29 **Abstract**

30

31 Little is known about the genetics of norm violation and aggression (ASB) in relation to coronavirus
32 disease 2019 (COVID-19). To investigate this, we used summary statistics from genome-wide
33 association studies and linkage disequilibrium score regression to calculate a matrix of genetic
34 correlations (r_{gs}) for ASB, COVID-19, and various health and behavioral traits. After false-discovery
35 rate correction, ASB was genetically correlated with COVID-19 ($r_g = 0.51$; $P = 1.54E-02$) and 19 other
36 traits. ASB and COVID-19 were both positively genetically correlated with having a noisy workplace,
37 doing heavy manual labor, chronic obstructive pulmonary disease, and genitourinary diseases. ASB
38 and COVID-19 were both inversely genetically correlated with average income, education years,
39 healthspan, verbal reasoning, lifespan, cheese intake, and being breastfed as a baby. But keep in mind
40 that r_{gs} are not necessarily causal. And, if causal, their prevailing directions of effect (which causes
41 which) are indiscernible from r_{gs} alone. Moreover, the SNP-heritability (h_g^2) estimates for both
42 measures of COVID-19 were very low, restricting the overlap of genetic variance in absolute terms
43 between the two traits. Nonetheless, our findings suggest that those with antisocial tendencies possibly
44 have a higher risk of exposure to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) than
45 those without antisocial tendencies. This may have been especially true early in the pandemic before
46 vaccines against SARS-CoV-2 were available and before the emergence of the highly transmissible
47 Omicron variant.

48

49

50

51

52 **Introduction**

53 Antisocial behavior (ASB)— including aggression, rule-breaking, delinquency, and violence—
54 are harmful to society. ASB creates a long wake of monetary, social, and emotional disturbances for
55 countries, communities, and individuals^{1,2}. Especially troublesome are the possible effects during
56 pandemics. For instance, ASB may abet pandemic spread. Those engaged in overt ASB seem to adhere
57 less to coronavirus disease 2019 (COVID-19) containment measures³⁻⁵. Similarly, individuals scoring
58 higher on less obvious indicators of antisociality (i.e., low acceptance of moral rules, higher levels of
59 psychopathy, “pre-pandemic legal cynicism, low shame/guilt, low self-control, engagement in
60 delinquent behaviors, and association with delinquent peers”) have shown evidence of disregarding
61 public-health guidelines^{3,4,6}. This warrants further investigation into the possible connections between
62 ASB and exposure to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the virus that
63 causes COVID-19.

64 Complicating causal inference concerning the links between of ASB and pandemic-relevant
65 outcomes is that about half of the variance in ASB and, to varying degrees, associated traits, is
66 heritable⁷⁻⁹. This matters because the extent to which ASB and other traits share genetic architecture
67 could influence the likelihood of genetic confounding in observational studies. Broadly addressing this
68 problem is a nascent area of research that uses genome-wide association (GWA) studies of ASB and
69 various health and behavioral traits to calculate genetic correlations (r_{gs})¹⁰. These studies have revealed
70 r_{gs} between ASB and most psychiatric, psychological, reproductive, cognitive, and addictive traits^{11,12}.
71 In addition, those prone to antisocial, violent, and criminal behaviors are disproportionately and
72 profoundly unhealthy^{13,14}. A strongly negative genetic correlation ($r_g = -0.55$) between ASB and self-
73 reported health has been reported¹¹. In contrast, a comprehensive study found no significant r_{gs}
74 between ASB and 669 health, physiological, and well-being measures after accounting for multiple

75 testing¹⁵. Thus, much remains to be discovered regarding shared etiology between ASB and various
76 aspects of health, including COVID-19.

77 **Methods and materials**

78 We characterized the shared polygenic nature of ASB, COVID-19, and various health and
79 behavioral traits using summary statistics from GWA studies and linkage disequilibrium score
80 regression (LDSC; software available at <http://www.github.com/bulik/ldsc>)¹⁶. We calculated a matrix
81 of r_{gs} . Of note is that correlation, even when genetic, is not necessarily causation. While our study can
82 point to shared genetic architecture between traits, the reader should be cautious about assuming that
83 the r_{gs} are causal. **Table 1** contains details about the GWA studies we used and where interested
84 researchers can access them. Nineteen traits were chosen for novelty (having not been previously
85 reported as either null or significantly correlated with ASB). The novel traits include: average income
86 (before taxes); healthspan (i.e., living free from congestive heart failure, myocardial infarction, chronic
87 obstructive pulmonary disease [COPD], stroke, dementia, diabetes, cancer, and death; coded as a
88 protective ratio); parental lifespan (hereafter “lifespan”; coded as a protective ratio); word interpolation
89 (hereafter “verbal reasoning”); having been breastfed as baby; cheese intake; self-reported happiness;
90 having had COVID-19 (data from two GWA studies); doing heavy manual labor; having a noisy
91 workplace; Townsend Deprivation Index (an area- and census-based measure of deprivation, where a
92 higher score indicates more deprivation); having gastrointestinal diseases; having COPD; having
93 genitourinary diseases; playing computer games; having been a violent-crime victim; risk tolerance,
94 and witnessing a sudden violent death. Four traits (education years; seen doctor for nerves, anxiety,
95 tension, or depression; neuroticism; and Parkinson's disease) were chosen as replicates of previously
96 reported findings.

97 **Results**

98 **ASB**

99 After false-discovery rate (FDR)-correction ($P < 0.05$), ASB was positively genetically
100 correlated with COVID-19 (release 4): $r_g = 0.51$; $P = 1.54E-02$. The r_g was also positive between ASB
101 and COVID-19 (release 6) with marginal significance *prior* to FDR-correction but not after: $r_{gs} = 0.35$;
102 $P = 3.83E-02$ (FDR-corrected $P = 5.21E-02$). The remaining (FDR-significant) r_{gs} between ASB and
103 health and behavioral traits that were positive are as follows:

- 104 1. Townsend Deprivation Index ($r_g = 0.70$)
- 105 2. Noisy workplace ($r_g = 0.63$)
- 106 3. Heavy manual labor ($r_g = 0.58$)
- 107 4. COPD ($r_g = 0.51$)
- 108 5. Risk tolerance ($r_g = 0.50$)
- 109 6. Gastrointestinal diseases ($r_g = 0.46$)
- 110 7. Seen a doctor for nerves, anxiety, tension, or depression ($r_g = 0.42$)
- 111 8. Seen a sudden violent death ($r_g = 0.42$)
- 112 9. Genitourinary diseases ($r_g = 0.38$)
- 113 10. Being a violent-crime victim ($r_g = 0.36$)
- 114 11. Neuroticism ($r_g = 0.29$)
- 115 12. Playing computer games ($r_g = 0.15$)

116 ASB was negatively genetically correlated with seven traits (after FDR-correction):

- 117 1. Average income ($r_g = -0.54$)
- 118 2. Education years ($r_g = -0.48$)
- 119 3. Healthspan ($r_g = -0.47$)

120 4. Verbal reasoning ($r_g = -0.44$)

121 5. Lifespan ($r_g = -0.33$)

122 6. Cheese intake ($r_g = -0.28$)

123 7. Breastfed as baby ($r_g = -0.24$)

124 The r_{gs} for ASB and the health and behavioral traits are displayed in a forest plot in **Figure 1** and

125 presented in **Table 2** along with confidence intervals and SNP-heritability (h_g^2) estimates. See the

126 Supplement for the results for all the r_{gs} in the matrix (Supplementary Table 1), including the p -values

127 before and after FDR-correction (Supplementary Table 2).

128 **COVID-19**

129 Due to the positive r_g between COVID-19 and ASB, we highlight the FDR-significant r_{gs}

130 between COVID-19 and non-ASB traits. COVID-19 was positively genetically correlated with the

131 following:

132 1. COPD ($r_g = 0.40$) -- COVID-19 (release 6)

133 2. COPD ($r_g = 0.33$) -- COVID-19 (release 4)

134 3. Heavy manual labor ($r_g = 0.38$) -- COVID-19 (release 6)

135 4. Heavy manual labor ($r_g = 0.20$) -- COVID-19 (release 4)

136 5. Genitourinary diseases ($r_g = 0.32$) -- COVID-19 (release 6)

137 6. Noisy workplace ($r_g = 0.28$) -- COVID-19 (release 6)

138 7. Noisy workplace ($r_g = 0.26$) -- COVID-19 (release 4)

139 COVID-19 was negatively genetically correlated with the following:

140 1. Cheese intake ($r_g = -0.39$) -- COVID-19 (release 6)

141 2. Cheese intake ($r_g = -0.36$) -- COVID-19 (release 4)

- 142 3. Education years ($r_g = -0.46$) -- COVID-19 (release 6)
- 143 4. Education years ($r_g = -0.32$) -- COVID-19 (release 4)
- 144 5. Verbal reasoning ($r_g = -0.49$) -- COVID-19 (release 6)
- 145 6. Verbal reasoning ($r_g = -0.28$) -- COVID-19 (release 4)
- 146 7. Healthspan ($r_g = -0.41$) -- COVID-19 (release 6)
- 147 8. Healthspan ($r_g = -0.25$) -- COVID-19 (release 4)
- 148 9. Breastfed as baby ($r_g = -0.24$) -- COVID-19 (release 6)
- 149 10. Lifespan ($r_g = -0.30$) -- COVID-19 (release 6)
- 150 11. Average income ($r_g = -0.21$) -- COVID-19 (release 6)

151 Notably, ASB and COVID-19 were both positively genetically correlated with having a noisy
152 workplace, doing heavy manual labor, COPD, and genitourinary diseases. They were both inversely
153 genetically correlated with average income, education years, healthspan, verbal reasoning, lifespan,
154 cheese intake, and being breastfed as a baby. The r_{gs} between COVID-19 and the non-ASB traits are
155 presented in **Figure 2** and **Table 3** along with confidence intervals and h_g^2 estimates.

156 **Discussion**

157 In support of prior observational findings by O'Connell *et al.* (2021)⁵, Carvalho and Machado
158 (2020)³, Miguel *et al.* (2021)⁴, and Nivette *et al.* (2020)⁶, the positive r_g between ASB and COVID-19
159 suggests that those with antisocial tendencies are more likely to be exposed to SARS-CoV-2 than those
160 who do not engage in ASB. Although ASB is generally associated with impulsive and risk-taking
161 proclivities, the r_g between COVID-19 and risk tolerance was null in our study, a result that argues
162 against a propensity for risk-taking behavior underlying the link between ASB and exposure to SARS-
163 CoV-2. The totality of our data instead suggests that a broad architecture of factors predispose some to

164 both ASB and COVID-19. Traits, for example, that are positively genetically correlated with both ASB
165 and COVID-19—having a noisy workplace, doing heavy manual labor, and having COPD—are also
166 strongly inversely genetically correlated with education years, verbal reasoning, and average income.

167 We observed positive r_{gs} between ASB and the psychiatric and violence-related traits we
168 measured. But none of these traits were genetically correlated with COVID-19. That they were not
169 comports with a meta-analytic review of mood disorders and risk for COVID-19 in 91 million
170 individuals¹⁷. Namely, Ceban *et al.* (2021) found no association between pre-existing mood disorders
171 and COVID-19¹⁷. Thus, the link between ASB and COVID-19 is unlikely to be due to those engaging
172 in ASB having comorbid mood disorders.

173 We note that the strength of the r_g for ASB and COVID-19 dropped from 0.51 (release 4) to
174 0.35 (release 6). Earlier GWA study releases by the COVID-19 Host Genetics Initiative capture data
175 from earlier timepoints in the pandemic—release 4 being earlier (October 20, 2020) than release 6
176 (June 15, 2021). This may be important since release 4 occurred before vaccines against SARS-CoV-2
177 were available, and by June 15, 2021, 47% of those eligible for vaccination had completed an initial
178 protocol for full vaccination in the U.S.¹⁸. Also, both releases 4 and 6 occurred prior to the appearance
179 of the more transmissible Omicron (B.1.1.529) variant, which most on the planet are expected to
180 encounter eventually^{19,20}. Thus, our results seem to reflect an increased risk of exposure to SARS-
181 CoV-2 early in the pandemic for those prone to ASB. If those with antisocial tendencies
182 disproportionately refuse vaccination against SARS-CoV-2, however, the impact of ASB over time
183 may have shifted from who gets exposed to SARS-CoV-2 to who gets severe disease.

184 Our study has limitations, which must also be considered. First is that the h_g^2 estimates for both
185 measures of COVID-19, while >0 , were very small. This indicates that, based on the GWA results,
186 SNPs can only explain a very small proportion of the individual differences in risk for COVID-19.

187 Hence, although the r_{gs} between ASB and COVID-19 were considerable, in absolute terms the genetic
188 variance that is overlapping between the two traits is low. Second is that r_{gs} , while robust against most
189 environmental confounders, can still suffer from genetic sources of confounding (i.e., even with r_{gs} , as
190 we mentioned above, correlation is not necessarily causation). To illustrate, it seems unintuitive and
191 unlikely that not being breastfed as a baby and eating less cheese cause ASB. One should, for
192 somewhat obvious reasons, be similarly cautioned against the conclusion that being breastfed as a baby
193 and eating more cheese protect against COVID-19, despite the apparent r_{gs} . Indeed, we chose these
194 dietary traits to communicate the point that the shared genetic architecture that these have with
195 education years, verbal reasoning, and average income seem the more plausibly causal phenomenon.
196 Third, supposing that some of the r_{gs} represent causal linkages in some way, we nonetheless cannot
197 determine the direction of causality with r_{gs} alone. For much of the discussion above, we tacitly
198 presumed plausible directions of effect (e.g., ASB causing exposure to SARS-CoV-2 and, thus,
199 COVID-19 versus COVID-19 causing ASB). But with all the traits in our matrix, the prevailing
200 direction of effect could be the opposite and/or some level of bi-directional causation may exist^{16,21–23}.
201 And, as alluded to by “shared genetic architecture,” the correlated traits could be tagging a latent
202 causal factor. These uncertainties are avenues for future research. Future studies could use either latent
203 causal variable (LCV)²² models to infer causality between traits or perform bi-directional MR, an
204 instrumental variables technique, for which both directions of effect are probed. Regarding MR, few
205 genome-wide significant signals have been found for ASB, and using SNPs weakly associated with
206 ASB as instrumental variables would violate the assumptions necessary to perform MR. But assuming
207 SNPs strongly associated with ASB are eventually found, bi-directional MR can be used to decipher
208 the prevailing directions of effect between ASB and traits with which it’s associated. A fourth
209 limitation is that our findings are limited to those of European ancestry. The limitations

210 notwithstanding, r_{gs} obtained from LDSC are not affected by sample overlap (i.e., participants being in
211 both GWA studies for which the r_{gs} were calculated)¹⁶. This is a strength of study, which enabled us to
212 capitalize on the power of large, population-based cohorts and publicly available GWA studies to
213 probe timely questions. Finally, working to understand the etiology of ASB gets us closer to thinking
214 about strategies to provide relief to a large part of the global population—both those engaged in ASB
215 and those devastated by it.

322 **Table 1.** GWA study data sources.

Trait (abbreviation)	Data source: Consortium and Availability	Effective Sample Size
Average total household income before tax (“average income”)	MRC-IEU; IEU Open GWAS Project identifier: ukb-b-7408; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	397,751
Education years	Okbay <i>et al.</i> (2016) ²⁷ ; Social Science Genetic Association Consortium (SSGAC); https://www.thessgac.org/ ²⁸	293,723
Healthspan	Zenin <i>et al.</i> (2019) ²⁹ ; (UKBB; n=300,447 European); https://www.gwasarchive.org/	300,447
Lifespan	Timmers <i>et al.</i> ³⁰ (2019); UKBB/LifeGen study; https://datashare.ed.ac.uk/handle/10283/3209	1,012,240
Word interpolation (“verbal reasoning”)	UKBB/Neale lab; IEU Open GWAS Project identifier: ukb-d-4957; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	98,753 cases and 18,062 controls
Breastfed as baby	MRC-IEU; IEU Open GWAS Project identifier: ukb-b-13423; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	251,150 cases and 100,944 controls
Cheese intake	MRC-IEU; IEU Open GWAS Project identifier: ukb-b-1489; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	451,486
Self-rated happiness (“happiness”)	UKBB/Neale lab; IEU Open GWAS Project identifier: ukb-a-367; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	110,935
Parkinson's disease	Nalls <i>et al.</i> (2019) ³¹ . International Parkinson's Disease Genomics Consortium; IEU Open GWAS Project identifier: ieu-b-7; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	33,674 cases and 449,046 controls
COVID-19	COVID-19 Host Genetics Initiative, release 4 ³² ; IEU Open GWAS Project identifier: ebi-a-GCST010780; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	14,134 COVID-19 cases and 1,284,876 controls (release 4) SNPs=12,500,447
COVID-19	COVID-19 Host Genetics Initiative, release 6 ³² https://www.covid19hg.org/results/r6/	112,612 COVID-19 cases and 2,474,079 controls (release 6) SNPs= 8,141,092
Job involves heavy manual or physical work (“heavy manual labor”)	MRC-IEU; IEU Open GWAS Project identifier: ukb-b-2002; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	263,615
Noisy workplace	MRC-IEU; IEU Open GWAS Project identifier: ukb-b-2091; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	151,624
ASB	Broad Antisocial Behavior Consortium (BroadABC); http://broadabc.ctglab.nl/ (data available upon request) ^{12,33}	56,575
Townsend Deprivation Index	MRC-IEU; IEU Open GWAS Project identifier: ukb-b-10011; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	462,464
Gastrointestinal diseases	FINNGen Biobank analysis; 39,639 cases and 56,860 controls (European); binary; IEU Open	39,639 cases and 56,860 controls

	GWAS Project identifier: finn-a-K11_GIDISEASES; https://www.finngen.fi/fi/ ²⁴⁻²⁶	
Chronic obstructive pulmonary disease (COPD) differential diagnosis	UKBB/Neale lab; IEU Open GWAS Project identifier: ukb-d-COPD_EXCL; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	26,710 cases and 334,484 controls
Genitourinary diseases	UKBB/Neale lab; IEU Open GWAS Project identifier: ukb-d-XIV_GENITOURINARY; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	71,620 cases and 289,574 controls
Neuroticism score (“neuroticism”)	MRC-IEU; IEU Open GWAS Project identifier: ukb-b-4630; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	374,323
Seen doctor for nerves, anxiety, tension, or depression	MRC-IEU; IEU Open GWAS Project identifier: ukb-b-6991; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	158,565 cases and 300,995 controls
Plays computer games	MRC-IEU; IEU Open GWAS Project identifier: ukb-b-4779; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	462,433
Victim of physically violent crime (“violent-crime victim”)	UKBB/Neale lab; IEU Open GWAS Project identifier: ukb-d-20529; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	21,926 cases and 95,920 controls
Risk tolerance (self-rated: “Would you describe yourself as someone who takes risks?”)	Karlsson Linnér et al. (2019) ²⁸ ; Social Science Genetic Association Consortium (SSGAC); https://www.thessgac.org/	466,571
Witnessed sudden violent death (“saw sudden violent death”)	UKBB/Neale lab; IEU Open GWAS Project identifier: ukb-d-20530; https://gwas.mrcieu.ac.uk/datasets/ ²⁴⁻²⁶	15,959 cases and 101,903 controls

323 UKBB = UK Biobank; IEU = Medical Research Council Integrative Epidemiology Unit at the
324 University of Bristol; GWAS = genome-wide association study. Most of the GWA studies were
325 performed solely in those of European ancestry. The two COVID-19 GWA studies came from meta-
326 analyses that predominately consisted of those of European ancestry, but the COVID-19 (release 6)
327 included some participants of other ancestral backgrounds. However, the COVID-19 Host Genetics
328 Initiative cohort that generated the COVID-19 data performed sensitivity analyses generating SNP-
329 heritability (h_g^2) estimates for COVID-19 using only the data for those of European ancestry for release
330 6 and compared these to the h_g^2 estimates for the meta-analytic measures we used: the h_g^2 estimates
331 were nearly the same (see the Supplementary table 6 that accompanies the COVID-19 Host Genetics
332 Initiative paper³²). Were the h_g^2 estimates substantially different, use of the meta-analytic data for
333 LDSC would have been inappropriate. Thus, though we did not have access to the European-only

334 ancestry data for COVID-19 (release 6), the h_g^2 estimates for the meta-analytic data do not appear to be
335 confounded by mixed ancestries.
