that implemented it
402 early on than those that implemented it after the incidence trajectory had risen to a high level.
403 Our paper provided a state and county-level analysis that could support evidence-based decision-
404 making in the adoption of NPIs at the population level against COVID-19. Our findings could
405 prove useful for shaping future outbreak responses.

Appendix A: Handling of negative incident case count

A negative incident case count means the daily number of new cases reported being negative. This happened when the local public health department made an adjustment to the previously reported data by removing the duplicated cases or cases introduced by human errors. This usually resulted in a cumulative case count of the day being lower than the cumulative case count of the previous day, which translates into a negative incident case count. When negative cases appeared in the downloaded data, we used the previous day's case data to bring the negative incidence to zero. In the instance when the previous day did not have enough cases to make the negative incidence zero, we worked backward until there were enough cases brought to the negative case count to equal it to zero.

Appendix B: Cumulative case count and Population size of a County

The power-law relationship between the county-level cumulative number of COVID-19 cases and population size can be transformed into a linear relationship between the \log_{10} -transformed cumulative case count and the \log_{10} -transformed population size as follows^{1,2}:

$$\begin{aligned}C &= N^g \\ \log_{10} C &= g \log_{10} N \\ \log_{10} C - \log_{10} N &= g \log_{10} N - \log_{10} N \\ \log_{10}(C/N) &= (g - 1) \log_{10} N \\ \log_{10} A &= m \log_{10} N\end{aligned}$$

where the per capita cumulative case count $A=C/N$ and the slope of the regression line, $m = g-1$.

In this paper, we performed linear regression models between \log_{10} -transformed per capita cumulative case count and \log_{10} -transformed population size of counties in South Carolina. The data analyzed were by the dates of report of June 30, August 31, October 31 and December 31, 2020. If the slope m is positive, it implies that counties with higher populations (i.e., urban counties) had a higher attack rate. If the slope is negative, it implied that counties with lower populations (i.e., rural counties) had a higher attack rate. If the slope is 0 (or if the 95% confidence interval includes 0), it implied that the attack rate was the same across the counties regardless of their population size.
