24
25 **Summary**

26 The COVID-19 Exposure Assessment Tool (CEAT) allows users to compare respiratory
27 relative risk to SARS-CoV-2 for various scenarios, providing understanding of how
28 combinations of protective measures affect exposure, dose, and risk. CEAT incorporates
29 mechanistic, stochastic and epidemiological factors including the: 1) emission rate of virus, 2)
30 viral aerosol degradation and removal, 3) duration of activity/exposure, 4) inhalation rates, 5)
31 ventilation rates (indoors/outdoors), 6) volume of indoor space, 7) filtration, 8) mask use and
32 effectiveness, 9) distance between people, 10) group size, 11) current infection rates by variant,
33 12) prevalence of infection and immunity in the community, 13) vaccination rates of the

34 NOTE: This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice.
community, and 14) implementation of COVID-19 testing procedures. Demonstration of

35 CEAT, from published studies of COVID-19 transmission events, shows the model accurately
36 predicts transmission. We also show how health and safety professionals at NASA Ames
37 Research Center used CEAT to manage potential risks posed by SARS-CoV-2 exposures.

43 **Introduction**

44 The novel severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) that causes the
45 coronavirus disease 2019 (COVID-19) has quickly spread around the world and was formally
46 recognized as a pandemic by the World Health Organization (WHO) on March 11, 2020
47 (WHO, 2021 March 11). COVID-19 poses a great public health, clinical, economical, and
48 societal burden worldwide. SARS-CoV-2 transmission occurs mainly through close contact
49 (WHO, 2021 March 11), by direct and indirect contact (via fomites), and through the air via
50 respiratory droplets and/or airborne particles (i.e. aerosols) (Jayaweera et al. 2020).

51 The global and local transmission dynamics drove an urgent need for assessing potential
52 risk of transmission while performing different activities in various facilities. Public health
53 officials have had to reevaluate how the public should interact to reduce and contain viral
54 spread (Bargain and Aminjonov 2020; Keskinocak et al. 2020; Deckert et al. 2021; Heydari et
55 al. 2021), leading to assessment of worker and group risks associated with viral exposure in
56 various settings (Din et al. 2020; Mutambudzi et al. 2020; Sun et al. 2020; Wells et al. 2021).
57 Risk assessment and planning regularly consider the contribution of an array of factors, using
58 largely qualitative guidance from public health and media sources (Feyman et al. 2020;
59 Keskinocak et al. 2020; Wells et al. 2021), such as the viral exposure pathways, risk of infection
60 (e.g. number of cases per population), efficacy of interventions and personal protective
61 equipment (PPE; e.g. masks, gloves), human behavior (e.g. adhering to public health
62 guidelines, hand washing, social distancing), and environmental factors (e.g. ventilation).
63 Given the numerous factors that affect exposure to the virus, qualitative assessments are
64 insufficient when trying to compare various courses of action or potential mitigation options.

65 The WHO and the Centers for Disease Control and Prevention (CDC) have released
66 guidance for risk assessment and management of exposure in the context of COVID-19 at work
67 (CDC, 2021 August 24), towards health-care personnel (CDC, 2021 September 10),

68 community-related (CDC, 2021 March 1 2022), and associated with domestic and international
69 travel (CDC, 2021 July 2). However, the qualitative nature of these guidelines makes it difficult
70 to quantify the exposure risk in varied settings.

71 Researchers have developed tools that predict the risk of transmission from exposure
72 through inhalation of emitted SARS-CoV-2-containing aerosols. Risk assessment tools provide
73 an important means of gaining understanding of dynamics of transmission and evaluating and
74 comparing risks associated with local environmental conditions, community epidemiological
75 factors, and mitigation options. Typically, the infectious disease risk assessment tools utilize
76 either a deterministic dose-response approach or, alternatively, a Wells-Riley approach (Sze
77 To and Chao 2010). A detailed comparison of dose-response models and Wells-Riley models
78 applied to infectious disease risk assessment is provided in Sze and Chao, 2010, addressing
79 both models' advantages and limitations. Specific to SARS-CoV-2, Miller et al. (2021) (Miller
80 et al. 2021) offers a Wells-Riley-based method to model transmission and has developed a
81 companion COVID-19 Aerosol Transmission Estimator spreadsheet-based tool (CIRES 2020).
82 The Wells-Riley-based method addresses physical factors that contribute to indoor
83 transmission, applying a uniform well-mixed box (WMB) assumption and transmission
84 estimates using the Wells-Riley equation. Bazant and Bush, 2021 (Bazant and Bush 2021)
85 provide a comprehensive physical model of the factors that affect indoor transmission and
86 released a spreadsheet-based tool and online app (Khan et al. 2021) that calculates safety
87 guidelines to limit the viral transmission based upon Wells-Riley and WMB assumptions. This
88 tool recommends the total number of hours of exposure that are permissible given the number
89 of people, their behavior, characteristics of the room and its ventilation, and the prevalence of
90 COVID-19 and variants in the community. Parhizkar, et al., 2021 (Parhizkar et al. 2021)
91 developed a dose-response approach and model that uses a WMB assumption and a novel
92 treatment of the inhaled and deposited doses. They demonstrate the model's capability against
93 well-documented COVID-19 outbreaks and offer a demo version of an online tool (Safe Air
94 Spaces 2022). Wagner, et al., 2021 (Wagner et al. 2021) offer a comprehensive modeling study
95 that examines both indoor and outdoor exposures from two-person interactions, examining near
96 field and far field effects, and modeling the behavior of particulates of various sizes. Other
97 modeling efforts have focused on predicting transmission risks using epidemiological and
98 behavioral factors and population statistics (Chande, Lee, et al. 2020; Chande, Gussler, et al.
99 2020; Harvard IQSS 2020), without addressing facility- and event-specific physical
100 mechanisms that would affect transmission risk.

101 Rigorous study of the physics of aerosol behavior in indoor spaces have also been
102 accomplished using both experiments and computational fluid dynamic (CFD) numerical
103 simulations. These studies analyzed key aspects of the hydrodynamics produced by expiratory
104 events, including sneezing, coughing, talking, singing and breathing, and the dispersion
105 processes of the resulting aerosol cloud (Fabregat, Gisbert, Vernet, Dutta, et al. 2021; Fabregat,
106 Gisbert, Vernet, Ferré, et al. 2021; Li et al. 2022). While these experiments and modeling
107 studies produce important understanding of the aerosol behavior in the environment and the
108 respiratory system, their results are specific to the defined scenarios that were modeled and are
109 too computationally intensive to be used directly and routinely by non-experts.

110 Our goal was to develop a simple-to-use, quantitative exposure and risk assessment tool
111 that addresses the factors summarized **Fig. 1** and was based on principles of epidemiological,
112 physics and engineering to provide benefit to risk assessors and decision makers in a variety
113 of settings. Additionally, we wanted to incorporate recent findings regarding disease
114 characteristics and virus dynamics Our focus was to create a tool that could be easily used by
115 people who are tasked with making recommendations or decisions for their organizations or
116 groups (e.g., businesses, schools, and civic groups) on approaches to reduce viral exposure.
117 The end result of our project has been the development of the COVID-19 Exposure Assessment
118 Tool (CEAT). The CEAT model is embedded in an Adobe® PDF (Portable Document Format)
119 file and was coded in JavaScript using Adobe Acrobat's ® "Prepare a Form" function. The
120 model's user interface is shown in **Fig. 2A** and is available for download at [https://www.cov-](https://www.cov-irt.org/exposure-assessment-tool/)
121 [irt.org/exposure-assessment-tool/](https://www.cov-irt.org/exposure-assessment-tool/) as a PDF. The PDF platform was chosen instead of a web
122 app, since the PDF allows organizations to use the tool within the privacy and security of their
123 own networks and devices, eliminating any concern that an organization's private worker
124 safety information was being shared externally. Additionally, the PDF offers the ability to save
125 and disseminate the results for specific events and scenarios as individual PDF files. The
126 underlying algorithm used in CEAT leverages aspects of both Wells-Riley models and dose-
127 response models. An important difference between the CEAT model and the other models
128 discussed above is that CEAT assesses the additional higher concentration of virus containing
129 aerosols that may occur when people are in close proximity and applies this approach to groups
130 between 2 and 250 people, both indoor and outdoors. The model relies on information that the
131 users would have available or could reasonably estimate, addresses the mechanisms that are
132 within the organization's control (i.e, distancing, duration, ventilation rates, filtration, mask
133 wearing, vaccination requirements, and option for indoor/outdoor activities), and
134 communicates a clear and easily interpretable result. The model attempts to address the full

135 range of exposure risks within a community, from highest exposure risk to people known to be
136 infected, typical of a clinical environment, to lowest-risk exposure to people who rigorously
137 follow public health guidance.

138 **Results**

139 **Model Overview**

140 CEAT allows users to estimate group-wide and individual relative dose, an individual
141 dose, and transmission risk from potential SARS-CoV-2 exposure in various scenarios, based
142 on the key mechanistic, viral, and epidemiological factors summarized in **Fig. S1A** and **Table**
143 **1**. Here we present 1) a brief overview of the CEAT model; 2) the demonstration of the model
144 applied to real-world, well-documented transmission scenarios; 3) describe how CEAT was
145 applied operationally by NASA Ames Research Center's Health and Safety office to manage
146 exposure risk of its staff. Full details of the mathematical model used for CEAT can be found
147 in the **STARS Methods** section.

148 Exposure is defined as the contact of an agent with an external boundary of a receptor
149 (exposure surface) for a specific duration (US EPA 2019). Dose is the amount of material that
150 passes through the boundary based upon the intake rate, concentration and exposure time. In
151 this case, the boundary is the entrance to the respiratory system (i.e., through the nose, mouth,
152 and other mucosa) (US EPA 2019) and the intake rate is the inhalation rate. Importantly, rather
153 than a mass of material, we are only concerned with the quantity of material that contributes to
154 transmission of disease. For viral dose-response models, the disease causing quantity is often
155 expressed in plaque forming units (PFU). A Wells-Riley based model expresses dose as an
156 amount of quanta and when applied in a Poisson probability distribution, the complement of
157 the Poisson distribution's probability mass function (with the assumption number of
158 occurrences is zero) can be used to predict an infection rate (Riley et al. 1978, (Sze To and
159 Chao 2010), (Rudnick and Milton 2003). Engaging in activities with high inhalation and
160 exhalation rates, such as group exercise, strenuous work tasks or singing (Hamner 2020), is
161 thought to correlate with higher doses and transmission risks (Jang et al. 2020). Dose is the
162 appropriate endpoint for a risk model, since it captures the contributions of concentration,
163 exposure time, and inhalation rate. Since the model is meant to evaluate risks for events that
164 includes groups of people and the number of people in group is a variable that can be adjusted
165 when planning events, we use a total group dose ($D_{Group\ Dose}$) as the basis for our model:

$$166 \quad D_{Group\ Dose} = \underline{C} \times \underline{Q}_{Inhalation} \times \Delta t \times Pe_{Total} \text{ (Eq 1)}$$

167 where $Q_{Inhalation}$ is the average inhalation rate for the group, \underline{C} is the average concentration
168 of the agent (in this case, aerosols containing SARS-CoV-2), Δt is the duration of group
169 exposure, and Pe_{Total} is the number of people exposed in the group, which we will assume are
170 all of the people in the group. The $D_{Group Dose}$ represents the total quantity of infectious
171 material that enters the respiratory tracts of all of the group by inhalation over the duration of
172 the potential event.

173 Rather than using an explicit calculation of group dose, the CEAT model takes the form of
174 a relative dose model, comparing a specific evaluated scenario to a defined high risk baseline
175 by a ratio:

$$176 \quad \text{Ratio of Doses} = \frac{D_{Evaluated Group Dose}}{D_{Baseline Group Dose}} \quad (\text{Eq 2})$$

177 When the specific scenario results in a value that is equal to the baseline scenario, the ratio is
178 1. The ratio may be orders of magnitude greater or less than 1 depending on the specific
179 evaluated scenario. By benchmarking the dose calculations to a baseline scenario that is
180 considered high risk by Occupational Safety and Health Administration (OSHA), the model's
181 results can be aligned with the OSHA classifications of exposure risks (US OSHA 2020) (see
182 **Table S1**). The OSHA risk classifications depend on the industry type, the need for close
183 contact (i.e. within 6 feet or approximately 2 meters) with people known to be or suspected of
184 being infected with SARS-CoV-2, or requirement for repeated or extended contact with
185 persons known to be or suspected of being infected with SARS-CoV-2 (US OSHA 2020). We
186 define the baseline scenario to represent a person (perhaps a healthcare worker) who is exposed
187 to a COVID-19 infected person for 15 minutes in an indoor setting with typical ventilation. We
188 apply a range of assumptions to this scenario, addressing each of the factors in **Table S2** to
189 arrive at a baseline scenario. This scenario was estimated to be consistent with between 4 and
190 9 percent likelihood of infection, based upon the range of infection rates reported in various
191 studies due to close contacts, presumably involving wild type SARS-CoV-2 transmission based
192 upon the dates of the cases included in the studies in early 2020 (Ng et al. 2021; Qian et al.
193 2021). The inhalation dose values for other scenarios are compared to the baseline value
194 through the simple ratio.

195 A critical variable that must be estimated by the model is the concentration of virus-
196 containing aerosols that occurs as a result of the exhalation from people in the group at the
197 event. The underlying concentration model used in CEAT assesses both the contributions of
198 concentration due to the proximity of people (i.e., people in the "near field" whether indoors

199 or outdoors) and the build up of concentration in a room over time (i.e., “far field”) after Nicas,
200 2009 (Nicas 2009a). As presented in the **STARS Methods**, to determine the near field
201 concentration, we employ a method that captures the effect of turbulent mixing that occurs due
202 to higher air changes through ventilation or increased mixing of the air (e.g., through the HVAC
203 system recirculating the air). Specifically, we employ equations that use the air change rate and
204 total volume for an indoor space to calculate an eddy diffusivity based on relationships
205 previously proposed (Cheng et al. 2011; Foat et al. 2020; Venkatram and Weil 2021). We apply
206 the calculated eddy diffusivity in a novel way that still allows us the advantage of using the
207 computationally-simple near- and far-field approach. Outdoors, only the near field
208 concentration contributions are used, since the far field is considered to be negligible (Nicas
209 2014). Furthermore, also presented in detail in the **STARS Methods**, the CEAT concentration
210 algorithm uses an approach for extending the near- and far-field approach to groups of people
211 at set distancing intervals through the application of the superposition principle (Illingworth
212 1991). The superposition principle has been applied in the modeling of outdoor air pollutants
213 from multiple sources (Stockie 2011) and to indoor air quality modeling of gaseous pollutants
214 (Cheng et al. 2011).

215 An important driver of the dose calculation is a stochastic approach that estimates the
216 expected value of the number of infections in the group, since this is correlated to the quantity
217 of virus-containing aerosols emitted in the modeled scenarios. In the baseline scenario, we
218 assumed there to be one infected person. For the evaluated scenario, the number of infections
219 in the group is dependent on the user's estimate of the group's behavior characteristics and an
220 estimate of the number of active cases in the community population, calculated using the
221 prevalence of diagnosed COVID-19 in the community, an estimate of the duration of
222 infectiousness, and an estimate of the fraction of cases thought to be undiagnosed. The resulting
223 number of active infections may be less than or greater than 1.

224 We adjust the calculated dose ratio result by additional factors: 1) concentration of virus-
225 containing aerosols that occurs as a result of the exhalation from people in close proximity, 2)
226 number of infections in the group, 3) current community prevalence of variants, 4) relative
227 infectiousness of the prevalent variants; 5) current prevalence of immunity in the community
228 of group gained by recovery or vaccination, 6) efficacy of immunity in preventing transmission,
229 and 7) efficacy of surveillance testing of the group. The full CEAT dose ratio equation (**Eq. 3**)
230 is shown in **Fig. 1B**, along with a mapping of where each of the CEAT step's inputs are applied
231 in the equation. The expanded version of the CEAT dose ratio equation, showing the NF and
232 FF terms is found in Equation S46.

233 Users can use the tool to assess two side-by-side scenarios, and results are shown for the
234 worst case individual dose ratio, total group dose ratio, and near- and far-field contributions to
235 the total group dose ratio. In the CEAT tool user interface, we refer to this dose as an
236 “exposure” rather than a “dose,” since exposure is a more recognized term and will not be
237 misconstrued by a user to have any association with a vaccine dose or medication dose. The
238 group dose ratios for both scenarios are then categorized into four exposure risk bins, ranging
239 from “Lower Exposure” through “Very High Exposure” and presented graphically (**Fig. 1A**).
240 The model’s results include:

- 241 ● **Group-wide Exposure (Dose) Ratio (Fig. 1B, Eq. 3):** Ratio of the group-wide dose
242 to the baseline group-wide dose. This result is also shown in the bar graph. This result
243 takes into account the dose that group members are exposed to, as well as the size of
244 the group. Accordingly, this group-wise result provides an evaluation of the overall
245 risk of the event.
- 246 ● **Far-Field Group-wide Exposure (Dose) Ratio:** Portion of the group-wide dose that
247 is due to the well-mixed concentration in the room.
- 248 ● **Near-Field Group-wide Exposure (Dose) Ratio:** Portion of the group-wide dose that
249 is due to the localized concentration in the room due to the proximity of people.
- 250 ● **Individual Exposure (Dose) Ratio (Fig. 1B, Eq. 4):** This is the ratio of the individual-
251 dose to the baseline individual dose.
- 252 ● **Individual Dose (Fig. 1B, Eq. 5):** An estimate of the highest-exposed person’s dose in
253 units of quanta.
- 254 ● **Infection Rate (%):** To determine the infection rate, the Individual Dose is applied to
255 a Poisson distribution to calculate the probability that the exposed group will become
256 infected. The estimated rate of infection within the group can be inferred from this
257 probability. The relationship between the dose and the infection rate can be adjusted
258 through using a variable in the model called the “Poisson Distribution Adjustment
259 Factor” in Step 10, which provides a linear adjustment factor to that relationship. The
260 dose is multiplied by 1 over the adjustment factor.
- 261 ● **# of Index Infectors:** Provides the assumed number of the infected individuals that
262 were present based upon the selections and inputs in Step 1, Step 2, and Step 10 in the
263 model. The model used this value to estimate the initial source(s) of infection in the
264 room or at the event. This value can be a less than one person or fraction of a person,
265 since it represents a probabilistically-determined number of people
266

267 **Demonstration of the Model Applied to Documented Transmission Events**

268 We have demonstrated the effectiveness of CEAT results to predict infection rates for
269 known transmission events by assembling data from eleven transmission events that were
270 documented in the literature (listed in **Table 2**). All of the events except for one, occurred
271 before the vaccines were available and before the emergence of SAR-CoV-2 variants. To
272 evaluate each of these scenarios in CEAT, we collected the data needed for each step and set
273 the average daily cases per 100,000, such that the “Number of people initially infected” in the
274 results would be equal to one, assuming there was one index case in each scenario. There are
275 two ways of conceptualizing how the CEAT model is addressing this scenario of a known
276 infected person (or index case), which are both mathematically equivalent:

- 277 1. A receptor at the center and all others are potential sources. The emissions may occur
278 from any one of the sources. We calculate an expected value of the dose for the person
279 at the center, assuming that all of the people are equally likely to be the emitter, with a
280 probability of φ , where $\varphi = 1/(\text{Number of People}-1)$ and the one emitter has a quanta
281 based emission rate of \dot{M} . CEAT sums the results from all people (both FF and NF), s
282 and multiplies by φ . This is the expected value of dose that the person located at the
283 center of the group would receive if there was one emitter in the room, given that the
284 emitter could have been anywhere in the room.
- 285 2. The source is at the center and all of the people are receptors. We calculate the expected
286 value of the dose for each receptor (i.e., each susceptible person) given an emitter at the
287 center, emitting at \dot{M} . CEAT sums the results from all people (both FF and NF) and
288 then divides by the number of receptors (i.e., number of people - 1) to arrive at an
289 average. The result is the expected value of the mean dose that all people would receive
290 in the room from the one emitter.

291 When examining CEAT performance for transmission events, we use the event’s number
292 of infections, and the infection rate, P , which is the number of secondary cases (total infected)
293 divided by the total susceptible people, yielding, $P = \frac{\text{Total Infected}}{\text{Total Susceptible}}$. The total
294 number of total susceptible is equal to the total people minus the index cases (typically equal
295 to one). Using the information describing the event’s duration, room size, ventilation rate,
296 activity type and any information on the location or the spacing of the people (**Table 2**), the
297 CEAT individual dose is calculated. The infection rate can be predicted using the same
298 statistical approaches that are used in the Wells-Riley model (Riley et al. 1978), in which the

299 probability of at least one infection is computed using an assumed Poisson distribution, with
300 shape parameter equal to $D_{CEAT i}$, as shown in **Eq. 7**:

$$301 \quad P_{CEAT Prediction} = 1 - \exp(-D_{CEAT i}) \quad (\text{Eq 7})$$

302 The CEAT predicted infection rate is plotted against the observed cases among the
303 susceptible people (**Fig. 2A**). Information on vaccination, variant, and mask usage (which was
304 none) was gathered from the reported events (**Table 2**). The CEAT results show a high
305 correlation with the observed with an almost 1-to-1 (i.e. $R^2 = 0.94$) relationship to the observed
306 infection rates (**Fig. 2A**). In addition, CEAT correctly binned the events as high risk and there
307 is a significant positive correlation between the number of observed infections and CEAT
308 group-wise dose ratio (**Fig. 2E**). As discussed in the previous section, to assess infection rate,
309 the initial relationship between the dose and the infection rate is unadjusted and then through
310 the “Poisson Distribution Adjustment Factor” in step 10 we achieve the corrected adjustment.
311 With CEAT, even before this adjustment takes place, we still observe a strong correlation to
312 the observed infection rates (**Fig. 2B**).

313 As a comparison to the CEAT results, the traditional Wells-Riley result that assumes a well-
314 mixed dose, \underline{D}_{WMB} , is calculated using:

$$315 \quad P_{Wells Riley Prediction} = 1 - \exp(-D_{WMB}) \quad (\text{Eq 8})$$

316 Using the same assumptions applied to the CEAT model for each of the events, including the
317 same quanta based emission rate, the Wells-Riley predicted infection rates for both the adjusted
318 (**Fig. 2C**) and unadjusted (**Fig. 2D**), clearly show poor predictions when compared to the
319 observed infection rates. The CEAT approach clearly outperforms the Wells-Riley in
320 predicting infection rate in these cases (**Fig. 2E**). Interestingly, we also observe that the CEAT
321 outperforms the Wells-Riley model with several other important parameters which include:
322 distancing, density, breathing rate, and volume of the room (**Fig. 2E**).

323 **CEAT use to determine risk assessment for social gatherings**

324 To demonstrate how CEAT can estimate potential exposure risk to COVID-19 for
325 gatherings and events, we used CEAT to assess a set of hypothetical gathering scenarios that
326 could have occurred in three locations in the United States (**Fig. 3**) using published CDC county-
327 level COVID-19 7-day average new case data for the locations on 31 January 2022 (CDC
328 2020a). We chose three representative locations: 1) a county with a low vaccination rate and

329 high 7-day average new case rate (Knox County, TN), 2) a county with a moderate vaccination
330 rate and a 7-day average case equivalent to the national average (Suffolk County, MA), 3) a
331 county with the high vaccination rate and a low daily cases (Montgomery Country, MD). At
332 the time of analysis for all counties the Omicron variant accounted for >99% of COVID-19
333 cases (CDC 2022). We assumed the gatherings lasted 5 hours and would be held both indoors
334 or outdoors. We also included a range of scenarios for distancing, type of masks being used,
335 composition for the group of people, and location (i.e. indoors or outdoors). Lastly, we included
336 analysis for 3 different group characteristic scenarios for the gatherings: 1) the general public
337 (i.e. “equal to the community average”); 2) groups of people that are 100% vaccinated and
338 follow all public guidelines; and 3) groups of people that are 100% vaccinated, follow all public
339 guidelines, and testing was required before the gathering.

340 The exposure assessment from this analysis can help guide individuals to safely plan
341 gatherings and events. As expected in all scenarios, if the gathering is composed of 100%
342 vaccinated individuals that were tested and follow all public guidelines, the exposure risk is
343 very low both indoors and outdoors with the best masks and with an increasing number of
344 people it increases to medium risk (**Fig. 3**). When considering the gathering in a general public
345 scenario (e.g. eating at a restaurant), for all indoor scenarios in all counties without a mask with
346 >10 people in the room, the group is at high risk of exposure to SARS-CoV-2 even when spaced
347 3 meters (approximately 10 feet) apart. Overall we demonstrate with CEAT the more
348 precautions followed, the greater the reduction of exposure and this scenario can be used as a
349 guide for the public on how to use CEAT to properly determine the safest way to assemble
350 while keeping the risk of exposure to COVID-19 low.

351

352 **NASA Ames Research Center used CEAT to determine the safest method for** 353 **allowing workers to return to work**

354 CEAT has been used by the NASA Ames Research Center (ARC) safety office to assist
355 them in planning for workers to return to their campus. Starting on December 11, 2020, NASA
356 ARC began to use the first beta version of CEAT to assess whether the tool could assist in
357 gaining understanding on how to keep essential workers safe when having to work in person
358 on the NASA ARC campus. To demonstrate how NASA ARC safety office has utilized this
359 tool, we provide their assessment of exposure potential in 73 different scenarios throughout the
360 campus (**Fig. 4** and **Table S3**). Since NASA ARC has been using this tool throughout the
361 pandemic, every assessment used the latest COVID-19 case numbers from the State of

362 California (US State of California 2022a). As is shown in **Fig 4**, the case numbers will vary
363 due to the changing number of cases for that particular date of assessment, so it is essential to
364 analyze the risk continuously with the most up-to-date COVID-19 case rates.

365 For each scenario, CEAT was used to determine the maximum number of personnel that
366 could be allowed to be in each location such that the exposure risk was the lowest, while still
367 allowing the work to be performed (**Fig. 4** and **Table S3**), which during pre-pandemic would
368 have been occupied by more personnel. These maximum occupancy were included in the
369 project's Return To Onsite Work (RTOW) plan that was reviewed by the safety office. In
370 general, most operations could occur with one to two people thus reducing the potential
371 exposure and resulting in a lower exposure risk. However, some operations required up to 10
372 personnel to be fully functional. As expected, these conditions increased the COVID-19
373 exposure risk to medium level. NASA ARC considered the group of people at work to be
374 composed of people following all public health guidance which had the effect of reducing the
375 assumed probability of COVID-19 prevalence in the group below the average for the
376 community, with exception of a few locations where employees from organizations outside
377 NASA ARC would participate. Social distancing was assumed to be the maximum possible for
378 that work to be performed. For some locations such as "Critical activities when spacecraft
379 arrives and extra hands needed - Location C" social distancing could not be achieved while
380 performing the work, so other factors were considered, such as limiting the project duration, to
381 find the lowest risk exposure estimate possible for that location and operation.

382 The breathing rate and vocalization for each location were also part of the decision in
383 determining the maximum number of people in each location. Of all the locations and
384 operations analyzed, only one location/operation resulted in the worst case scenario which
385 produced the highest risk exposure assessment (i.e. "High-Medium Risk Exposure"). The
386 operation "Material testing such as compression testing and fatigue testing" typically involved
387 high exertion physical activities as well as heavy exertion for the breathing rate and speaking
388 over a long duration. The majority of the other locations and operations only require passive
389 breathing rate and standing/speaking. The various operations that required elevated breathing
390 rate and vocalization to light exertion typically had shorter project durations in order to reduce
391 the COVID-19 exposure risk.

392 To provide inputs for the Air Changes per Hour (ACH), the ventilation rates for each
393 location were either provided by the building managers, were directly measured, or were
394 assumed using the guidelines in Step 8 in the CEAT. The most accurate ventilation rates
395 available to the safety office were used in the model for each scenario. With the available data

396 and estimated parameters in some cases, CEAT allowed NASA ARC to determine the
397 operation-specific mitigation approaches, allowing its essential workers to return to work in-
398 person with the low exposure risk to COVID-19.

399 CEAT has also been effective in allocating project resources and PPE where they would be
400 most beneficial. When reviewing RTOW plans, NASA ARC safety office used the CEAT as a
401 resource to recommend whether limited KN95/N95 masks would be effective at reducing
402 potential exposure risk. Similarly, projects used CEAT when purchasing portable air cleaners
403 (PACs), calculating the number of ACH needed to reduce risk to acceptable levels, typically
404 “Lower Exposure”. Multiple projects found the number of PACs needed to reduce risk to
405 acceptable levels were not financially feasible, and other controls such as increasing mask
406 effectiveness and/or working in a different location were more cost effective for the same risk
407 reduction. This allowed projects to spend their budgets more efficiently.

408 When the workplace face mask policy became optional for vaccinated personnel, CEAT
409 was used to identify potential locations and operations where face masks would be required
410 regardless of vaccination status. Locations and/or operations where the relative exposure risk
411 was in the “Medium” or “High” category were required to wear face coverings regardless of
412 vaccination status. CEAT was especially effective in this regard as it allowed the safety office
413 to provide this guidance using a consistent and unbiased method.

414 When tracking the CEAT model results over time, one can examine how the model
415 responds to changes in community conditions and changes in organizational policies. NASA
416 ARC tracked their worksite-specific relative group-wide exposure ratios with the California
417 seven-day case rate (**Fig. 5**). There was a strong correlation (correlation coefficient=0.9759)
418 between the two results, as would be expected, since the seven-day case rate is an input into
419 the CEAT model in Step 10 (**Fig. 1B, Eq. 3**). Specifically, NASA ARC used the location- and
420 operation-specific exposure risk ratios that were assessed on a biweekly basis to calculate a
421 “Centerwide Accepted Median Exposure Risk Ratio”. The fact that the CEAT results moved
422 up and down with the community conditions allowed the NASA ARC safety office to adjust
423 its guidance and mitigation strategies accordingly.

424 Beginning May 14, 2021, NASA ARC implemented the updated CEAT that included
425 variant prevalence. It was noted that the correlation between the “Centerwide Accepted Median
426 Exposure Risk Ratio” and the California case rate immediately decreased. However, at the
427 same time this updated CEAT iteration was implemented, the NASA ARC face mask policy
428 became optional for vaccinated personnel. Once NASA ARC reinstated their face mask policy
429 for all individuals regardless of vaccination status, the correlation between “Centerwide

430 Accepted Median Exposure Risk Ratio” and the California case rate appeared to return to
431 similar values before May 14, 2021.

432 **Discussion**

433 By establishing a set of equations that included mechanistic factors affecting nearfield and
434 far field concentration, filtration, group behavior, and SARS-CoV-2 infection and immunity
435 prevalence in the community, we developed a flexible, simple-to-use COVID-19 Exposure
436 Assessment Tool. The tool achieved our goal of allowing businesses, schools, government
437 agencies, and individuals to assess COVID-19 exposure to the risk for groups and
438 organizations. The tool is easy to use, computationally fast, and built on a well-developed and
439 documented mathematical model that includes aerosol behavior, knowledge of SARS-CoV-2
440 transmission dynamics, as well as the effect of proximity. Here, though our comparison of
441 CEAT results against observed transmissions for documented events, we demonstrate that
442 CEAT can provide the accurate predictions compared to known cases with observed infection
443 rates (**Fig. 2**), an example of how CEAT can be used for gatherings (**Fig. 3**), and real-time
444 usage of this tool demonstrating how NASA ARC safety office has been over the past year
445 (since the tool’s original release in December 2020) evaluating how to allow essential
446 employees to work in person with the lowest possible risk to COVID-19 exposure (**Fig. 4**).

447 As the CDC notes, the inhalation of fine respiratory droplets and aerosol particles is the
448 principal means of SARS-CoV-2 transmission (CDC 2020b). This is in line with recent
449 publications that have shown that SARS-CoV-2 is spread by airborne transmission through the
450 aerosols produced from breathing, talking, and singing (Chen et al. 2021; Miller et al. 2021;
451 Adenaiye et al.; Coleman et al.). Given this, the CEAT’s mathematical model addresses the
452 aerosol dynamics and transport, treating the suspended aerosols as if they are dispersed as
453 gasses would be using an eddy diffusivity approach, but also addressing deposition as a sink,
454 using the same approach for aerosol deposition that was presented in the COVID-19 Aerosol
455 Transmission Estimator spreadsheet-based tool (CIRES 2020), where an aerosol deposition
456 factor of 0.24 hr^{-1} was used.

457 To demonstrate the model, we examined eleven literature-documented events with one of
458 the events occurring in 11/2021 with known the Omicron variant and vaccine data (NIPH 2021)
459 (**Fig. 2** and **Table 2**). When comparing CEAT results to the Wells-Riley model, CEAT better
460 predicted the infection rate compared to the observed infection rates reported (**Fig. 2**). In
461 addition, the exposure scores for all events predicted a high risk of exposures, which correlates
462 to what was reported for each of these cases.

463 Schools and universities that have opened to in-person classes have been able to maintain
464 low to no COVID-19 cases by applying many of the mitigation methods that are included in
465 the CEAT, albeit independent of CEAT. The scenarios included in our assessment of gatherings
466 (**Fig. 3**) can be applied to such environments and seems to match the observations that are being
467 reported by schools and universities. Known outbreaks or superspreader events related to
468 school openings have been chiefly reported occurring outside the classroom environment,
469 including events during spring breaks (Doyle et al. 2021) or athletic-related events (Teran et
470 al. 2020), where enforcement of specific guidelines to reduce spread were not implemented.
471 Other COVID-19 models for school re-openings have also shown similar recommendations as
472 CEAT (Brooks-Pollock et al. 2021; Hernández-Hernández and Huerta-Quintanilla 2021;
473 Phillips et al. 2021). Brooks-Pollock et al. (Brooks-Pollock et al. 2021) provided a stochastic
474 transmission model based on social contact data and patterns of student mixing to determine
475 the impact and risk of COVID-19 transmission for universities in the United Kingdom. Since
476 their model only targets social patterns and behavior of students contributing to COVID-19
477 infections, the focus for their mitigation strategies was with reducing the number of students in
478 in-person classroom settings (i.e. increase social distancing), reducing living circles for
479 students, and included regular testing. Although their model only takes into account one
480 parameter from our model, the social distancing measures are in agreement with the exposure
481 risk assessment results from our CEAT analysis. There also have been two independent agent-
482 based models developed to assess SARS-CoV-2 transmission (Phillips et al. 2021) and
483 COVID-19 cases (Hernández-Hernández and Huerta-Quintanilla 2021). Similar to the model
484 described above, Phillips et al. (Phillips et al. 2021) agent-based model focuses on SARS-CoV-
485 2 transmission based on children's household sizes in the Ontario child care centers and school
486 buildings. They have also included parameters to take into account classroom sizes, sibling
487 influence, symptomatic and asymptomatic rates, and physical distancing. Hernández-
488 Hernández et al. (Hernández-Hernández and Huerta-Quintanilla 2021) presented an agent-
489 based model that utilizes the students' community network to predict spread of COVID-19
490 within a school setting. They also considered the following parameters: 1) status of COVID-
491 19; 2) physical distancing; 3) viral load; 4) hygiene standards; 5) confined spaces; and 6) social
492 interactions. As expected, both models demonstrated the importance of social distancing and
493 following the proper guidelines to prevent spread of COVID-19 which is in agreement with
494 our model.

495 The recently published model by Miller et al. (Miller et al. 2022) utilizes CDC's
496 COVIDTracer Advanced tool to provide a transmission model for SARS-CoV-2 in schools.

497 They took into account scenarios for infection in the community and public compliance to CDC
498 guidelines to mitigate COVID-19 spread. Similar to other models, they found that social
499 distancing is key to reduce spread and that the COVID-19 community case rate is crucial when
500 assessing exposure risk. Other models of COVID-19 spread in small colleges only consider
501 similar parameters as the models described above (Bahl et al. 2021). Although all these models
502 provide a good basis for predicting the optimal conditions for having in-person classes, they
503 miss key parameters incorporated in CEAT that are important to determine the most effective
504 and accurate assessment of exposure risk to COVID-19. The lessons learned from classroom
505 scenarios can also be applied to other gatherings, such as family gatherings. We demonstrated
506 that depending on the location and people's behavior, there are scenarios which have low risk
507 for viral exposure (**Fig. 3**). Currently, there are no models specifically focused on family
508 gatherings, but the literature available confirms the risk assessment analysis that CEAT
509 generates. Whaley et al. (Whaley et al. 2021) reported an assessment of COVID-19 risk
510 associated with social gatherings, specifically during birthdays. They utilized data from 2.9
511 million households from a large insurance database that included COVID-19 prevalence from
512 January 1 to November 8, 2020, and household birthdays across geographical regions in the
513 US. They estimated that increased cases of COVID-19 correlated with social gatherings (i.e.
514 birthdays), with increased cases for households in counties with higher COVID-19 prevalence.
515 This study can serve as a population confirmation for the assessment we provided for
516 gatherings with CEAT (**Fig. 3**).

517 Since the beta version release of CEAT in December 2020, we have made several additions
518 to the tool to improve it including: 1) an eddy diffusivity-based near-field concentration
519 algorithm; 2) added an infection rate calculation, 3) accounted for new SARS-CoV-2 variants,
520 3) address COVID-19 surveillance testing for groups, 4) addressed immunity within the
521 population gained from recovery or vaccination. These additional functionalities were added
522 to adapt to new information that was available since the initial release and reflect the team's
523 increased understanding of the risk dynamics related to SARS-CoV-2 transmission.

524 To determine the capability of CEAT being used by an organization to safely regulate
525 employees working in-person, we have provided an example of it being applied by the NASA
526 ARC safety office (**Fig. 4** and **Table S3**). NASA ARC adjusted parameters related to group
527 size, duration of time, and ventilation for the project to bring the exposure level to the lowest
528 possible risk. The analysis shows how NASA ARC continued to monitor the changing case
529 numbers within the community and utilized CEAT to provide the safest possible scenario for
530 essential employees to work in-person. The use of CEAT by NASA ARC represents a blueprint

531 for other organizations, businesses, and schools to use the tool to manage their organizations
532 exposure and risks to allow the organization to optimize mitigation strategies for employees to
533 work in-person with lower exposure risk to COVID-19. The case study at NASA ARC has
534 shown that as the push for employer vaccine mandates increases (The White House 2021),
535 employers can calculate the potential exposure risk reduction among their workforce compared
536 to the community. This will be especially useful for workplaces in communities with low
537 vaccination rates, where an employer vaccine mandate could have a large reduction in risk.

538 There are certain parameters in CEAT's model that will have a greater influence on the
539 assessment for exposure risk to COVID-19. As the examples we have provided show, the
540 location of the gathering makes a big impact on the outcome (i.e. indoors vs outdoors) (**Figs. 3**
541 **and 4**). This is due to the fact that the exchange of aerosols between people outdoors will
542 obviously be greatly reduced due to open circulation of the air versus in a confined space. The
543 compliance to public health guidance policies is another parameter that will greatly change the
544 outcome of the exposure risk assessment (**Figs. 3 and 4**). Lastly, the type of mask will make a
545 considerable difference on the outcome of the model. From existing literature on effectiveness
546 of masks (Brooks and Butler 2021; Howard et al. 2021; Wang et al. 2021), our model takes
547 into account that the better the mask and the greater the adherence to mask wearing results in
548 a reduction of dose ratio. (**Figs. 3 and 4**).

549 We believe that this tool and model can be easily modified and applied for guidance in
550 current and future epidemics/pandemics from respiratory pathogens. In addition to SARS-
551 CoV-2, a systematic review of the literature has shown that measles, TB, chickenpox,
552 influenza, smallpox and SARS have strong and sufficient evidence of an association between
553 their transmission and ventilation and air movement (Li et al. 2007). Accordingly, if pathogens
554 have similar transmission mechanisms through aerosols, CEAT model can be modified to
555 include the aerosol and viral dynamics to accommodate their pathogen-specific exposure risk
556 assessment. We believe that by providing CEAT to the general public and building on its
557 capabilities, will have a long lasting beneficial impact for both our current pandemic and many
558 other scenarios.

559

560 **Limitations of the Study**

561 As with any mathematical model, there will be parameters that cannot be fully captured.
562 Our model has a number of inherent limitations; nonetheless, it has been demonstrated to be
563 used to accurately predict COVID-19 exposure risk for a limited number of eleven documented

564 transmission event cases. In some of these cases key parameters were not available but were
565 instead estimated. A full validation of the model where a separate complete training set and
566 test data set were compiled and applied to the model validation.

567 Several simplifying assumptions were made in the development of CEAT that resulted in
568 more conservative results. One conservative assumption was using the highest exposed person
569 to represent all people in a group. In future versions of CEAT, we may calculate location
570 specific exposure values that account for the location of each person in the space, versus every
571 other person in the space. This approach would result in a lower group exposure estimate than
572 we currently calculate.

573 The CEAT concentration model assumes exhalations behave isotropically (i.e., they
574 disperse equally in all directions), are non-buoyant, and are continuous exhalations. In reality,
575 exhalations are more complex and may range from violent expiratory events or more regular
576 puffs (Bazant and Bush 2021). Exhalation plumes are typically anisotropic jets and have a
577 buoyant nature due to their relative warmth and higher humidity. CFD modeling has captured
578 these dynamics (Fabregat, Gisbert, Vernet, Ferré, et al. 2021; Fabregat, Gisbert, Vernet, Ferré,
579 et al. 2021; Li et al. 2022). To compensate for the fact that CEAT assumes plumes are non-
580 buoyant, which likely results in CEAT over-predicting concentrations at breathing heights, we
581 adjust the height of the near-field volume to be equal to the distance between the source and
582 the receptor, mixing the emission in all directions and in a larger near-field volume. The
583 anisotropy is more difficult to capture in a model, given that people in groups may be facing in
584 different directions at any point in time and in some events, such as a classroom, people may
585 have a more uniform directionality. Additionally, the direction of the airflow in an indoor space
586 is dependent on the flowrate characteristics of the ventilation system, geometry of the space,
587 geometry and type of air vents, doors, windows, differential heating and cooling, other fans in
588 the building, movement of people, and indoor/outdoor environment interactions. The simple
589 approach used by CEAT to arrive at a concentration, certainly could be improved upon for any
590 specific situations using CFD modeling, however the computational complexity and run times
591 would greatly increase. Experiments that included high temporal and spatial measurement of
592 CO₂ from people in a variety of indoor conditions may be useful for testing and optimizing the
593 concentration modeling approach used in CEAT. Experimentation, similar to the studies
594 conducted by Vernez et al. 2021 (Vernez et al. 2021), but using exhaled CO₂ and inert aerosols
595 as tracers, could be accomplished to compare with results obtained using CEAT's algorithms
596 to validate its concentration models and possibly calculate adjustments for the eddy diffusivity.

597 The aerosol deposition and virus decay behavior are simplistically handled in CEAT by
598 adding additional terms to the air change rate resulting in a lower concentration since the
599 effective ACH is increased. CEAT uses the same values for aerosol deposition and virus decay
600 of 0.24 hr^{-1} and 0.63 hr^{-1} , respectively, for all conditions, using the same values recommended
601 in CIRES, 2020. The deposition and virus decay rates should vary based upon environmental
602 conditions and the nature of the exhalation conditions (breathing, coughing, sneezing, singing,
603 and speaking). In future versions of CEAT, exhalation-specific deposition rates and the
604 environmental-specific decay rates (i.e., varying by humidity, temperature, and ultraviolet
605 radiation) could be calculated (Biryukov et al. 2020; Ratnesar-Shumate et al. 2020; US DHS
606 2022).

607 The lack of incorporation of different efficiencies for the different vaccines available. In
608 our model, we currently have “Protective Effectiveness of Immunity” being considered as one
609 universal number for the population being assessed. We believe that differences for efficacy
610 between the vaccines can be averaged for the overall community. Our model also lacks the
611 ability to incorporate the length of time that has passed since being vaccinated or previously
612 infected. This might change the risk assessments since we now know that for both cases the
613 levels of antibodies against SARS-CoV-2 reduce over time (Khoury et al. 2021; Marot et al.
614 2021; Yamayoshi et al. 2021). However, more research is needed to determine how this impacts
615 the protection against SARS-CoV-2, which is the reason we have not incorporated this
616 parameter into our model at the moment. Additionally, CEAT does not account for the buildup
617 of viral particles between groups utilizing the same space one after another. This limitation will
618 impact groups gathering in a room separately, but sequentially. One way to overcome this
619 limitation is for groups to allow a certain amount of time between occupancy. Calculating the
620 amount of time needed for a ventilation system to remove 99% of contaminants, like that
621 provided by the CDC for infection control in health-care facilities (CDC 2003), can allow
622 groups to calculate their exposure risk ratio during separate but successive events. Similarly,
623 groups can estimate their relative risk of back-to-back gatherings by adding the total duration
624 of all meetings throughout the day.

662 events (found in **Table 2**) to CEAT predicted infection rates. **C)** and **D)** The adjusted and

663 unadjusted scatter plot comparing the observed infection rates of known events to Wells-Riley
664 model predicted infection rates. For **A) - D)** linear fits were made to the data points and the
665 residuals of these fits are plotted underneath each plot. The R^2 values for the fits are shown in
666 the plots. **E)** Correlation plot of the observed infection rate to both the CEAT and Wells-Riley
667 adjusted predicted infection rates. Correlation with additional parameters from the event is
668 shown. The size of the nodes reflects the degree of correlation (i.e. larger the size the higher
669 the correlation). Positive correlation is related to the higher shades of red, while negative
670 correlation is related to higher shades of blue. Statistically significant correlations are denoted
671 by *** p-value < 0.001, ** p-value < 0.01, and * p-value < 0.05. **F)** Scatter plot of the exposure
672 risk for all eleven events determined by CEAT.

673

674 **Figure 3. COVID-19 Exposure Assessment for Gathering Lasting 5 Hours.** Data was
675 analyzed on January 31st, 2022 for three US counties from the lowest (Montgomery County,
676 MD) to highest (Knox County, TN) COVID-19 cases. The time was kept constant for all data
677 points which assumes an average gathering of around 5 hours. The vaccination rates and
678 population recovered rates are displayed on top of the plot for each county. Different scenarios
679 were represented for location (outdoors = triangle, indoors = circle), distancing (increasing
680 point size relates with increasing distance), and mask usage (no masks = red, average masks =
681 blue, and N95/KN95 = yellow). The background shading of the plot indicates whether the data
682 points are considered low risk (light blue), medium risk (yellow), or high risk (red) for COVID-
683 19 exposure.

684

685 **Figure 4. COVID-19 Exposure Assessment for Determining Lowest Exposure Risk for**
686 **In-Person Work by NASA Ames Research Center.** Exposure risk ratios using CEAT were
687 calculated for 73 different scenarios (i.e. various locations and operations) at NASA ARC. The
688 variables used for all ten steps are depicted for each scenario highlighting how various inputs
689 affect the exposure risk ratios. The data for this figure is available in **Table S3**.

690

691 **Figure 5. NASA Ames Research Center (ARC) Accepted Exposure Risk in Relation to**
692 **Community Case Rates.** Exposure risk ratios were calculated on a biweekly basis for 76
693 different scenarios (i.e. various locations and operations) at NASA ARC starting March 1, 2020
694 upon approval to RTOW through September 1, 2021. Biweekly reassessments included
695 changes in community conditions such as case rate, variant prevalence, and vaccination rates
696 in California. The median of all projected exposure risk ratios was calculated on a biweekly

697 basis to establish a “NASA ARC Accepted Median Exposure Risk” (blue). These values were
698 plotted along with the California state 7-day case rate per 100 thousand (orange). Notations
699 were made designating major events and/or policy changes that may have influenced trends
700 and deviations. The background shading of the plot indicates whether the data points are
701 considered low risk (light blue) or medium risk (yellow) for COVID-19 exposure.

755 *Lead Contacts*

756 Further information and requests for resources and reagents should be directed to and will
757 be fulfilled by the Lead Contacts, Afshin Beheshti (afshin.beheshti@nasa.gov) and Brian
758 Schimmoller (bschimmoller@signaturescience.com).

759

760 *Materials Availability*

761 This study did not generate new unique reagents.

762

763 ***Data and Code Availability***

764 The published article includes all datasets generated and analyzed during this study. Any
765 additional information required to reanalyze the data reported in this paper is available from
766 the lead contact upon request.

767

768 **METHOD DETAILS**

769 **Relative Dose Ratio Approach and Exposure Risk Model Derivation**

770 CEAT's relative dose ratio approach is based upon a mechanistic dose-response
771 framework. The starting point for the inhalation dose model is to use the relationship that
772 defines group-wide inhalation dose as a linear system where:

$$773 \quad E_{Group\ Dose} = \underline{C} \times \underline{Q}_{Inhalation} \times \Delta t \times Pe_{Total} \quad Eq.S1$$

774 and $\underline{Q}_{Inhalation}$ is the average inhalation rate for the group, \underline{C} is the average concentration of
775 the agent (in this case, aerosols containing SARS-CoV-2), Δt is the duration of group exposure,
776 and Pe_{Total} is the number of people exposed in the group, which we assume is equal to the
777 total number of people in the group . The $E_{Group\ Dose}$ represents the total mass of contaminant
778 that enters the respiratory tracts of all of the group by inhalation over the duration of the
779 potential exposure or event. The fate or dynamics of the virus within the respiratory tract are
780 not considered in the model and would be part of a transmission process. The critical variable
781 that must be estimated by the model is the concentration of virus-containing aerosols that
782 occurs as a result of the exhalation (i.e., breathing, speaking, coughing, singing) from people
783 who are in close proximity and build up in a room over time.

784 There are a variety of ways of estimating concentration of contaminants in the air. Several
785 commonly used methods include well-mixed box (WMB) models (Reinke and Keil 2009),
786 computational fluid dynamic (CFD) models (Anthony 2009), and gaussian dispersion models
787 (Stockie 2011). Computational fluid dynamics based models uses numerical solutions of the
788 first principle equations of fluid flow and contaminant transport that are tailored to the specific
789 geometry, scale and temporal lengths, and flow regimes, and are capable of modeling the
790 complexities of particle dynamics, inhalation, exhalation, and interaction with flows in a
791 building (Anthony 2009). Gaussian models use an explicit solution of the contaminant transport
792 equations, and are, therefore, computationally fast compared to CFD models. Gaussian models

793 are typically used at larger scale lengths (100s of meters or more) and are used in outside
794 environments, not typically used in indoor modeling (Zannetti 1990). The WMB model is a
795 simple model that can be used to estimate concentrations of contaminants in the air. It treats a
796 room as if it were a continuous stirred-tank reactor (CSTR) and uses the basic equations for
797 concentration that were developed for modeling continuous reactors in chemical engineering.

798 The WMB (or zone) approach is widely used, and, for example, is the basis for the National
799 Institutes of Standard and Technology's (NIST's) CONTAM indoor air quality model (Dols
800 and Polidoro 2015). NIST has also applied a single zone WMB approach in its Fate and
801 Transport of Indoor Microbiological Aerosols (FaTIMA), where it assumes rooms are single
802 well-mixed zones (Dols et al. 2020).

803 The basic equation for the single zone WMB is shown below:

804
$$V dt = \dot{M} dt - Q_{vent} C dt \quad Eq. S2$$

805 where V is the volume of the box, Q_{vent} is the ventilation rate (in units of volume per time)
806 through the box, and \dot{M} is the emission rate (in units of mass per time) (**Fig. S1B**).

807 If we assume the emission rate is constant starting at time equals zero, the time varying
808 equation takes the form:

809
$$C(t) = \frac{\dot{M}}{Q_{vent}} \left(1 - e^{-\frac{Q_{vent}}{V}t} \right) \quad Eq. S3$$

810 Once enough time has passed to achieve equilibrium, the model takes the simple form:

811
$$C_{eq} = \frac{\dot{M}}{Q_{vent}} \quad Eq. S4$$

812 The basic simplifying assumption of the WMB model is that it assumes that a contaminant
813 is instantaneously completely mixed throughout a volume of air. This instantaneously well-
814 mixed assumption is a significant limitation when looking to determine the exposure between
815 people in a room or space if they are in close proximity relative to the size of the room. The
816 single zone well-mixed assumption results in the same exposure no matter how close or far
817 people are located. Accordingly, methods that can assess the potential for higher concentrations
818 (and exposures) that would result between closely clustered people would be useful for
819 quantifying exposure, doses and associated risks.

820

821 **Near Field (NF) and Far Field (FF) Box Model**

822 In the field of industrial hygiene, it is recognized that the single zone box model may
823 underestimate exposures experienced by receptors (i.e., people) close to a hazard, since it

824 assumes that the concentration is instantaneously well-mixed over the volume of the room
 825 (Jaycock et al., 2011). While computational fluid dynamics is one option to resolve the spatial
 826 complexity of dispersion and mixing of a contaminant, industrial hygienists have devised a
 827 simpler way of estimating the high concentrations near a source using a “box within a box,”
 828 with an inner box or near field (NF) box containing the contaminant source and a receptor, and
 829 a larger, far field (FF), box that represents entire volume (e.g., room). (**Fig. S1C**) The time
 830 dependent concentration at the receptor is estimated by adding the NF and FF concentration
 831 contributions (Nicas 2009a; Nicas 2014).

$$832 \quad C(t) = C(t)_{NF} + C(t)_{FF} = \frac{\dot{M}}{Q_{NF}} \left(1 - e^{-\frac{Q_{NF}}{V_{NF}} \Delta t} \right) + \frac{\dot{M}}{Q_{FF}} \left(1 - e^{-\frac{Q_{FF}}{V_{FF}} \Delta t} \right) \text{ Eq. S5}$$

833 where, \dot{M} is the continuous mass release rate per minute of the contaminant of concern, Q_{NF}
 834 (or as referred to by Nicas as β) is the NF volumetric flow rate (m^3 per minute), Q_{FF} is the FF
 835 volumetric flow rate (m^3 per minute), V_{NF} is the NF volume (m^3), V_{FF} is the FF volume (or
 836 volume of the room or activity space) (m^3), and Δt (minutes) is the elapsed time since the
 837 start of the release.

838 If one assumes both boxes to be at equilibrium, the equation takes the simpler form:

$$839 \quad \underline{C}_{eq} = C_{eq,NF} + C_{eq,FF} = \frac{\dot{M}}{Q_{NF}} + \frac{\dot{M}}{Q_{FF}} \text{ Eq. S6}$$

840 Calculating the ventilation rates, Q_{NF} (or as referred to by Nicas as β) and Q_{FF} using the
 841 room volume and appropriate air change rate specific for each volume yields:

$$842 \quad \underline{C}_{eq} = \frac{\dot{M}}{V_{NF} \frac{ACH_{NF}}{60}} + \frac{\dot{M}}{V_{FF} \frac{ACH_{FF}}{60}} \text{ Eq. S7}$$

843 where ACH_{NF} is the NF air change rate (hr^{-1}), and ACH_{FF} is the FF air change rate (hr^{-1}). For
 844 the time dependent form, since the volumes in the exponential term cancel themselves out, the
 845 following results:

$$846 \quad C(t) = \frac{\dot{M}}{V_{NF} \frac{ACH_{NF}}{60}} \left(1 - e^{-\frac{ACH_{NF}}{60} \Delta t} \right) + \frac{\dot{M}}{V_{FF} \frac{ACH_{FF}}{60}} \left(1 - e^{-\frac{ACH_{FF}}{60} \Delta t} \right) \text{ Eq. S8}$$

847
 848 In the application of NF and FF models, it is recommended (Nicas 2009a; Nicas 2016) that
 849 the NF flow rate, Q_{NF} (or β), be equal to $\frac{1}{2} \times S \times FSA$ where FSA is the free surface area of
 850 the assumed NF control volume and S is a random air speed (instantaneous in random direction)
 851 at the interface of the NF and FF zones and $\frac{1}{2}$ is used assuming that half of the air volume is

852 entering the control volume and half of the air is leaving the control volume. Further, Nicas
853 recommends using $s=15.1$ meters per minute (50 feet per minute) when strong air currents are
854 present and $s=3.0$ meters per minute (10 feet per minute) when air currents are lacking near the
855 NF zone (Nicas 2014). A median random air speed for indoor office and home spaces was
856 observed by Baldwin and Maynard, 1998 (Baldwin and Maynard 1998) to be between 0.05 and 0.1
857 meters per second. Nicas, 2014 (Nicas 2014), referencing Baldwin and Maynard, 1998 (Baldwin
858 and Maynard 1998), recommends that the typical value of 0.06 meters per second (3.6 meters
859 per minute), may be used with the *FSA* approach in indoor settings. Accordingly, in ACH_{NF}
860 can be calculated using the *FSA* approach as follows:

$$861 \quad ACH_{NF} = \frac{\frac{1}{2} \times s \times FSA \times 60}{V_{NF}} \quad Eq. S9$$

862 As we will show, the *FSA* approach when applied using typical values for median random
863 airspeed did not predict concentrations that align well with measured data. Accordingly, we
864 have devised an alternative way of calculating the ACH_{NF} using an effective value for the
865 random air speed we call s_{eff} that varies with distance from the source and is derived from
866 an estimate of the eddy diffusivity. To do this we examined the gaussian/ eddy diffusivity
867 equations and show that the NF/FF equations can be equivalent in certain cases to the continuous,
868 gaussian solution of the dispersion equation when there is no advection (i.e., mean wind speed
869 is equal to zero). Through this analysis, we can formulate a NF/FF model that uses eddy
870 diffusivity rather than relying on the Baldwin and Maynard, 1998 reported random air speed to
871 provide the mixing dynamics. To illustrate this, we start with side-by-side derivations for 1) a
872 continuous point release using the gaussian approach, 2) the NN/FF model using a spherical
873 NF volume, and 3) the NN/FF model using a hexagonal prism NF volume, as shown in **Table**
874 **S4**. In all three cases, we arrive at equations for concentration that are nearly identical.
875 Assuming the same values were used for K and distance from the source, all three
876 representations would provide nearly the same result – even the hexagonal prism representation
877 since 6 is within five percent of 2π .

878 The challenge in using an eddy diffusivity model is determining the appropriate value
879 for K (Nicas 2009b). It is important to note that in the derivation of the gaussian solution, the
880 value for K is assumed to be constant over the domain (Stockie 2011). The form of the
881 equation for K that we arrive at, $K = x \cdot s$, is similar to the form suggested by
882 Venkatram and Weil, 2021 (Venkatram and Weil 2021), $K = \alpha \cdot u \cdot l$. Venkatram and
883 Weil, 2021 (Venkatram and Weil 2021) describe α as a dimensionless value that would be

884 determined experimentally; u is a representative velocity, and l was a representative length.
885 For now we will assume that $\alpha = 1$, such that in our case $K = D \cdot s$.

886 Cheng et al. 2011 (Cheng et al. 2011) show a relationship between the air change rate
887 for a room and the eddy diffusivity using experimental measurements of carbon monoxide
888 released in two indoor environments. The data from these experiments are presented in their
889 paper and in Acevedo-Bolton et al. 2012 (Acevedo-Bolton et al. 2012). These approaches
890 capture the additional turbulent kinetic energy that is added to the system through the higher
891 air changes through ventilation or increased mixing of the air (e.g., through the HVAC
892 system circulating the air) (Cheng et al. 2011; Venkatram and Weil 2021). This approach
893 provides for a constant eddy diffusivity within the room and does not suggest dependency of
894 the eddy diffusivity on the distance from the source. The recommend the eddy diffusivity
895 ($\text{m}^2 \text{sec}^{-1}$) is calculated using the mechanical ACH_{FF} (air change rate in hr^{-1}) and, V , the
896 overall volume of the room (m^3), as follows:

$$897 \quad K = (0.52 ACH_{FF}/3600 + 8.61 \times 10^{-5}) V^{2/3} \quad Eq.S10$$

898 Venkatram and Weil, 2021 (Venkatram and Weil 2021), using the same datasets suggest a
899 more simple but similar relationship:

$$900 \quad K = V^{2/3} ACH_{FF} / 3600 \quad Eq.S11$$

901 Foat, et al., 2020 (Foat et al. 2020) recommend a similar relationship that was arrived at
902 through CFD simulations over a wide of range of indoor parameters:

$$903 \quad K = 0.824 V^{2/3} N^{-2/3} ACH_{FF} / 3600 \quad Eq.S12$$

904 where N equals to the number of inlet vents for the room. Foat, et al., 2020 (Foat et al.
905 2020) looked at a range of room volumes between 50 m^3 and 5000 m^3 , floor aspect ratios
906 (length/width) between 1-3, height/(floor area)² ratio between 0.1 and 1.5, and air change rate
907 between 0.6 and 19.9 hr^{-1} . In most modern buildings, the number of vents would increase with
908 increasing volume or area. Across the range of 235 scenarios that were modeled, the number
909 of vents per 100 m^2 of area ranged from 3.8 to 8 vents per 100 m^2 (excluding the four extreme
910 values of approximately 50 vents per 100 m^2), and averaged 4.6 vents per 100 m^2 . To limit the
911 number of variables that the user needs to know or determine to use CEAT, we replace N with
912 a relationship between the area of the room and a reasonable number of vents per unit area,
913 examining values ranging from 3 to 8 vents per 100 m^2 .

914 By combining the two representations of the eddy diffusivity equations and assuming that
 915 the product of D and s is a constant, we can calculate an effective velocity s_{eff} (in $m \text{ min}^{-1}$)
 916 that is consistent with a constant eddy diffusivity at all distances from the source.

917
$$D \cdot s_{eff} = K \quad Eq.S13$$

918

919
$$s_{eff} = \frac{K}{D} \quad Eq.S14$$

920

921 Below are the Venkatram and Weil, 2021(Venkatram and Weil 2021) and Foat, et al., 2020
 922 (Foat et al. 2020) solutions for K expressed as s_{eff} (in $m \text{ min}^{-1}$):

923
$$s_{eff} = \frac{V^{2/3} ACH_{FF} / 60}{D} \quad Eq.S15$$

924

925
$$s_{eff} = \frac{0.824 V^{2/3} N^{-2/3} ACH_{FF} / 60}{D} \quad Eq.S16$$

926

927 Since all three K and ACH relationships are constant with respect to D , the product of $D \cdot$
 928 s_{eff} is a constant, thus any change in s is inversely proportional with the change in D .
 929 Therefore, as D increases moving away from a source, the value of s_{eff} decreases.

930 Now we come back to the relationship of $K = \alpha \cdot u \cdot l$ or expressed in our variables
 931 $K = \alpha \cdot s_{eff} \cdot D$ and define α , adjustments for the eddy diffusivity, as a means of
 932 capturing any dependency of K on distance from the source and adjustment to the dependence
 933 on ACH in the form (should measurement data indicate there are dependencies):

934
$$\alpha = \lambda x^\mu \cdot \varepsilon ACH_{FF}^\gamma \quad Eq.S17$$

935

936 Substituting the equation for K into our original equation and rearranging so that the FSA
 937 of the hexagon is still calculated, we arrive at:

938
$$\underline{C}_{pq} = \frac{\dot{M}}{\frac{\varepsilon}{2}(D^2 + D h_{bz}) \alpha \cdot s_{eff}} \quad Eq.S18$$

939 and ACH_{NF} is

940
$$ACH_{NF} = \frac{\frac{6}{2} (D^2 + D h_{bz}) \alpha \cdot s_{eff} \cdot 60}{V_{NF}} \quad Eq.S20$$

941 To calculate an average inhalation dose over a period of time, assuming that the initial
942 concentration is zero ($C(0) = 0$) from a single source, we estimate the average dose by
943 calculating the concentration at the midpoint of the duration, $\frac{\Delta t}{2}$.

$$944 \quad \underline{C}_{AVE} = \frac{\dot{M}}{V_{NF} \frac{ACH_{NF}}{60}} \left(1 - e^{-\frac{ACH_{NF}\Delta t}{60 \cdot 2}} \right) + \frac{\dot{M}}{V_{FF} \frac{ACH_{FF}}{60}} \left(1 - e^{-\frac{ACH_{FF}\Delta t}{60 \cdot 2}} \right) \text{ Eq. S21}$$

945 As the duration increases, the factors $\left(1 - e^{-\frac{ACH_{NF}\Delta t}{60 \cdot 2}} \right)$ and $\left(1 - e^{-\frac{ACH_{FF}\Delta t}{60 \cdot 2}} \right)$ will converge
946 on 1. Given that ACH_{NF} is likely greater than ACH_{FF} the factor $\left(1 - e^{-\frac{ACH_{NF}\Delta t}{60 \cdot 2}} \right)$ will converge
947 faster than the factor $\left(1 - e^{-\frac{ACH_{FF}\Delta t}{60 \cdot 2}} \right)$. Meaning, the near field term will achieve equilibrium
948 faster than the far field term.

949

950 **Validation the of the Single Source Equation with Measurement Data**

951 We compare predictions calculated using Equation S20 to measurements of chemical and
952 aerosol releases in indoor environments that characterize concentrations at various distances
953 from sources. We included data from carbon monoxide (CO) releases in two homes (Acevedo-
954 Bolton et al. 2012; Cheng et al. 2014)(Acevedo-Bolton, et al., 2012), toluene releases in a test
955 chamber (Zhang et al. 2009), benzene releases in an industrial environment (Nicas et al. 2007)
956 and liquid aerosols containing lactose released to simulate an actual COVID-19 transmission
957 incident that occurred in a Swiss court room (Vernez et al. 2021). The study of carbon monoxide
958 (CO) releases (Cheng et al. 2011; Acevedo-Bolton et al. 2012; Cheng et al. 2014) occurred in
959 two residential homes where seventeen separate 8-hour tests with continuous emission rates
960 were conducted. Measurement distances from the source ranged from 0.25 meters through to
961 5 meters. The chamber tests conducted by Zhang, et al., 2007 involved simultaneous
962 measurements at four points that were 0.1 meters from a release point. Across the dataset, the
963 distance from the source varied between 0.1 meters and 5 meters, the room volumes varied
964 between 3 m^3 and $50,000 \text{ m}^3$, and the air changes per hour between 0.17 and 218 hr^{-1} . We also
965 examined an example case that was presented by Nicas 2009 (Nicas 2009a), where the
966 conventional NF/FF approach is applied.

967 Examination of the performance of the three eddy diffusivity models (assuming that no
968 adjustment is necessary and that value of $\alpha = 1$ for the expression in **Eq. S17**) shows that the
969 best model above 0.75 hr^{-1} is the Foat, et al., 2020 (Foat et al. 2020) equation with an $R^2 = 0.94$

970 (Fig. S2B) when the number of vents per 100 m² is equal to 4. The best model below 0.75 hr⁻¹
971 is the Venkatram and Weil, 2021 (Venkatram and Weil 2021) model, with an R² = 0.92 (Fig.
972 S2A). Acevedo-Bolton, et al. 2012 (Acevedo-Bolton et al. 2012) show in their analysis that the
973 carbon monoxide sensors (measuring at 15 second time intervals) at 0.25 meters were likely
974 seeing concentrations that were above the upper limits of the instrument's data logger (between
975 128 and 150 ppm), resulting in an underestimate of average reported concentration. Our model
976 systematically overpredicts the concentrations, as compared to the measured data, at 0.25
977 meters and to a lesser degree at 0.5 meters. Consequently, we remove the 0.25 data from the
978 dataset.

979 The major difference between the two models is the inclusion of a factor that captures the
980 number of vents. It is reasonable to assume that spaces with very low air change rates do not
981 have vents (or do not have functional vents), so the inclusion of the number of vents in the
982 equation is not meaningful and in low air change rates the Venkatram and Weil,
983 2021 (Venkatram and Weil 2021) equation is sufficient. Also, the lower limit of the air change
984 rate in the Foat, et al., 2020 (Foat et al. 2020) dataset was 0.6 hr⁻¹ and only three of the 235
985 modeled scenarios analyzed had air change rates less than 0.75 hr⁻¹. Given that (1) most
986 commercial and institutional facilities will have air change rates that are greater than 1 hr⁻¹, (2)
987 would have an additional air change rate term to account for HVAC recirculation and filtration,
988 and (3) these facilities' HVAC systems will include inlet vents, it is important to use a method
989 that addresses the effect of vents on dispersion and is accurate at high air change rates. Also,
990 given that the risks of COVID-19 exposure are highest when the air change rates are low such
991 as when natural ventilation is relied upon, it is important to have a method that works well in
992 those conditions. The Acevedo-Bolton, et al., 2012 (Acevedo-Bolton et al. 2012) dataset and
993 the Venkatram and Weil, 2021 (Venkatram and Weil 2021) estimate for eddy diffusivity cover
994 those low air change rate scenarios.

995 Based upon these factors and our analysis, in the CEAT model, we use the unadjusted
996 Venkatram and Weil, 2021 (Venkatram and Weil 2021) model to estimate eddy diffusivity at
997 air change rates at or below 0.75 hr⁻¹ and the Foat, et al., 2020 model (Foat et al. 2020) to
998 estimate eddy diffusivity above 0.75 hr⁻¹ with an assumption of 4 vents per 100 m². The results
999 of this combined model compared to the measured data, are shown in Fig. S2C.

1000 Multiple Sources

1001 Equation S21 provides an estimate of the average concentration from one person's emission
1002 at a receptor, but not the contribution of how multiple people's emissions would affect the

1003 concentration. To address multiple sources in combination, the additivity property of the
 1004 “superposition principle of linear systems” can be applied (Illingworth 1991), which enables
 1005 that the effect of each person’s emissions at a receptor can be calculated separately and
 1006 summed. The superposition principle has been applied to outdoor air pollution dispersion
 1007 modeling (Stockie 2011) and provides the theoretical basis for modeling complex scenarios
 1008 involving multiple emission sources in outdoor gaussian plume models such as EPA’s
 1009 AIRMOD (US EPA 2019). The logic is, therefore, if a NF and FF approach can be used to
 1010 estimate the higher concentration in the close proximity of one person to another person, then
 1011 if n people were added to the system, and n additional NF boxes were added, the terms would
 1012 be added to the equation for each person (i.e., emission source), with each being independent
 1013 and summing to total concentration, as shown below:

$$1014 \quad C_{AVE} = \sum_{Pe=1}^N \left[\left(\frac{\dot{M}}{V_{NF} \frac{ACH_{NF}}{60}} \right) \left(1 - e^{-\frac{ACH_{NF}\Delta t}{60^2}} \right) + \left(\frac{\dot{M}}{V_{FF} \frac{ACH_{FF}}{60}} \right) \left(1 - e^{-\frac{ACH_{FF}\Delta t}{60^2}} \right) \right]_N$$

1015 *Eq. S22*

1016 The superposition principle also includes a homogeneity property, which allows us to
 1017 apply a scalar factor across all emission sources resulting in the concentration at the receptor
 1018 changing proportionally to the value of the scalar. This property provides the conceptual basis
 1019 that allows one to conclude that if the emission rate from each source is increased or decreased
 1020 by a factor, that one could assume the concentration would increase or decrease by the same
 1021 factor. The scalar could also be the product of several scalars, including a probability factor.
 1022 CEAT will use this property defining a scalars, \dot{M} and φ (phi), to adjust both the emission rate
 1023 and the probability of the emission rate, assuming that the emission rate and the probability of
 1024 emission rate are constant for all sources for a given scenario, resulting in the following
 1025 equation:

$$1026 \quad C_{AVE} = \varphi \dot{M} \times \sum_{So=1}^N \left[\left(\frac{1}{V_{NF} \frac{ACH_{NF}}{60}} \right) \left(1 - e^{-\frac{ACH_{NF}\Delta t}{60^2}} \right) + \left(\frac{1}{V_{FF} \frac{ACH_{FF}}{60}} \right) \left(1 - e^{-\frac{ACH_{FF}\Delta t}{60^2}} \right) \right]_N$$

1027 *Eq. S23*

1028 In a two-source system with one receptor, where the distance between the two receptors
 1029 and the source equidistant shown in **Fig. S3A**, the following equation can be written:

$$\begin{aligned}
 1030 \quad C_{AVE} &= \varphi \dot{M} \times \sum_{So=1}^2 \left[\left(1 - e^{-\frac{ACH_{NF}\Delta t}{60 \cdot 2}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF}}{60}} \right) \right. \\
 1031 \quad &\left. + \left(1 - e^{-\frac{ACH_{FF}\Delta t}{60 \cdot 2}} \right) \left(\frac{1}{V_{FF} \frac{ACH_{FF}}{60}} \right) \right] \text{ Eq. S24}
 \end{aligned}$$

1032 Using a hexagonal prism for the NF volume allows one to place the system of equations on
 1033 a regular grid of equidistant triangles (**Fig S3A**). Using a regular grid of equidistant triangles,
 1034 as compared to a regular rectangular grid, has advantages since all nodes are equidistant from
 1035 their nearest neighbors. This equidistant neighbor feature is particularly useful given the
 1036 objective to assess various distancing options. The use of a triangular grid allows one to
 1037 conveniently draw a hexagonal prism that is made up of six triangular prisms that approximates
 1038 a cylinder, with each centered on the six closest nodes to the receptor, (**Fig. S3B**). The
 1039 orientation of the triangular prism within the box makes no difference to the calculations.
 1040 Accordingly, we can rotate each of the triangular prisms 180 degrees for visual convenience
 1041 (**Fig. S3C**). We do this because we can define the system identically from two perspectives,
 1042 the source view and the receptor view.

1043 The system shown in **Fig. S3D** can be used to evaluate both the NF and FF concentrations
 1044 from up to six sources at the receptor in the center, using the equation below.

$$\begin{aligned}
 1045 \quad C_{AVE} &= \varphi \dot{M} \times \sum_{So=1}^6 \left[\left(1 - e^{-\frac{ACH_{NF-1st}\Delta t}{60 \cdot 2}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-1st}}{60}} \right) \right. \\
 1046 \quad &\left. + \left(1 - e^{-\frac{ACH_{FF}\Delta t}{60 \cdot 2}} \right) \left(\frac{1}{V_{FF} \frac{ACH_{FF}}{60}} \right) \right] \text{ Eq. S25}
 \end{aligned}$$

1047 We can calculate the ACH_{NF} using the equation derived earlier for a hexagon:

$$1048 \quad ACH_{NF-1st Ring} = \frac{\frac{6}{2} (D^2 + D h_{bz}) \alpha \cdot s_{eff} \cdot 60}{V_{NF}} \text{ Eq. S26}$$

1049 By substituting for the V_{NF} ,

$$1050 \quad ACH_{NF-1st Ring} = \frac{\frac{6}{2} (D^2 + D h_{bz}) \alpha \cdot s_{eff} \cdot 60}{\frac{6}{2} (D^2 + D h_{bz})} \text{ Eq. S27}$$

1051 Which simplifies to:

$$1052 \quad ACH_{NF-1st Ring} = \alpha \times s_{eff} \times \left(\frac{1}{h_{bz}} + \frac{1}{D} \right) \times 60 \text{ Eq. S28}$$

1053 In the same way that a six source system was devised, a 12-source system that still keeps
 1054 each person in the system D distance apart, but in this case is located two D away from the
 1055 receptor. In this case, instead of a hexagon, a dodecagonal prism (12-sided prism) is drawn
 1056 (Fig. 3F). In the 12-source system, we take 1/12th of the emissions and use 1/12 of the total
 1057 dodecagonal prism volume. The ACH_{NF} is calculated using the dimension of the 1/12 triangular
 1058 wedge which is derived as follows.

$$1059 \quad ACH_{NF-2nd} = \frac{\frac{1}{2} \times \alpha \times s_{eff} \times (2 \times 0.933(D))^2 + h_{bz} \times D}{0.933(D)^2 (h_{bz})} \times 60 \quad Eq.S29$$

1060 Which simplifies to:

$$1061 \quad ACH_{NF-2nd} = \alpha \times s_{eff} \times \left(\frac{1}{h_{bz}} + \frac{1}{1.866 \times D} \right) \times 60 \quad Eq.S30$$

1062 Successive rings, out to nine rings are included in CEAT, to allow up to a maximum of 270
 1063 people. Each ring adds 6 additional people more than the previous ring (i.e, the first ring holds
 1064 6 people, the second ring holds 12 people, the third ring holds 18, etc.) (Fig S3E). Table S5
 1065 has the equations for the area of each of the triangular prisms, along with the equation used to
 1066 calculate the ACH_{NF} for each ring.

1067 Applying the superposition principle, the contribution of each person on the receptor at the
 1068 center can be calculated. Going out to 60 sources (four rings) we get:

$$1069$$

$$1070 \quad C_{AVE} = \phi \dot{M} \times \left(\sum_{S_0=1}^6 \left(1 - e^{-\frac{ACH_{NF-1st}\Delta t}{60 \times \frac{1}{2}}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-1st}}{60}} \right) + \left(1 - \right. \right.$$

$$1071 \quad \left. \left. e^{-\frac{ACH_{FF}\Delta t}{60 \times \frac{1}{2}}} \right) \left(\frac{1}{V_{FF} \frac{ACH_{FF}}{60}} \right) + \right.$$

$$1072 \quad \left. \sum_{S_0=7}^{18} \left(1 - e^{-\frac{ACH_{NF-2nd}\Delta t}{60 \times \frac{1}{2}}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-2nd}}{60}} \right) + \left(1 - e^{-\frac{ACH_{FF}\Delta t}{60 \times \frac{1}{2}}} \right) \left(\frac{1}{V_{FF} \frac{ACH_{FF}}{60}} \right) + \right.$$

$$1073 \quad \left. \sum_{S_0=19}^{36} \left(1 - e^{-\frac{ACH_{NF-3rd}\Delta t}{60 \times \frac{1}{2}}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-3rd}}{60}} \right) + \left(1 - e^{-\frac{ACH_{FF}\Delta t}{60 \times \frac{1}{2}}} \right) \left(\frac{1}{V_{FF} \frac{ACH_{FF}}{60}} \right) + \right.$$

$$1074 \quad \left. \sum_{S_0=37}^{60} \left(1 - e^{-\frac{ACH_{NF-4th}\Delta t}{60 \times \frac{1}{2}}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-4th}}{60}} \right) + \left(1 - e^{-\frac{ACH_{FF}\Delta t}{60 \times \frac{1}{2}}} \right) \left(\frac{1}{V_{FF} \frac{ACH_{FF}}{60}} \right) \right) \quad Eq.S31$$

1075 The formula may be simplified by pulling out the factors common in the two terms and
 1076 rearranging as follows:

$$\begin{aligned}
 1077 \quad C_{AVE} &= \varphi \dot{M} S_{O_{Total}} \left(1 - e^{-\frac{ACH_{FF}\Delta t}{60}} \right) \left(\frac{1}{V_{FF} \frac{ACH_{FF}}{60}} \right) + \varphi \dot{M} \left(\sum_{S_o=1}^6 \left(1 - \right. \right. \\
 1078 \quad & e^{-\frac{ACH_{NF-1st}\Delta t}{60}} \left. \left. \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-1st}}{60}} \right) + \right. \\
 1079 \quad & \sum_{S_o=7}^{18} \left(1 - e^{-\frac{ACH_{NF-2nd}\Delta t}{60}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-2nd}}{60}} \right) + \\
 1080 \quad & \sum_{S_o=19}^{36} \left(1 - e^{-\frac{ACH_{NF-3rd}\Delta t}{60}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-3rd}}{60}} \right) + \\
 1081 \quad & \left. \sum_{S_o=37}^{60} \left(1 - e^{-\frac{ACH_{NF-4th}\Delta t}{60}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-4th}}{60}} \right) \right) \text{ Eq. S32}
 \end{aligned}$$

1082 Calculating the effective ACH_{FF} and ACH_{NF} to address sinks and turbulence

1083 For the purposes of calculating the far field concentration term, the ACH_{FF} should include
 1084 any mechanisms that remove air from the space (e.g., natural ventilation, infiltration
 1085 mechanical ventilation), mechanisms that remove the contaminant from the space (e.g.,
 1086 filtration and deposition), and mechanisms inactivate contaminants (e.g., reaction, temperature,
 1087 humidity, radiation).

$$\begin{aligned}
 1088 \quad ACH_{FF} &= ACH_{Nat.l Vent} + ACH_{Infiltr.} + ACH_{Mech.Vent} + ACH_{HVAC Re.} + ACH_{Inact.} \\
 1089 \quad &+ ACH_{Dep} \text{ Eq. S33}
 \end{aligned}$$

1090 The $ACH_{HVAC Re.}$ be based upon the flow rate and the portion of the recirculated air from which
 1091 any contaminants has been removed ($ACH_{HVAC Re} \times Ef_{Filter}$):

$$\begin{aligned}
 1092 \quad ACH_{FF} &= ACH_{Nat.l Vent} + ACH_{Infiltr.} + ACH_{Mech.Vent} + ACH_{HVAC Re.} \times Ef_{Filter} \\
 1093 \quad &+ ACH_{Inact.} + ACH_{Dep} \text{ Eq. S34}
 \end{aligned}$$

1094 For the purposes of calculating the eddy diffusivity, the ACH_{FF} should only include
 1095 mechanisms that result in actual air flow. So the $ACH_{Inact.}$ and ACH_{Dep} have not been
 1096 included and the unreduced $ACH_{HVAC Recirc}$ should be used, as shown.

$$1097 \quad ACH_{FF Eddy Diff} = ACH_{Nat.l Vent} + ACH_{Infiltr.} + ACH_{Mech.Vent} + ACH_{HVAC Re.} \text{ Eq. S35}$$

1098 For the final ACH_{NF} , the $ACH_{Inact.}$ and ACH_{Dep} should be added back in, as shown below
 1099 for the 1st Ring of sources:

1100
$$ACH_{NF-1st\ Ring} = \alpha \times s_{eff} \times \left(\frac{1}{h_{bz}} + \frac{1}{D} \right) \times 60 + ACH_{Inact.} + ACH_{Dep} \text{ Eq.S36}$$

1101 **Dose Model**

1102 As stated earlier, we employ a basic inhalation dose model:

1103
$$\underline{D}_{Quanta} = \underline{C}_{AVE} \times Q_{inhale} \times \Delta t \text{ Eq.S37}$$

1104 Where, \underline{D}_{Quanta} is the quantity of inhaled infectious material, \underline{C}_{AVE} is average air
1105 concentration over the duration (mass/m³), Q_{inhale} the inhalation rate (m³/min), and Δt is the
1106 duration of exposure (min).

1107 Since we are looking at this model from a worker safety perspective, we can also look at
1108 the total inhalation dose of all people in an activity space by multiplying the total number of
1109 people, assuming we are using, ideally, an average concentration and the same duration in the
1110 activity space.

1111
$$\underline{D}_{Quanta} = \underline{C}_{AVE} \times Q_{inhale} \times \Delta t \times Pe_{Total} \text{ Eq.S38}$$

1112 The concentration contributions are calculated for a person assumed to be at the center of
1113 a triangular grid where people are spaced equidistantly (based upon the distancing specified).
1114 We assume the concentration at the center is representative for all people in the group since: 1)
1115 each person's location is likely not static during the activity and 2) exposure is driven mostly
1116 by the close-in sources (i.e., other people) and all people have close-in sources.

1117 If we include mask effectiveness in the model, recognizing that there is an effect on both
1118 the inhalation side ($1 - Ef_{in}$) and on the exhalation side ($1 - Ef_{out}$), the equation takes the
1119 following form:

1120
$$\underline{D}_{Quanta} = (1 - Ef_{out}) \times C_{AVE} \times Q_{inhale} \times (1 - Ef_{in}) \times \Delta t \times Pe_{Total} \text{ Eq.S39}$$

1121 This equation calculates the total inhalation dose that a worst-case person (located at a
1122 receptor at the center of all rings) would receive if all people were emitting at a rate \dot{M} for the
1123 exposure duration. It assumes that all people are emitters (i.e., infected), when in fact only a
1124 few may be emitters. Based upon the *homogeneity property* of the *principle of superposition*,
1125 ϕ , in the expanded dose equation can be the likelihood that a person is infected, as shown
1126 below.

1127
$$\underline{D}_{Quanta} = (1 - Ef_{out}) \times Q_{inhale} \times (1 - Ef_{in}) \times \Delta t \times Pe_{Total} \times$$

$$\begin{aligned}
 & (\varphi \dot{M} Pe_{Emitting} \left(1 - e^{-\frac{ACH_{FF}\Delta t}{60}} \right) \left(\frac{1}{V_{FF} \frac{ACH_{FF}}{60}} \right) + \varphi \dot{M} \left(\sum_{Pe=1}^6 \left(1 - \right. \right. \\
 & e^{-\frac{ACH_{NF-1st}\Delta t}{60}} \left. \left. \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-1st}}{60}} \right) + \right. \\
 & \sum_{Pe=7}^{18} \left(1 - e^{-\frac{ACH_{NF-2nd}\Delta t}{60}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-2nd}}{60}} \right) + \\
 & \sum_{Pe=19}^{36} \left(1 - e^{-\frac{ACH_{NF-3rd}\Delta t}{60}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-3rd}}{60}} \right) + \\
 & \left. \sum_{Pe=37}^{60} \left(1 - e^{-\frac{ACH_{NF-4th}\Delta t}{60}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-4th}}{60}} \right) \dots \right) \text{ Eq. S40}
 \end{aligned}$$

or written more succinctly,

$$\begin{aligned}
 \underline{D}_{Quanta} &= (1 - Ef_{out}) \times Q_{inhale} \times (1 - Ef_{in}) \times \Delta t \times Pe_{Total} \times \varphi \dot{M} \\
 &\times \sum_1^{Pe_{Total}-1} (FF_{Factor} + NF_{Factor}) \text{ Eq. S41}
 \end{aligned}$$

where,

$$\begin{aligned}
 FF_{Factor} &= \left(1 - e^{-\frac{ACH_{FF}\Delta t}{60}} \right) \left(\frac{1}{V_{FF} \frac{ACH_{FF}}{60}} \right) \text{ Eq. S43} \\
 NF_{Factor} &= \sum_{Pe=1}^6 \left(1 - e^{-\frac{ACH_{NF-1st}\Delta t}{60}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-1st}}{60}} \right) + \\
 &\sum_{Pe=7}^{18} \left(1 - e^{-\frac{ACH_{NF-2nd}\Delta t}{60}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-2nd}}{60}} \right) + \\
 &\sum_{Pe=19}^{36} \left(1 - e^{-\frac{ACH_{NF-3rd}\Delta t}{60}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-3rd}}{60}} \right) + \\
 &\sum_{Pe=37}^{60} \left(1 - e^{-\frac{ACH_{NF-4th}\Delta t}{60}} \right) \left(\frac{1}{V_{NF} \frac{ACH_{NF-4th}}{60}} \right) \dots \text{ Eq. S44}
 \end{aligned}$$

Additional terms can be added to Eq. S44 for each hexagonal ring as more people are added. CEAT allows up to 250 people.

1144 **Impact of Prevalence of Infection in Community**

1145 Critical to the exposure assessment is the consideration of the likelihood that any individual
1146 member of the group is infectious at the start of the scenario or modeled event, with the
1147 likelihood of infection represented by the variable φ . In the CEAT model, the range of
1148 likelihood of infectiousness in the group can range from 1.0 (certain infectiousness) on the high
1149 end, to a value on the low end that is 100 times less than what is estimated as the community
1150 average infectiousness. In all of the cases, we assume that at least one person is not infectious,
1151 so the population that could be infectious is the size of the group, P_e , minus 1.

1152 We estimate the community average infectiousness by using the reported 7-day average
1153 per 100,000 of diagnosed cases ($Cases_{Per\ 100000}$), an estimate of the ratio of the undiagnosed
1154 cases over the diagnosed cases (R_{Undiag}), and the average length of an infectiousness in days,
1155 (D_{Inf}), multiplied by the subgroup factor, which is the adjustment of the subgroup's rate of
1156 infectiousness as compared to the rate of infectiousness of the community.

$$1157 \quad \varphi = \left(1 - \left(1 - R_{Undiag} \times \frac{Cases_{Per\ 100000}}{100,000}\right)^{D_{Inf}}\right) 100,000 \times \text{Group Factor} \quad Eq. S45$$

1158 We assume that within a community, the population can be subdivided into subpopulations
1159 as follows:

- 1160 1. Group Factor = 0.01 The Group is composed of people who, prior to the event are
1161 estimated as having a likelihood COVID-19 infection that is 100 times lower than the
1162 community's average due to their adhering to public health guidance on distancing,
1163 masking, and exposure to crowds/people.
- 1164 2. Group Factor = 0.1 The Group is composed of people who, prior to the event are
1165 estimated as having a likelihood COVID-19 infection that is 10 times lower than the
1166 community's average due to their adhering to public health guidance on distancing,
1167 masking, and exposure to crowds/people.
- 1168 3. Group Factor = 1 The Group is composed of people who, prior to the event are
1169 estimated as having a likelihood COVID-19 infection that is equal to the community's
1170 average.
- 1171 4. Group Factor = 0.1 The Group is composed of people who, prior to the event are
1172 estimated as having a likelihood COVID-19 infection that is 10 times higher than the
1173 community's average due to their not adhering to public health guidance on distancing,
1174 masking, and exposure to crowds/people.
- 1175 5. $\varphi = 1$ The group is composed of people who are known to be infectious.

1176 **Impact of Variants**

1177 We handle the current community prevalence of variants and the relative infectiousness of
1178 the prevalent variants by assuming that some variants may be significantly more or less
1179 transmissible than other variants. For the fraction of total cases of more infectious variants, we
1180 can adjust the fractional exposure upward or downward to account for its infectiousness.

1181

1182 **Efficacy of Immunity**

1183 Immunities, including vaccination and recovered cases, are addressed in two ways:

- 1184 1. It reduces the rate of virus shedding of immunized persons who do become infected,
1185 thus reducing the emission rate, \dot{M} , for the fraction of people with immunity; this is
1186 based upon a 3 times reduction in shedding observed by (Levine-Tiefenbrun et al.
1187 2021).
- 1188 2. The immunity is treated as a barrier to infection with an effectiveness that is equal to
1189 its published efficacy based conceptually on the model used by the EPA for dose and
1190 exposure definition (US EPA 2019).

1191 We are assuming that immunity gained by recovery from COVID is equal to the immunity
1192 gained from vaccination.

1193

1194 **Efficacy of Testing**

1195 We address the efficacy and timing of testing regimes, relative to the days an individual is
1196 expected to be infectious. We assume that if an individual is infectious, at the time of the event,
1197 the timing of the infection prior to the event is a uniform distribution. For example, if $D_{Inf} =$
1198 5, and they were tested three days prior to the event, there is a $3/5$ chance they were infected
1199 when they were tested and a $2/5$ chance they got infected after they were tested (in the two
1200 subsequent days before the event). Assuming a testing false negative rate ($R_{False Neg.}$) of 10%,
1201 the testing adjustment factor, which assumes testing was performed three days before the event,
1202 is computed as follows:

- 1203 • If $D_{Inf} < 3$, there is no adjustment to the likelihood that an individual is infectious
1204 because testing was performed prior to anyone becoming infectious.
- 1205 • If the $D_{Inf} \geq 3$, the testing adjustment is computed as the
1206 weighted likelihood of either (a) having been infected at the

1207 time of testing *and* obtaining a false negative test or (b) becoming infected after
 1208 the test:

$$1209 \quad Test_{Adjust} = \frac{(D_{Inf} - 2)}{D_{Inf}} R_{False Neg.} + \frac{2}{D_{Inf}}$$

1210 where $R_{False Neg.}$ is currently set to 0.10.

1211 **Relative Dose Ratio Approach: How we establish the baseline**

1212 Rather than directly calculating a dose-response, we use a comparative dose approach. We
 1213 compare all scenarios to a baseline scenario discussed in **Table S2**. The model's results are
 1214 aligned with the US OSHA classifications of exposure risks (US OSHA 2020), by
 1215 benchmarking the dose calculations to a baseline scenario that is considered high risk by US
 1216 OSHA. We define the baseline scenario to represent a person (i.e., medical worker) who is
 1217 exposed to a COVID-19 infected person. We apply assumptions to this scenario, addressing
 1218 each of the factors in **Table S2**, to arrive at a baseline inhalation dose value. The inhalation
 1219 dose for other scenarios is compared to the baseline dose by a simple ratio. Below is the full
 1220 ratio equation with the “*i th*” scenario in the numerator and the baseline (BL) in the
 1221 denominator. We can rearrange the terms in each of the *i* scenario ($E_{mass i}$) and the baseline
 1222 ($E_{mass BL}$):

$$1223 \quad \frac{D_{Quanta i}}{D_{Quanta BL}} = \frac{\varphi_i}{\varphi_{BL}} \times \frac{\dot{M}_i}{\dot{M}_{BL}} \times \frac{\sum_1^{(Pe_{total}^{-1})}}{\sum_1^{(Pe_{total}^{-1})}} \frac{(FF_{Factor} + NF_{Factor})_i}{(FF_{Factor} + NF_{Factor})_{BL}} \times \frac{(1 - Ef_{out})_i}{(1 - Ef_{out})_{BL}}$$

$$1224 \quad \times \frac{(1 - Ef_{in})_i}{(1 - Ef_{in})_{BL}}$$

$$1225 \quad \times \frac{Q_{inhalation i}}{Q_{inhalation BL}} \times \frac{Pe_{Exposed i}}{Pe_{Exposed BL}} \times \frac{\Delta t_i}{\Delta t_{BL}} \times \frac{Variant_{Adj i}}{Variant_{Adj BL}} \times \frac{Immunity_{Adj i}}{Immunity_{Adj BL}} \times \frac{Test_{Adj i}}{Test_{Adj BL}}$$

1226 *Eq. S46*

1227 **Emission Rate Approach**

1228 Deterministic dose-response models provide estimations of the intake dose and estimations
 1229 of the probability of infection for the intake dose. These models require a means of quantifying
 1230 the dose and quantifying the pathogen-host interaction via a dose response (i.e., a *tolerance*
 1231 *dose* – the dose above which someone is certain to be infected or a *threshold dose* – minimum
 1232 dose needed to initiate a chance of infection in any person) (Sze To and Chao 2010). To
 1233 calculate risks using a dose-response approach, similar to what was done by Parhizkar, et al.,
 1234 2021, the following is needed: (1) an explicit mass rate or particle count rate emitted from an

1235 infected person, (2) information on particle size emitted and particle size distribution, and (3)
1236 the explicit response threshold dose or tolerance dose. Determining these data requires
1237 environmental measurement and epidemiological studies of transmission. While CEAT is also
1238 based upon a deterministic dose-response framework, it does not use explicit values for
1239 emission rate and dose response. Instead it calculates a dose ratio (using Equation S44), based
1240 upon comparing a baseline scenario that has been defined as high risk to an evaluated scenario
1241 (i.e., i^{th} scenario). This simplification provides a means to rapidly deploy a comprehensive risk
1242 model during an infectious disease outbreak ahead of public health and medical authorities
1243 having detailed data on the explicit viral emission rates and dose responses. The CEAT model
1244 does, however, require that a public health authority (e.g., Occupational Safety and Health
1245 Administration (OSHA), Centers of Disease Control and Prevention (CDC), or other
1246 governmental health department) or other expert defines an exposure and dose scenario that is
1247 consistent with high risk exposure. In CEAT, we have used the OSHA classifications of
1248 exposure risks (US OSHA 2020) for this purpose.

1249 While the ratio model does not directly use Wells-Riley approach, it does benefit from the
1250 data that have been empirically-derived from use of the Wells-Riley approach, allowing us to
1251 adjust the CEAT dose ratio results and exposure risk results for various activities and
1252 vocalization intensities. We use the back-calculated quanta per hour from Buonanno, et al.,
1253 2020a and Buonanno, et al., 2020b to inform the ratio of emission rates, $\frac{\dot{M}_i}{\dot{M}_{BL}}$. We make the
1254 assumption that these empirically-derived ratios would be correlated with explicit mass or
1255 particle count ratios that would be appropriate for deterministic dose-response models.

1256 It is instructive to note that the CEAT approach does not require a means of varying the
1257 emission rate ratios. If Wells-Riley-derived emissions for various activities and vocalization
1258 intensities were not available, the assumption could be made that emission rate was constant
1259 (i.e., $\frac{\dot{M}_i}{\dot{M}_{BL}} = 1$). All of the other ratio factors in Eq 46 could still be used to evaluate the i^{th} dose
1260 scenario versus the baseline scenario. The majority cases that the CEAT was employed
1261 assumed that the Step 5 vocalization intensity was “standing and speaking” which uses in $\frac{\dot{M}_i}{\dot{M}_{BL}} =$
1262 1 in the model’s calculations. The fact that Wells-Riley-derived data are not essential to use
1263 CEAT is a benefit of the CEAT approach.

1264

1265 **QUANTIFICATION AND STATISTICAL ANALYSIS**

1266 **Gathering Scenario**

1267 To determine the gathering scenario, we considered three different counties for the date of
1268 1/31/2022 that were in different regions of the US with very low COVID-19 cases
1269 (Montgomery County, MD), very high COVID-19 cases (Knox County, TN), and a county
1270 with cases in between the two (Suffolk County, MA). In this analysis, we estimated that a
1271 typical gathering will last 5 hours and can be held both indoors or outdoors. The indoor scenario
1272 is considered to take place in a room (i.e. 30ft x 30ft x 9ft or 9.14m x 9.14m x 2.74m). We
1273 utilized the COVID ActNow tracker (U.S. COVID Risk & Vaccine Tracker) to determine the
1274 latest number of cases and vaccination rates on 1/31/2022. In addition, we utilized CDC's
1275 Nationwide Commercial Laboratory Seroprevalence Survey (U.S. COVID Risk & Vaccine
1276 Tracker) to determine the current population recovered from COVID-19, and CDC's Variant
1277 Proportions Tracker (U.S. COVID Risk & Vaccine Tracker) to determine the estimated
1278 percentage of existing SARS-CoV-2 variants that exist in the infected population in each
1279 region. At the time of analysis for all counties the Omicron variant accounts for >99% of
1280 COVID-19 cases (U.S. COVID Risk & Vaccine Tracker). It is estimated that the Omicron
1281 variant is 440% more transmissible than the original SARS-CoV-2 reference strain (Araf et al.
1282 2022). We analyzed for the following different parameters to account for multiple different
1283 scenarios that gatherings can take place: distancing ranging from 1.5ft to 10ft, masks usage
1284 (i.e. no masks, average masks, and N95/KN95 masks), and if the group of people are either
1285 "following all public health guidance" or "equal to the community average". In addition, we
1286 also considered testing to be included with one of the scenarios. All data was recorded in
1287 Microsoft Excel 2019 and all data analyses were completed using R version 4.0.3, RStudio
1288 version 1.4.1717, and ggplot2 v3.3.5 (Wickham 2016).

1289

1290 **NASA Ames Research Center CEAT Tool Usage**

1291 In initial assessments, utilizing CEAT V B.6 that was released on November 25, 2020 Step
1292 1 ("The group is composed of people who...") was generally selected as "You think are
1293 following all public health guidance". Step 2 ("Number of People Sharing Activity Space")
1294 was set to the requested number of personnel required to conduct the operation in-person. In
1295 general this was 2 to 4 people per location per operation. Selected distance (Step 3) was set to
1296 6 feet ("-6 distancing adjustment") unless specified otherwise. For Mask Efficacy (Step 4)
1297 "cloth masks" worn by all personnel were selected as cloth was the most likely utilized (-5 and

1298 -3, respectively). Very few projects were using surgical masks and masks were required to be
1299 worn by everyone on campus at this time. Vocalization (Step 5) and breathing (Step 6)
1300 adjustment rates, as well as Duration of Activity (Step 7) were based on the operations reported
1301 in the RTOW plan submission. Typical operations are conducted while “standing”, “speaking”,
1302 and “passive” (0 and 0) for 8 hours. Ventilation rates (Step 8) and Adjustment for room sizes
1303 (Step 9) were based on location of the operation reported in the RTOW plan submission. Step
1304 10 (“Calculate Adjustment to Local Community’s Current Conditions”) was based on the State
1305 of California (US State of California 2022a). The California case rate was chosen instead of
1306 the local county case rate as the majority of the NASA ARC workforce resides in the general
1307 Bay Area which encompasses nine counties, some of which have weekly case rates more
1308 similar to California than to the local county. After inputting these desired values for the
1309 variables in Steps 1-10, the relative exposure ratio for a given condition was recorded and
1310 analyzed in Microsoft Excel 365.

1311 CEAT V B.14 was released on December 13, 2020 the inputs were similar to that of V B.6,
1312 the difference being that for Step 9 actual room dimensions could be entered.

1313 CEAT V B.29 was released on May 6, 2021 Step 1 (“The group is composed of people
1314 who...”) was selected as “Are following all public health guidance”. However, since the
1315 percent vaccination rate was unknown, it was not checked. Step 2 (“Number of People Sharing
1316 Activity Space”) was set to the requested number of personnel required to conduct the operation
1317 in-person. In general this was 2 to 4 people per location per operation. Selected distance (Step
1318 3) was set to 6 feet unless specified otherwise. For “Mask Type and Prevalence” (Step 4) “cloth
1319 masks” worn by all personnel were selected as cloth was the most likely utilized. Very few
1320 projects were using surgical masks and masks were required to be worn by everyone on campus
1321 for all but a 6 week window where masks were optional for vaccinated personnel. Vocalization
1322 (Step 5) and breathing (Step 6) adjustment rates, as well as Duration of Activity (Step 7) were
1323 based on the operations reported in the RTOW plan submission. Typical operations are
1324 conducted while “standing”, “speaking”, and “passive” for 8 hours. Ventilation rates (Step 8)
1325 and Adjustment for room sizes (Step 9) were based on location of the operation reported in the
1326 RTOW plan submission. Step 10 (“Calculate Adjustment to Local Community’s Current
1327 Conditions”) was based on the State of California (US State of California 2022a), (US State of
1328 California 2022b) and variant information was input from CDC data (CDC 2020c). When
1329 variant prevalence was introduced into the CEAT in later iterations, the three most prevalent
1330 variants in Health and Human Services (HHS) Region 9 were used (CDC 2020c). Specifically,
1331 the variant prevalence data from Nowcast was utilized. Instead of utilizing the predetermined

1332 variants provided in the CEAT, NASA ARC input data from the three most prevalent variants
1333 in the HHS Region 9. The “Protection Effectiveness of Immunity (%)” in Step 10 was set to
1334 66% based on published research regarding the Pfizer-BioNTech, Moderna, and Janssen
1335 vaccine against the Delta variant (Fowlkes 2021). After inputting these desired values for the
1336 variables in Steps 1-10, the relative exposure ratio for a given condition was recorded and
1337 analyzed in Microsoft Excel 365. Although CEAT V B.32 was released on August 29, 2021 it
1338 was not used in this analysis. To generate a graphical representation of the data (**Fig. 4**) we
1339 associated numerical values to the different parameters in the table and utilized R version 4.03,
1340 RStudio version 1.4.1717 with the following R packages: ggplot2 v3.3.5 (Wickham 2016).

1341 For the longitudinal review of the NASA ARC “Centerwide Accepted Median Exposure
1342 Risk Ratio” in relation to the community case rates CEAT V B.6, V B.14, and V B.29 were
1343 utilized, this was dependent on the newest version available. Initial inputs at the time of the
1344 RTOW plan were utilized and Step 10 (“Calculate Adjustment to Local Community’s Current
1345 Conditions”) rates were updated on a biweekly basis based on the State of California (US State
1346 of California 2022a). The median of all project exposure risk ratios was used instead of the
1347 average to account for the high fluctuations in exposure risk ratios. Hypothetical exposure risk
1348 ratios were back-calculated to March 2020. Only projects that had been approved to RTOW,
1349 along with projects that were deemed mission essential and were exempt from the work from
1350 home policy (e.g. Security Guards, Security Operations Center) were included in the calculated
1351 biweekly median risk ratio. The relative exposure ratio for a given condition was recorded, the
1352 median exposure ratio was calculated biweekly, and the correlation coefficient compared to the
1353 community case rates was calculated in Microsoft Excel 365. The median of all project
1354 exposure risk ratios was used instead of the average to account for the high fluctuations.
1355 Although the CEAT was not used at NASA ARC until December 2020, hypothetical exposure
1356 risk ratios were back-calculated to March 2020, when NASA ARC enacted their mandatory
1357 work from home policy, for each project using the known historic California case rates. Only
1358 projects that had been approved to RTOW, along with projects that were deemed mission
1359 essential and were exempt from the work from home policy (e.g. Security Guards, Security
1360 Operations Center) were included in the calculated biweekly median exposure risk ratio. A plot
1361 was generated for this data (**Fig. 5**) using R version 4.0.3, RStudio version 1.4.1717 with the
1362 following R packages: ggplot2 v3.3.5 (Wickham 2016).

SARS-CoV-2 transmits person-to-person when an infected person sheds the virus.

Determine risk exposure to COVID-19 with COVID-19 Exposure Assessment Tool (CEAT)

CEAT model was demonstrated to be accurate predicting infection rates for known transmission events.

Example of how to use CEAT to properly determine lowest risk to COVID-19 exposure for gatherings

Parameters to adjust in CEAT

Results from CEAT can determine optimal safest gathering

CEAT Model outperformed the current transmission model used to determine SARS-CoV-2 exposure risk (i.e. Wells-Riley Model)

Real time usage of CEAT to manage potential risk posed by SARS-CoV-2 exposures: Usage by NASA Ames Research Center (ARC) health and safety professionals

NASA ARC used CEAT to determine lowest COVID-19 exposure in different work scenarios

A)

Start Step 1 Enter information that describes the group.

a. Group's Infection Likelihood compared to the Community

The Group is composed of people who, prior to this activity, you estimate have a likelihood of COVID-19 infection that is:

10x lower than the community's average due to their adhering to public health guidance on distancing, masking, and exposure to crowds/people.	<input type="checkbox"/>	<input type="checkbox"/>
10x lower than the community's average due to their adhering to public health guidance on distancing, masking, and exposure to crowds/people. Equal to the community average.	<input type="checkbox"/>	<input type="checkbox"/>
10x higher than the community's average due to their not adhering to public health guidance on distancing, masking, and exposure to crowds. 100 percent, since they are known to be diagnosed with active COVID-19.	<input type="checkbox"/>	<input type="checkbox"/>

b. Group's Vaccination Rate: 100.00 % Click to apply Group's Vaccination Rate to the Exposure Calculations

c. Group members use of viral genome or protein surveillance testing

All members are tested within 3 days prior to event All unvaccinated members are tested within 3 days prior to event (or testing status unknown) Testing not required

Step 2 Enter the number of people sharing the space for the activity. Must be between 2 and 250 people.

Number of People: **A** 2 **B** 2

Sharing Activity Space: **A** 2 **B** 2

Step 3 Enter distance (Option 1) or select distance (Option 2)

Option 1: **A** 3.00 **B** 3.00

Option 2: 1m 2m 3m 4m 5m 6m 7m 8m 9m 10m

Step 4 Select Mask Type and Prevalence of mask wearing

Filter Type: **A** **B**

Fitted N95	<input type="checkbox"/>	<input type="checkbox"/>
N95/N99	<input type="checkbox"/>	<input type="checkbox"/>
Double Surgical Mask	<input type="checkbox"/>	<input type="checkbox"/>
Surgical Mask	<input type="checkbox"/>	<input type="checkbox"/>
Average Mask	<input type="checkbox"/>	<input type="checkbox"/>
Cloth Mask	<input type="checkbox"/>	<input type="checkbox"/>
No Mask	<input type="checkbox"/>	<input type="checkbox"/>

% of People Wearing Masks: 0% to 100%

Step 5 Select Vocalization Intensity **Step 6** Select Breathing Rate

Activity	Exhalation Type	A	B
Resting	Silent	<input type="checkbox"/>	<input type="checkbox"/>
	Speaking	<input type="checkbox"/>	<input type="checkbox"/>
	Loudly speaking	<input type="checkbox"/>	<input type="checkbox"/>
Standing	Silent	<input type="checkbox"/>	<input type="checkbox"/>
	Speaking	<input type="checkbox"/>	<input type="checkbox"/>
	Loudly speaking	<input type="checkbox"/>	<input type="checkbox"/>
Light exercise	Singing	<input type="checkbox"/>	<input type="checkbox"/>
	Speaking	<input type="checkbox"/>	<input type="checkbox"/>
	Loudly speaking	<input type="checkbox"/>	<input type="checkbox"/>
Heavy exercise	Silent	<input type="checkbox"/>	<input type="checkbox"/>
	Speaking	<input type="checkbox"/>	<input type="checkbox"/>
	Loudly speaking	<input type="checkbox"/>	<input type="checkbox"/>

Activity	A	B
Sleep	<input type="checkbox"/>	<input type="checkbox"/>
Resting	<input type="checkbox"/>	<input type="checkbox"/>
Passive/Light Activity	<input type="checkbox"/>	<input type="checkbox"/>
Moderate Exertion	<input type="checkbox"/>	<input type="checkbox"/>
Heavy Exertion	<input type="checkbox"/>	<input type="checkbox"/>

Step 7 Enter the duration that most closely matches the activity.

Duration of Activity in Hours: **A** 0.25 **B** 0.25

Step 8 Select whether outdoor or indoor

a. Outdoor: A: B: Outdoor activities: Select wind conditions that best match.

		Beaufort Scale		A	B
Moderate	21 - 29 km/h	Raises dust and loose paper, small branches are moved	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Gentle	15 - 19 km/h	Leaves/small twigs in constant motion, wind extends light flag	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Light	8 - 13 km/h	Wind felt on face, leaves rustle	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Calm	2 - 5 km/h	Direction of wind shown by smoke drift	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Very Calm	0.8 - 1.3 km/h	No direction or flow observed	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

b. Indoor: A: B:

Obtain the Air Changes per Hour (ACH) using Option 1 or 2:

Option 1 - Use ACH provided by building engineers or H&S.

Option 2 - from Table 1 on right, select the facility type and ACH that best matches the activity location.

Table 1: Typical ACH Values (Option 2)

Facility Type	ACH
General	6
Laboratory	6
Treatment room	6
Classroom/room	6
Retail	1.5
Sales (except as below)	1.5
Hair and nail salons	1.75
Department	1
Fast food	6
Bar	2.4
Restaurants	1.4
Education	
Classrooms (ages 5 to 16)	2
Classrooms (age 9 plus)	2
Classroom (through age 12)	2.5
Multiple assembly	5
Lecture (closed doors)	7
Lecture (open doors)	3
Lecture (closed)	3
Libraries	1.5
Music/Choir/dance	1.5
Office	
Office space	0.5
Reception Area	1.25
Meeting/Conference Rooms	2
Manufacturing	
Manufacturing floor	1.5
Residential	
Homes with closed windows	0.5
Rooms with one open window	1.75
Homes with all open windows	3
Travel	
Aircraft	20
Trains/Buses	6
Cars (Windows Closed)	6
Cars (Windows Open)	10

Enter indoor ACH (or AER) Values:

Indoor ACH: **A** 6.00 **B** 6.00

¹ ACH (Air Changes per Hour) is synonymous with AER (Air Exchange Rate (Exchanges/Hours))

c. Room Filtration

Select Flowrate Option:

Flow Option 1 - Use a default assumption of flow of filtered air of 5 L/sec/m².

Flow Option 2 - Enter a specific filtration flow rate if known

Flowrate (L/sec): 0

HEPA Filters	<input type="checkbox"/>	<input type="checkbox"/>
MERV 13	<input type="checkbox"/>	<input type="checkbox"/>
MERV 8	<input type="checkbox"/>	<input type="checkbox"/>
No Filters	<input type="checkbox"/>	<input type="checkbox"/>

Step 9 If indoors, enter the room dimensions and the height of the ceiling.

Room Length (m): **A** 2.8 **B** 2.8

Room Width (m): **A** 2.8 **B** 2.8

Ceiling Height (m): **A** 3.00 **B** 3.00

Room Area (m²): **A** 8.0656 **B** 8.0656

Room Volume (m³): **A** 24.196 **B** 24.196

Important: CEAT must be opened with Adobe Acrobat® or Adobe Reader® to function. See Page 2 for a technical summary and Page 3 for instructions.

Step 10 Calculate Adjustment to Local Community's Current Conditions

Average Daily Cases per 100,000 (in the Last Week): 36.50

Average Days Infectious (Set to 5 if not known): 5.00

Undiagnosed Factor for Area (Set to 3 if not known): 5.0

Active Infections per 100,000: 909.2

Variant Prevalence	Estimate of Portion of Active Infections (%)	Comparative Increased Transmission versus Wild-Type Virus (%)	Immunity Prevalence
WHO Variant Label			Population Vaccination Rate (%)
Alpha	0.00	0.00	Population Recovered (%)
Beta	0.00	0.00	Protection Effectiveness of Immunity (%)
Delta	0.00	100.00	Correlation Factor
Omicron	0.00	940.00	Poison Distribution Adjustment Factor

Result:

Group-wide Exposure Ratio

Exposure Ratio	Lower Exposure	Medium	High	Very High
A	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
B	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Group-wide Exposure Ratio	A	B
Group-wide Exposure Ratio:	0.58190e	0.58190e
Near Field:	0.38502e	0.19688e
Far Field:	0.38502e	0.19688e
Individual (Indv.) Exposure Ratio:	0.58190e	0.58190e
Indv. Dose (Quanta):	0.0256	4.191e
Infect Rate:	1	4.191e
# of Index Infections:	1	1

END Take actions to reduce exposure!

HIGH OR VERY HIGH: Make changes to reduce exposure. Rethink the event or activity. Combine multiple mitigations such as using N95 masks, increasing ventilation, holding event outside, greatly increasing distancing, reducing people, or shortening the duration

Disclaimer Statement:

By using this tool you agree to be bound by this disclaimer. B)

1 Comparative Group-wide Dose Equation and Corresponding CEAT Model Steps

RESULT:	Step 1:	Step 10:	Step 5:	Step 2:	Step 3:	Step 8:	Step 9:	Step 7:	Step 4a:	Step 4b:	Step 6:	Step 2:	Step 7:	Step 10:	Step 1:
Group-wide Dose Ratio	Behavior of Sub Population	Local Epidemiology	Emission of Virus	# of People	Distancing	Ventilation Rate	Indoor Dim.	Duration	Mask Effectiveness on Exhalation	Mask Effectiveness on Inhalation	Inhalation Rate	# of People	Duration	Local Epidemiology Factors	Behavior of Sub Population

$$\frac{\bar{D}_{Quanta\ i}}{\bar{D}_{Quanta\ BL}} = \frac{\varphi_i}{\varphi_{BL}} \times \frac{\dot{M}_i}{\dot{M}_{BL}} \times \frac{P_{e\ emitting\ i}}{P_{e\ emitting\ BL}} \times \frac{\sum_{i=1}^{Pe-1} (FF_{Factor\ i} + NF_{Factor\ i})}{\sum_{i=1}^{Pe-1} (FF_{Factor\ BL} + NF_{Factor\ BL})} \times \frac{(1 - E_{f\ out\ i})}{(1 - E_{f\ out\ BL})} \times \frac{(1 - E_{f\ in\ i})}{(1 - E_{f\ in\ BL})} \times \frac{Q_{in\ hale\ i}}{Q_{in\ hale\ BL}} \times \frac{P_{e\ total\ i}}{P_{e\ total\ BL}} \times \frac{\Delta t_i}{\Delta t_{BL}} \times \frac{V_{ariant\ Adj\ i}}{V_{ariant\ Adj\ BL}} \times \frac{I_{mmunity\ Adj\ i}}{I_{mmunity\ Adj\ BL}} \times \frac{T_{est\ Adj\ i}}{T_{est\ Adj\ BL}}$$

\bar{D}_{mass}	φ	\dot{M}	$P_{e\ emitting}$	FF_{Factor}	NF_{Factor}	$E_{f\ out}$	$E_{f\ in}$	$Q_{in\ hale}$	$P_{e\ total}$	Δt	$V_{ariant\ Adj}$	$I_{mmunity\ Adj}$	$T_{est\ Adj}$	BL	i
Dose of inhaled contaminant (quanta)	Likelihood that any individual member of the group is infectious at the start of the scenario or modeled event (dimensionless)	Emission rate of contaminant (quanta/hour)	Number of emitting people (i.e., number of potential sources) in the group. (#)	Far Field Factor (m ³ /hour ²)	Far Field Factor (m ³ /hour ²)	Bulk mass efficiency of mask during exhalation for contaminant (dimensionless)	Bulk mass efficiency of mask during inhalation for contaminant (dimensionless)	Inhalation Rate (m ³ /hour)	Total number of people in the group (#)	Duration of exposure (hour)	Adjustment for higher transmission rate of variants as compared to wild type virus (dimensionless)	Adjustment for the rate of immunity and efficacy of immunity among the community or group (dimensionless)	Adjustment for the efficacy of test regimes used for a group (dimensionless)	Indicates baseline variable	Indicates value for the evaluated scenario

2 Individual Dose Ratio

$$\frac{\bar{D}_{Quanta\ i}}{\bar{D}_{Quanta\ BL}} = \frac{\varphi_i}{\varphi_{BL}} \times \frac{\dot{M}_i}{\dot{M}_{BL}} \times \frac{\sum_{i=1}^{Pe-1} (FF_{Factor\ i} + NF_{Factor\ i})}{\sum_{i=1}^{Pe-1} (FF_{Factor\ BL} + NF_{Factor\ BL})} \times \frac{(1 - E_{f\ out\ i})}{(1 - E_{f\ out\ BL})} \times \frac{(1 - E_{f\ in\ i})}{(1 - E_{f\ in\ BL})} \times \frac{Q_{in\ hale\ i}}{Q_{in\ hale\ BL}} \times \frac{\Delta t_i}{\Delta t_{BL}} \times \frac{V_{ariant\ Adj\ i}}{V_{ariant\ Adj\ BL}} \times \frac{I_{mmunity\ Adj\ i}}{I_{mmunity\ Adj\ BL}} \times \frac{T_{est\ Adj\ i}}{T_{est\ Adj\ BL}} \quad (Eq. 4)$$

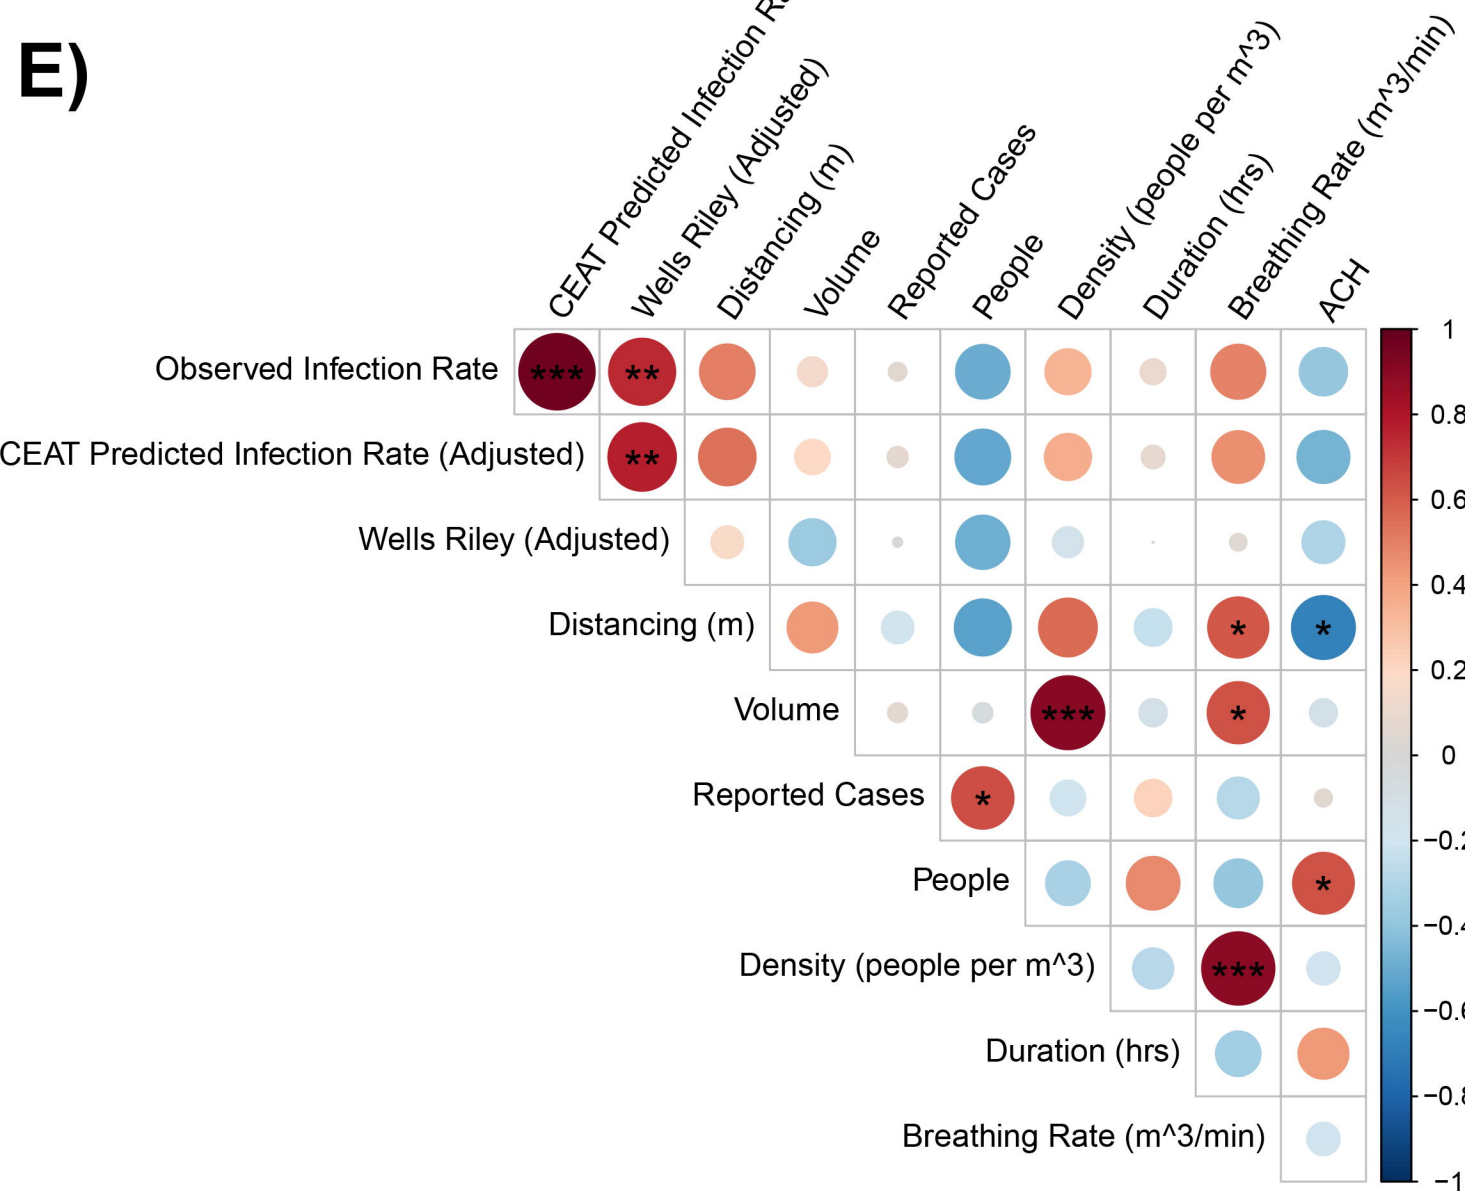

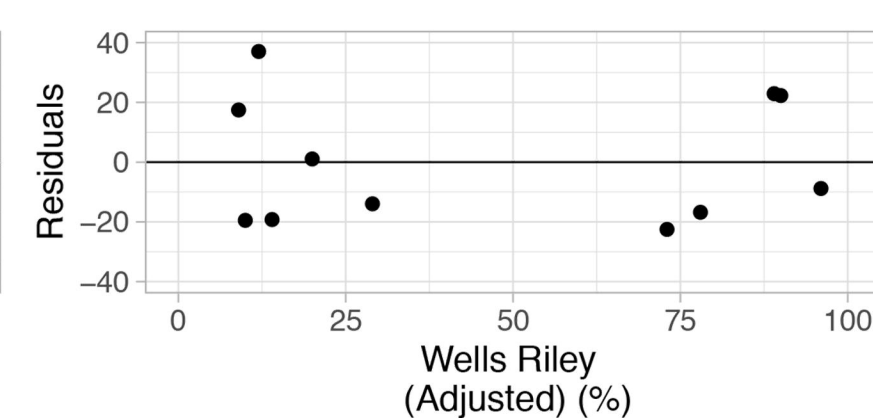

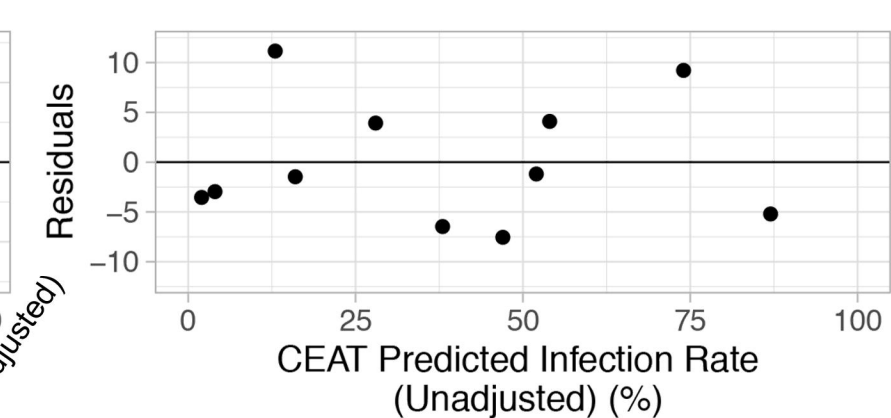

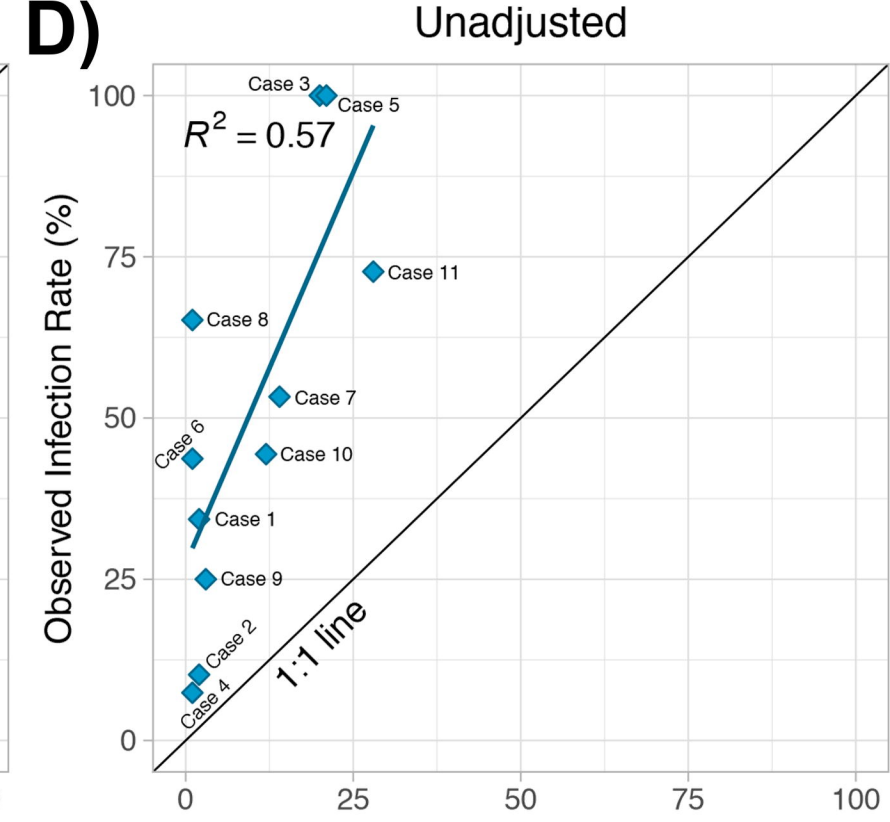

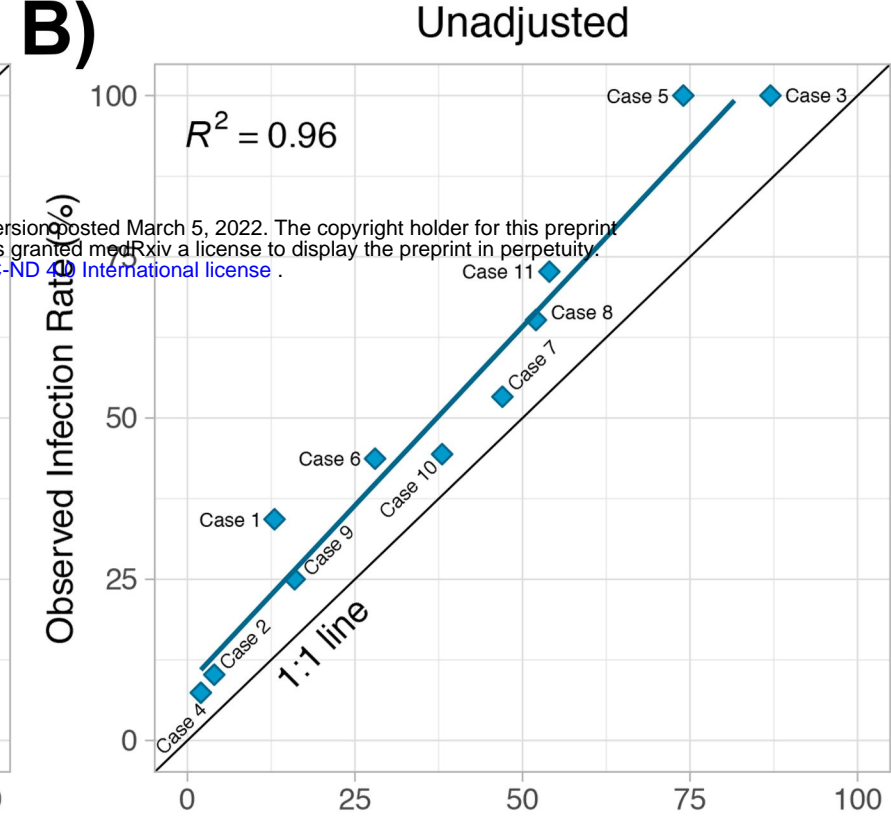

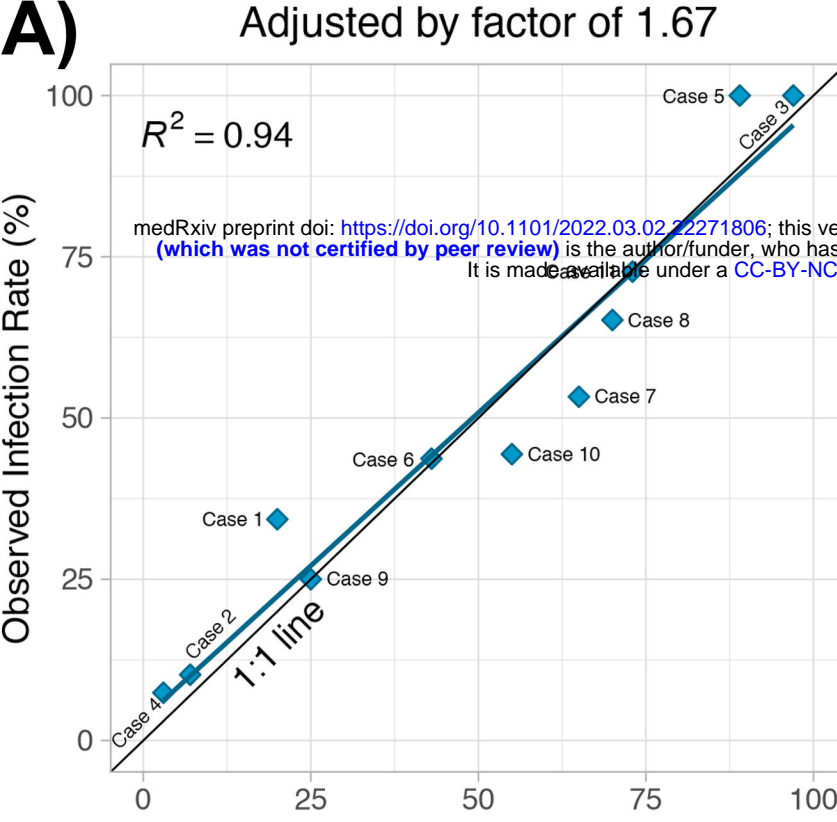

3 Individual Dose

$$\bar{D}_{Quanta\ i} = \varphi_i \times \dot{M}_i \times \sum_{i=1}^{Pe-1} (FF_{Factor\ i} + NF_{Factor\ i}) \times (1 - E_{f\ out\ i}) \times (1 - E_{f\ in\ i}) \times Q_{in\ hale\ i} \times \Delta t_i \times V_{ariant\ Adj\ i} \times I_{mmunity\ Adj\ i} \times T_{est\ Adj\ i} \quad (Eq. 5)$$

4 Individual Dose with One Index Case, No Masking (before variant emergence, vaccination, and use test protocols)

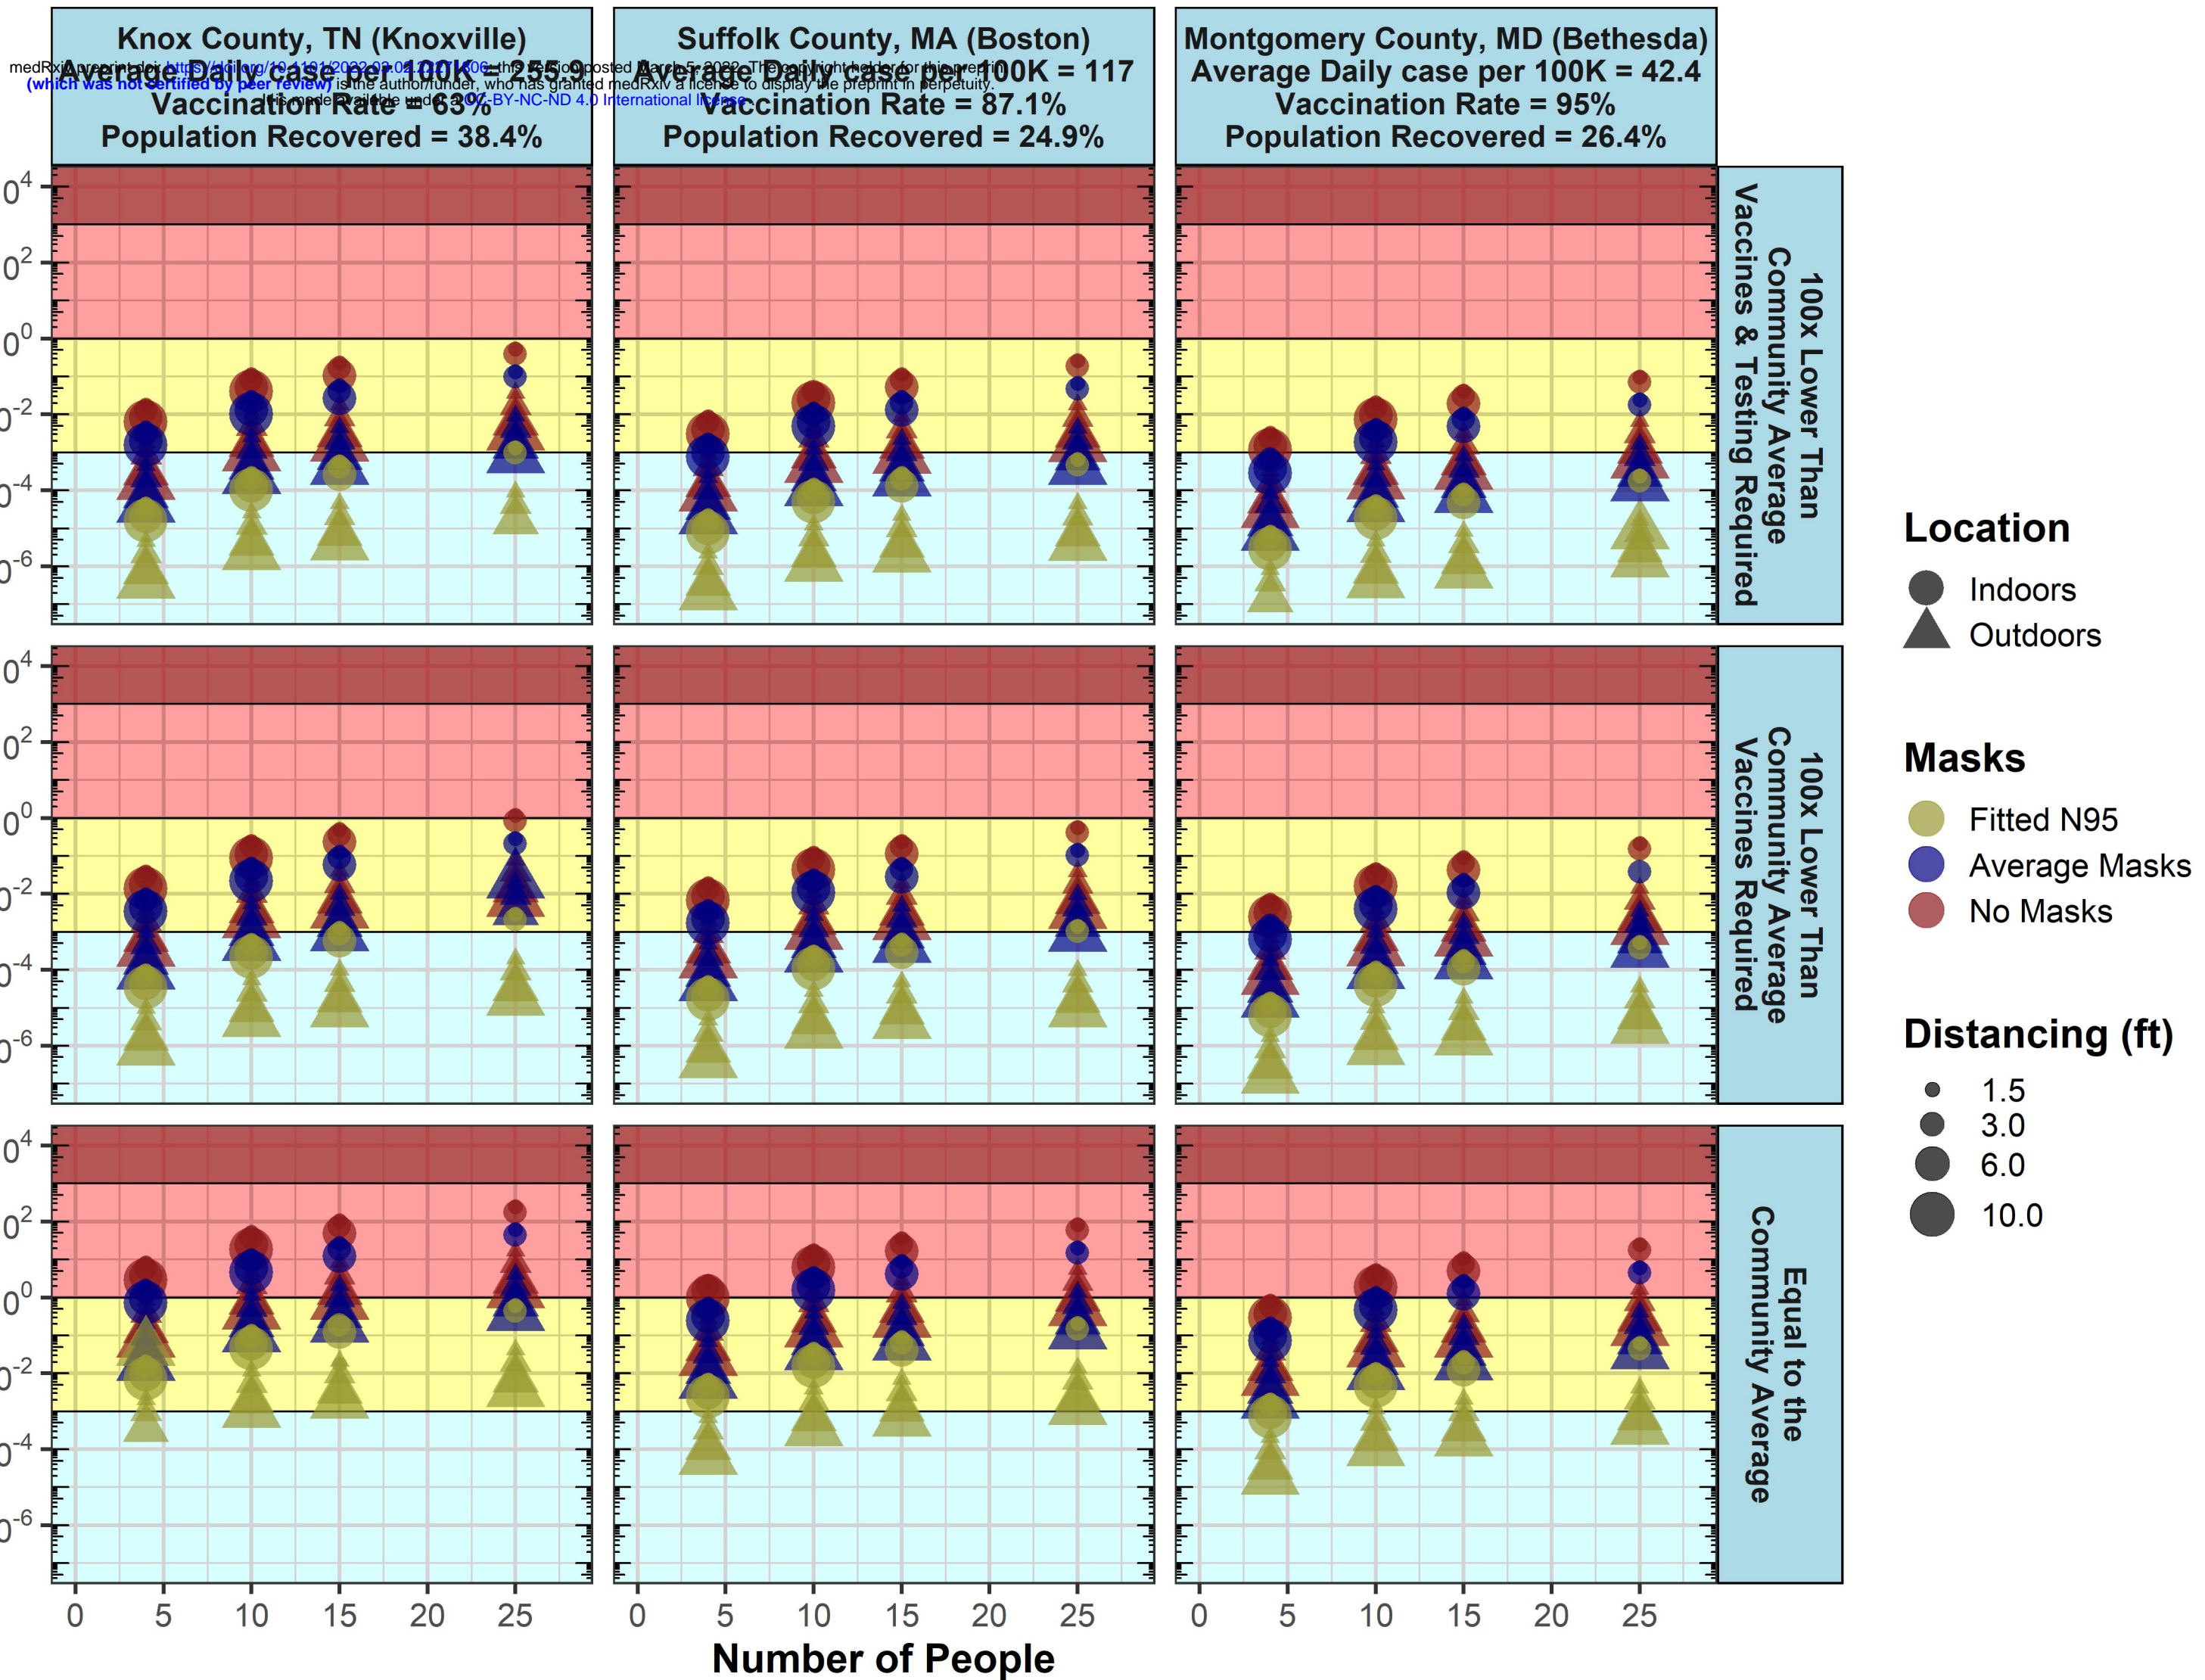

$$\bar{D}_{Quanta\ i} = \varphi_i \times \dot{M}_i \times \sum_{i=1}^{Pe-1} (FF_{Factor\ i} + NF_{Factor\ i}) \times Q_{in\ hale\ i} \times \Delta t_i \quad (Eq. 6)$$

$\varphi_i = 1 / (P_{e\ total\ i} - 1)$

COVID-19 Exposure Assessment for Gatherings of 5 hours

Very High Risk, High Risk, Medium Risk, Low Risk

NASA Ames Research Center Accepted Exposure Risk in Relation to Community Case Rates

medRxiv preprint doi: <https://doi.org/10.1101/2022.03.02.22271806>; this version posted March 5, 2022. Factors considered in Exposure Dose Calculation	Factor Type	CEAT Step #	Basis and/or Range of Values used in CEAT
Likelihood of Infectious persons present in the group	Stochastic	1	Ranges over 5 orders of magnitude from the lowest (0.0001%) assumed for people adhering strictly to public health guidance, to the highest (100%) for those known to be infected.
Number of people in the group	Mechanistic/ Stochastic	2	Ranges from 2 to 250 people.
Distance between people	Mechanistic	3	Users are given discrete options: 4.5 m (~15 ft), 3 m (~10 ft), 2 m (~6ft), 1 m (~3 ft), and 0.5 m (~1.5 ft).
Mask effectiveness	Mechanistic	4	Range of mask effectiveness values based on published data for cloth, surgical, and N-95 masks. (CDC, 2020) (Mueller et al., 2020)
Mask compliance on the group	Stochastic	4	Ranges between 0 and 100 percent.
Emission rate of Infectious aerosols released through respiration	Mechanistic	5	Range of viral RNA emissions rates by activity in viral quanta per hour (Buonanno, et al., August 2020) (Buonanno et al., December 2020)
Inhalation rate	Mechanistic	6	Typical inhalation rates for adults at various activity intensities (US EPA, 2015)
Duration of exposure	Mechanistic	7	Varies between 5 minutes and 12 hours
Indoors or outdoors activity	Mechanistic	8	Indoor or Outdoor options affect the form of the concentration model used.
Ventilation rates (air changes per hour [ACH] or air exchange rate [AER])	Mechanistic	8	(Values based on published sources (CDC, 2019) (ANSI/ASHRAE Standard 62.1-2019, 2020) (Howard-Reed et al., 2002)
Aerosol settling rate	Mechanistic	8	Removal by deposition on surfaces (CIRES, 2020)
Virus degradation rate	Mechanistic	8	An ACH contribution from viral aerosol degradation (CIRES, 2020)
Recirculating room filtration rate and removal efficiency	Mechanistic	8	Recirculation of filtered air assumed to occur at a rate of 5 [L/s]/m ² (1 cfm/ft ²) (ANSI/ASHRAE Standard 62.1-2019, 2020)

Volume of room or activity space	Mechanistic	9	Varies based on user-specified dimensions, with constraints based on number of people and specified distancing. Ceiling height ranges between 2.15 meters (7 feet) and 20 meters (65 feet). Room side dimensions range between 2 meters (7 feet) and 200 meters (650 feet).
Prevalence of COVID-19 in the community	Epidemiological /Stochastic	10	Active cases per 100,000 is estimated by the published "Average Daily Cases per 100,000 in the Last Week" available from various sources and estimates of the "Average Days Infectious" and "Undiagnosed Factor." (REF)
Difference in the variants transmission rates versus wild type virus	Epidemiological	10	Users can adjust the equivalent exposure dose upward by a factor proportional to the reported increased variant transmission.
Impact of community's or group's immunity from recovery and vaccination	Epidemiological	1 and 10	Immunities are addressed in two ways: 1) Reduced shedding (3x reduction is used) (Levine-Tiefenbrun, et al., 2021); 2) User can enter value vaccine efficacy (from Graniss, et al., 2021 and Scobie, et al., 2021) to function as "effective immunity barrier" at a level consistent with its
Impact of surveillance testing for the group	Epidemiological	1	Estimate (Need to come up with a reference for this)

Table 1. Summary of Factors considered in CEAT. Mechanistic, stochastic, epidemiological factors are accounted for the model exposure and inhalation dose

Case Number	Event Description	Volume of Room or Facility (m³)	People at Event	Total Cases Attributed to the event (Secondary Cases)	Total Infected Total Susceptible	Primary Reference
Case 1	Bus, Zhejiang Province, China, 19 Jan 2020	80.0	68	23	34%	Shen, et al., 2020
Case 2	Restaurant, Guangzhou, China, 24 Jan 2020	480.4	89	9	10%	Li, et al., 2021
Case 3	Meeting, Munich, Germany, 21 February 2020	210.0	13	12	100%	Hijnen, et al., 2020
Case 4	Commercial Aircraft, Flight VN54 (London, UK - Hanoi, Vietnam), 1 March 2020	662.2	217	16	7%	Khanh, et al. 2020
Case 5	Recreational Squash Game, Maribor, Slovenia, 4 March 2020	458.5	2	1	100%	Brek, et al., 2020
Case 6	Call Center, South Korea, 8 March 2020	3267.0	216	94	44%	Park, et al., 2020
Case 7	Choir Rehearsal, Skagit Valley, WA, USA, 10 March 2020	808.0	61	32	53%	Miller, et al., 2021
Case 8	Recreational Hockey, Tampa Bay, Florida USA 16 June 2020	14452.7	24	15	65%	Atrubin, et al. 2020
Case 9	Restaurant, Jeonju, South Korea, 17 June 2020	184.8	13	3	25%	Kwon, et al, 2020
Case 10	Court Room, Vaud, Switzerland,	149.5	10	4	44%	Vernez, et al., 2021

	30 Sep 2020					
Case 11 (Omicron)	Holiday Party, Oslo, Norway, 30 Nov 2021	1062.7	111	80	72%	Norwegian Institute of Public Health, 2021

Table 2. Reported COVID-19 transmission events.
