20 ABSTRACT

21 We studied a unique case of prolonged viral shedding in an immunocompromised patient 22 that generated a series of SARS-CoV-2 immune escape mutations over a period of seven 23 months. During the persisting SARS-CoV-2 infection seventeen non-synonymous mutations 24 were observed, thirteen (13/17; 76.5%) of which occurred in the genomic region coding for 25 spike. Fifteen (15/17; 88.2%) of these mutations have already been described in the context 26 of variants of concern and include the prominent immune escape mutations S:E484K, 27 S:D950N, S:P681H, S:N501Y, S:del(9), N:S235F and S:H655Y. Fifty percent of all mutations acquired by the investigated strain (11/22) are found in similar form in the Omicron variant of 28 29 concern. The study shows the chronology of the evolution of intra-host mutations, which can 30 be seen as the straight mutational response of the virus to specific antibodies and should 31 therefore be given special attention in the rating of immune escape mutations of SARS-CoV-32 2.

33

34 INTRODUCTION

35 In December 2019 the Wuhan Municipial Health Commission (China) reported a cluster of 36 cases of pneumonia of unknown etiology to the WHO China Country Office. By the beginning 37 of 2020 it was confirmed that a novel coronavirus later named severe acute respiratory 38 syndrome coronavirus (SARS-CoV-2), was the causative agent (1). SARS-CoV-2 spreads 39 easily and effectively among human beings with a basic reproduction number (R0) of > 2 (2, 40 3). Following this rapid human-to-human transmission and intercontinental spread the WHO declared a global pandemic in March of 2020. The first cases in Austria were reported in 41 42 Ischgl, Tyrol, as early as February 2020 - and East Tyrol was considered one of the first 43 hotspot areas in Central Europe.

44 While mutations are common in RNA viruses and mostly will not make a significant 45 difference, some mutations proved to provide SARS-CoV-2 with a selective advantage, such 46 as increased transmissibility or increased escape from specific antibodies (4-8). Those

variants with proven or suspected immune escape mutations were deemed variants of
concern (VOC) or variants of interest (VOI), respectively, and require close monitoring
(https://www.who.int/en/activities/tracking-SARS-CoV-2-variants/). The spread of the first
described variant of concern (Alpha variant, B.1.1.7, VOC) was confirmed early in Austria
and increased from 0.7% in January to > 99% in April 2021 in the study area East Tyrol
(https://www.ages.at/themen/krankheitserreger/coronavirus/sars-cov-2-varianten-in-

53 oesterreich/). As of December 2020, the European Center for Disease prevention and control 54 (ECDC) noticed a sharp decline of the Alpha variant in the European Union (EU; 14.5%) 55 followed by a fast spread of the Delta (B.1.617.2) in spring, 2021, plus a few shares of the 56 Gamma (P1 or B.1.1.28.1, 0.3%) and others virus variants (0.3%). By January 2022, these 57 variants have been largely replaced by the Omicron variant (B.1.1.529) in the study area. 58 The Omicron variant now accounts for > 95% of cases. Common in these successful variants 59 are a few specific genomic changes that give them a decisive benefit in terms of 60 transmission or replication, e.g. in the pharynx. The most prominent spike substitutions with 61 immune escape effect can be found in several VOC or VOI. For example, N501Y in the 62 Alpha, Beta and Omicron variant, a nucleotide exchange at position E484 to K in the Alpha-63 (in a subvariant), Beta and Gamma, to Q in a Delta subvariant or to A in both Omicron 64 subvariants BA.1 and BA.2. Furthermore, P681H is found in the Alpha and Omicron variant 65 as well as in the VOI B.1.1.238 and the spike deletions 144/145 described as recurrent deletion regions, since they multiply occurred (9, 10). 66

67 The origin of immune escape variants is still a matter of speculation. Several hypotheses 68 take zoonotic origin, selective pressure during treatment with antiviral drugs, monoclonal 69 antibodies or convalescent plasma into consideration and a few studies point to the 70 significance of the exceptional intra-host environment of immunocompromised patients to 71 explain the evolution of immune escape variants (11-13). Those cases showed especially 72 long-lasting viable viral shedding of SARS-CoV-2 in immunosuppressed patients for a period 73 of more than four months (11-13). Two of the patients treated with monoclonal and 74 convalescent plasma showed unusually high numbers of nucleotide changes and deletion 75 mutations (12, 13), among others the already described immune escape mutation S:del69/70 76 (13).

77 In November 2020 we became aware of a patient in her 60ies with lymphoma who showed 78 persistingly high pharyngeal viral loads of SARS-CoV-2. Although the patient had detectable 79 SARS-CoV-2 specific antibody responses, she was unable to clear the virus load. Therefore, 80 close monitoring was performed by rtPCR of naso-pharyngeal swabs. This unusual case 81 prompted us to perform a thorough sequential serological screening as well as investigation 82 of virus mutant development. Viral titre and mutant development of SARS-CoV-2 was 83 monitored by regular naso-pharyngeal swabs with subsequent rtPCR and Next-Generation 84 Sequencing (NGS), which enabled us to monitor the chronology of the evolution of immune 85 escape mutations. We discuss these findings in the light of potential new sources of intra-86 host escape mutations and with respect to adaptations of the vaccination strategy.

87

88 METHODSRESULTS

89 <u>Clinical presentation of an immunocompromised individual persistently infected with</u> 90 <u>SARS-CoV-2</u>

91 In August 2015, the patient was diagnosed with stage IVa small cell lymphocytic lymphoma, 92 complicated by a temporary reactivation of Epstein-Barr virus (EBV) with reactive 93 splenomegaly and rapid nodal progression. From June 2016, she was given six cycles of 94 Rituximab and Bendamustine, which led to remission. In October 2019, the patient suffered a 95 relapse with washout and 90% bone marrow infiltration (B-CLL Binet B or RAI III), 96 accompanied by pronounced B symptoms and antibody deficiency. Beginning in May 2020, 97 another round of therapy with Rituximab and Bendamustine was administered. It was 98 completed in November 2020 after six cycles. The leukocytes counted 4200/µL in the lower 99 normal range, platelets 136,000/µL, the immunoglobulins were clearly reduced (IgG 249 100 mg/dL, IgA 3 mg/dL, IgM 12 mg/dL).

101 Four days after the last chemotherapy – mid November 2020 - the patient fell ill with fever, 102 cough, headache and pain, but neither loss of taste nor smell. SARS-CoV-2 was detected in 103 the throat swab by rtPCR. The patient was in guarantine for ten days; a final PCR control 104 was not carried out. Due to persistent fatigue, recurrent fever episodes and persistent cough 105 with little white expectorate, the patient was again admitted to the hospital in the middle of 106 January, 2021 and rtPCR was again positive for SARS-CoV-2. At the same time there was a recurrence of EBV. The patient was enrolled for an inhalation therapy with N-chlorotaurine (3 107 108 times daily inhalation of 10ml of N-chlorotaurine for three minutes and 10 - 14 days) (Nagl et 109 al., 2018; Cegolon et al., 2020) and received 15g intravenous immunoglobuline (IVIG, 110 Intratect®, Biotest Pharma GmbH, Dreieich, Germany) on admission. Ten days later; no 111 specific therapy with antibodies against SARS-CoV-2 having been carried out - the blood 112 findings were unchanged (leukocytes 5500/µL, platelets 102,000/µL (decreased), IgG 301 113 mg/dL, IgA 3 mg/dL, IgM 25 mg/dL), but the leukocyte typing showed a decline by the B-CLL 114 of 70% and a reduction of CD4+ helper T cells. The chest x-ray was normal. The patient 115 suffered from impaired general condition, headache and sore throat and was not able to 116 clear SARS-CoV-2 infection. The patient again received the IVIg therapy (IVIG, Intratect®, 117 Biotest Pharma GmbH, Dreieich, Germany). No antiviral therapeutics were administered to 118 the patient at any time of the infection. An increase of leukocytes was developed (21,600/ μ L).

Since the onset of the symptoms and the first rtPCR positive swab the patient was committed to home quarantine in accordance with Austrian law. When symptoms did not clear after a month, home quarantine was slightly lightened, yet, testing with naso-pharyngeal swabs and subsequent rtPCR was continued. Persistent viral shedding was determined on day 102, day 124, day 182 and day 205 since onset of symptoms and first positive rtPCR and the viral shedding from the upper respiratory tract has continued to date (**Figure 1**). The patient gave full written consent for the case to be attended and published.

126 **Isolation**

lsolation trials were performed from swab samples taken on day 73, 93, 99, 104, 109, 117, 128 127, 133 and 182 on VeroB4-cells and were successful on day 73, 93, 109 and 127. The 129 isolation success correlated negatively with the Ct-values of the swab (k = -0.59).

threshold; IVIG therapy ... intravenous immunoglobuline therapy; RTX ... Rituximab andBendamustine therapy.

137

138 <u>Serology</u>

At the same time points, specific antibodies were investigated using three different serological tools. An overview of the serological results is given in **Table 1**. On day 102 the IgG titres in general and neutralizing antibody titres in particular, were observed in a low degree with an IgG titre of 17.7 AU/mL in CLIA and a borderline titre of neutralizing antibodies of 1:4 in enzyme linked neutralisation assay (ELNA)

Humoral immune responses increased in the course of disease and yielded high values of 145 1320, > 2080 and 1750 AU/mL in chemiluminescent immunoassay (CLIA) and >1:32 in 146 ELNA, on the days 124, 182 and 205, respectively. Although antibodies increased to positive 147 activities at day 124 and were maintained, IgG avidity did not mature over time, as the RAI 148 showed no significant increase and stayed in the low range <20%.

The analysis via immunoblot disclosed Spike 1 (S1) and the dedicated receptor-bindingdomain (RBD) as the main epitopes of the IgG antibodies in the patient's sera, whereas no IgG antibodies could be detected against the region Spike 2 (S2) or the nucleocapsid. No specific IgA antibodies were detected.

Table 1: Evaluation of antibody responses at different time points.

				Activit	
day	CLIA (AU/mL)	ELNA (titre)	Blot IgG (AU/mL)	y (U/mL)	RAI (%)
102	positive (17.7)	borderline (1:4)	negative	1.28	n.d.
124	positive (1320.0) positive	positive (1:32)	positive S1 (209), RBD (405)	106.7	2.9
182	(>2080.0)	positive (>1:32)	positive S1 (294), RBD (459)	145.5	17.4
250	positive (1750.0)	positive (1:32)	positive S1 (229), RBD (353), S2 (85)	69.1.	22.9

Overview of the patient's serological data from day 102, 124 and 182. The used diagnostic 154 tools were the LIAISON® SARS-CoV-2 TrimericS IgG (DiaSorin S.p.A., Saluggia, Italy) 155 156 (LIAISON), an Immunoblot called ViraChip® assay (Viramed, Munich, Germany), Avidity and 157 an in-house Enzyme-Linked Neutralization Assay (ELNA) (Sonnleitner et al., 2021b). The data obtained from LIAISON® SARS-CoV-2 s1/s2 lgG CLIA assay are standardized 158 according to the WHO criteria. CLIA ... chemoluminescent immunoassay; AU/mL ... arbitrary 159 160 units/mL; ELNA ... enzyme-linked immunosorbent assay; S1 ... Spike 1; RBD ... receptor-161 binding-domain; RAI ... relative avidity index (formula: IgG concentration with chaotropic 162 agent/IgG concentration with PBS.

163

164 SARS-CoV-2 specific T-cell response

On day 193 no IFNg-producing SARS-CoV-2-specific immune cells could be detected in the ELISpot assay (SI = 0.86), although a significant positive reaction against pokeweed mitogen was demonstrated (mean of 213 SFU in the positive control versus mean of 1.4 SFU in the negative control and mean 1.2 SFU cells in the SARS-CoV-2-antigen stimulated wells).

169 Humoral immune response did not clear SARS-CoV-2 infection

170 The Ct values and numbers of PFU/mL were significantly lower after day 124. The high titre

of IgG antibodies of 1320 AU/mL and a neutralizing antibody titre of 1:32 analysed by our in-

house assay on day 124 was associated with a significant reduction of the viral load but

173 could not clear the infection.

174 We therefore decided to undertake a detailed examination of the specific genetic background 175 of the virus population present including potential intra-host mutational dynamics.

176 Mutational intra-host dynamics

177 Over the study period of 221 days, 14 haplotypes were sequenced out of naso-pharyngeal 178 samples. The sequences were obtained on day 73, 93, 109, 129, 133, 136, 143, 158, 164, 179 171, 182, 192 and day 207 of the patient's prolonged infection. The timeline of infection and

- 180 a chronology of intra-host non-synonymous mutational events are given in Figure 4.
- 181 The calculation of the pairwise mutation distances did not show higher intra-host evolutionary
- rates in contrast to overall evolutionary rates of about (8-9) x 10⁻⁴ substitutions per year (Day 182 et al., 2020; Dearlove et al., 2020). The pairwise distance between day 73 and day 171 was 183 4.4×10^{-4} in 98 days, implying a nucleotide substitution rate of 7.5 x 10^{-4} . 184
- 185 All NGS sequences were shown to belong to the prevalent Pangolin lineage B.1.1. and the 186 Nextstrain clade 20B.

187 We became aware of the prolonged viral shedding after about two months and started to 188 regularly sequence the patient's subsequent swabs as of day 73. The sequence derived 189 from the swab of day 73 showed 18 mutations in comparison to the reference genome 190 Wuhan (GenBank: MN908947.3, RefSeq: NC_045512.2), the sequence on day 171 had 26 191 substitutions which increased to 29 on day 207. A listing of all persistent and temporary non-192 synonymous mutations that the strain has accumulated intra-host and their concordance to 193 variants of concern and variants of interest are given in Table 2. Overall, 22 non-194 synonymous mutations evolved over the study period of 221 days (7 months). Eleven (50%) 195 of these non-synonymous mutations were persistent, whereas 11 (50%) occurred temporarily 196 and were replaced by the wildtype or a different substitution. Seventeen of the 22 non-197 synonymous mutations evolved in the region coding for spike, eight of those were temporary. 198 Seventeen of the 22 acquired non-synonymous mutations (77.3%) were issued as immune 199 escape mutations by the WHO (https://www.who.int/en/activities/tracking-SARS-CoV-2-200 variants/) (Figure 4). Among the persistent non-synonymous mutations in spike, as many as 201 88.2% are found in various VOIs or VOCs (Table 2). All those genetic changes occurred 202 after the development of high antibody titres.

203 One region continuously showed diffuse mutational changes, with changing temporary 204 adaptations of substitutions and deletions, which was ORF1b: position 709 - 716.

205 An overview of the intra-host mutational development of SARS-CoV-2 during the study 206 period of 221 days is given in Table 3 and Figure 3.

207

Beta variant B.1.351; δ ... 226 Gamma variant B.1.1.28.1; γ ... Delta variant B.1.617.2; o ... Omicron variants B.1.1.529). 227 Underlined mutation sites are also found in the Omicron variant, but with a different 228 substitution.

229

230

Figure 2: Localization of the substitutions and deletions acquired by the strain EPI_ISL_2106199 of clade 20B in the course of the prolonged infection of an immunocompromised patient. All acquired and preserved genetic adaptations occurred in the regions ORF1a (n = 1), ORF1b (n = 1) and spike (n = 9).

235

236 Chronology of acquired mutations

237 In the underlying clinical case the substitutions emerged in the following chronological order:

S:Y144- emerged immediately after the increase of the specific antibody titre at day 117 as a temporary mutation, followed by E484Q (day 129), which could not assert itself against E484K and was displaced at least 7 days later (day 136). Furthermore, we found the substitutions S:N354K (day 158, 164, 171 und 182), S:R346I (day 164) and ORF1a:T3284I (day 171), S:D950N (day 171) as well as the prominent S:P681H on day 182 (Fig. 2). Three of the six acquired substitutions (50%) have already been described as typical mutations acquired by diverse variants of concern.

Thirteen of the seventeen acquired substitutions (76.5%) occurred in the genomic region coding for spike, and one each in the regions coding for ORF1a:T3284, ORF3a:V255X (day 73), ORF8:Y73C* (day 73) and N:S235F* (day 136) (**Fig. 2**).

Other mutations appeared temporarily and were subsequently replaced by the wildtype variant. Five hitherto undescribed temporary mutations were observed on the days 73 (ORF3a:V255X), 117 (S:A831V), 117 - 123 (S:Y145X), day 129 (S:Y144H), as well as on day 129 (S:E484Q, S:Y144H) (Fig. 3).

252 Six temporary mutations have already been described previously, all of them prominent 253 variations known in the context of variants of concern (https://covariants.org/shared-254 Disease Control and Prevention; mutations; Center for 255 https://www.cdc.gov/coronavirus/2019-ncov/variants/variant-info.html): ORF8:Y73C and 256 S:T716I evolved in the early stage of the infection and are described in the context of the 257 Alpha variant,. S:N501Y, known from the Alpha, Beta, Gamma and Omicron variant, 258 S:del(9) described in the Beta variant, N:S235F, known as a typical substitution of the Alpha 259 variant and S:H655Y, described in the context of the Beta as well as the Omicron variants. 260 All these temporarily recurring mutational events did not establish permanently but 261 disappeared again or were dominated again by the wildtype variant. Figure 3 shows the acquired und temporarily acquired mutations of strain EPI ISL 2106199 in the region coding 262 263 for spike and demonstrates the high concordance of the acquired adaptations with described 264 variants of concern, above all the Alpha and the Omicron variant (15/17; 88.2%). Figure 3 265 represents the adaptations in the region coding for spike. Further mutations in the genome 266 were ORF1a:T3284I (day 171), ORF8:Y73C (day 73), ORF3a:V255X (day 73), N:S235F 267 (day 136), ORF1b:L714- (day 158). Thirteen of the 17 mutations (76.5%) acquired in the 268 course of the prolonged infectious phase are already described mutations in variants of 269 concern. Ten of the 17 spike mutations occur in a similar or identical way in the Omicron 270 variant (58.8%). The non-synonymous mutations S:del143, S:del144, S:N501Y, S:H655Y 271 and S:P681H were developed in identical form in the Omicron variant. Further non-272 synonymous mutations occurred at the amino acid positions S:142, S:144, S:145, S:484 273 (twice) in strain EPI_ISL_2106199 as well as in the Omicron variant, which, however, led to 274 different expressions (S:del142 instead of S:G142D, temporarily both S:Y144H versus 275 S:144del and S:Y145X versus S:145del as well as S:E484Q and S:E484K instead of 276 S:E484A). Overall, 76.5% of all mutations and 88.2% of the spike mutations acquired by 277 strain EPI ISL 21061 convergently evolved in other variants of concern, mainly in the Alpha 278 and the Omicron variant.

279

280

281 Figure 3: The acquired and temporarily acquired mutations of strain EPI ISL 2106199 in the 282 course of a seven months lasting course of infection in an immunocompromised person in 283 the region coding for spike. Overall, 17 persistent or temporary spike mutations were 284 evolved, whereas 9 (52.9%) turned out to be temporary and were subsequently replaced by 285 the wild-type variant. * ... temporary mutations; S1 ... spike 1; S2 ... spike 2; hr ... heptad 286 repeat; RBD ... receptor binding domain; The mutations marked in orange are also found in 287 the Omicron variant (B.1.1.529) in similar or identical expression (10 out of 17), mutations 288 marked in red are found in other variants of concern (3 of 17; 17.6%). Thirteen of the 17 289 mutations (76.5%) acquired in the course of the prolonged infectious phase are already 290 described mutations in variants of concern.

291

Overall, SARS-CoV-2 developed eleven persistent mutations during the study period of 140
 days as well as eleven temporary mutational events. The chronology of intra-host mutational
 events is displayed in Figure 4.

295

296

Figure 4: Chronology of the emergence of intra-host mutations in an immunocompromised patient with adequate humoral and lacking cellular immune response. The study period comprised 140 days of almost permanent viral shedding. High-quality next-generation sequences could be obtained at 14 time-points during the seven-month study period (starting on day 73, ending on day 207 with the last SARS-CoV-2 positive swab) and disclosed the chronological development of mutational events of SARS-CoV-2 as an answer to a unilateral immune response with strong antibody answer but lack of specific T-cells.

304

In the first swab sample, whole genome sequencing did not detect any spike mutations in the investigated strain compared to the reference genome. First spike variants appeared as E484K on day 133 as a heterozygotic mutation in 41.3% of the targeted reads. On day 136 the proportion of E484K increased to 76% and, after more than seven days (day 143) the new variant dominated with 100%, but decreased to 76.8% again on day 158. On day 171 the spike variant P681H was observed for the first time with a proportion of 24% and dominated within a couple of weeks reaching 100% on day 182.

Three of the six acquired substitutions (50%) are previously described substitutions of immune escape variants, namely: S:E484K, S:D950N and S:P681H.

314

315

Figure 5: Chronology of the appearance of convergent intra-host mutations in a strain of the clade B.1.1., as they have been proven in identical form in the variants of concern. α ... mutations are described for the Alpha variant B.1.1.7; β ... Beta variant B.1.351; δ ... Gamma variant B.1.1.28.1; γ ... Delta variant B.1.617.2; α ... Omicron variant B.1.1.529. The red line graph shows the mean frequency of all mutations at a given day. The occurrence of mutations did not occur straight-line, but in a fluctuating course, with frequent replacement by the wildtype variant.

323

324 **The fluctuating occurrence of adaptive mutations**

The emergence of adaptive mutations did not occur in a linear but fluctuating fashion. Frequently, new mutations arose at a certain time point to be later replaced by the wildtype variant, again. As shown in **Figure 5**, the mutation rate shows an oscillating course with

peaks around day 125, increasing until day 182. Simultaneously, the viral load decreased
 continuously until the patient had several consecutive negative SARS-CoV-2 qPCR tests
 since day 232 and is therefore considered to be cured from COVID-19.

331

332 Intra-host evolutionary history

The intra-host evolution of the strain EPI_ISL_2106199 from day 73 and the quasi-species arising from it in the course of the intra-host evolution form a distinct clade in the consensus tree and group together. The clade is embedded in a random composition of complete Austrian strains and variants of concern found in Europe and described and uploaded to GISAID platform in the same study period from January to May 2021 (**Figure 6**). Early Austrian sequences of the Omicron variant from December 2021 were included subsequently.

340

341

Figure 6: Outgroup-routed consensus tree based on 40 SARS-CoV-2 whole genome sequences with 29,806 nucleotide sites. The section highlighted in red shows the monophyletic clade of variants newly formed in an immunocompromised patient, embedded in prominent variants of concern and typical Austrian strains sequenced in the same investigation period, downloaded from GISAID and completed by early Austrian sequences of the Omicron variant in December 2021. Numbers at nodes indicate bootstrap support values (only values > 50 are shown).

349

350

351 DISCUSSION

In this unique case report we described the dynamics of intra-host mutational events in an immunocompromised patient during a seven-months period of prolonged viral shedding and proven infectivity. We considered the possible influence of a quantitatively strong but regarding binding capacities probably functionally ineffective humoral antibody response and a lacking cellular immune response on the site-directed mutagenesis of SARS-CoV-2.

357 Our sequencing approach resulted in high-confidence variant identification and robust 358 genome-wide coverage and enabled the establishment of a chronology of immune escape 359 mutations. In addition, previously undescribed site-directed base-exchanges, found in the 360 regions ORF1a and b (n = 2;ORF1a:T3284I, ORF1b:L714-), ORF3a (ORF3a:V255X) and spike 361 protein (n = 2; S:N354K, S:A831V), were described here. Four different well-established 362 serological methods gave insights into the humoral immune response and demonstrated the 363 inability to clear the SARS-CoV-2 infection despite positive antibody responses. This may be 364 due to the relatively low neutralizing ability of the detected IgG which is also supported by the 365 low avidity of the specific IgG and impaired avidity maturation over time. Administration of 366 IVIG was not able to enhance the clearance of SARS-CoV-2. Cellular immunity was 367 diminished in this patient and the lack of adapted T cell-mediated immune defence may have 368 contributed to the inefficient clearance.

The substitution rate for SARS-CoV-2 was estimated as (8-9) x 10^{-4} nucleotides per site per year (32). This is comparable to previously reported substitution rates of SARS-CoV (8.0-23.8 * 10^{-4}) (33) and MERS-CoV (11.2 * 10^{-4}) (34, 35) and comparable to the reported substitution rates for Influenza A (4-5 * 10^{-3}) and Influenza B (2 x 10^{-3}) virus in the haemagglutinine gene (36). From this substitution rate it can be estimated that SARS-CoV-2 undergoes about one genetic change every other week (32). In comparison, the nucleotide substitution rate per site and per year for Ebola (EBOV Makona) is estimated to be ~1.2 * 10^{-3}

³ (37) and for HIV-1 (3.21-4.06) * 10⁻³ (38). Interestingly, the evolutionary rate stayed constant throughout the first months of infection but decreased slightly after the increase of specific antibodies on day 124. We did not find elevated intra-host substitution rates compared to the general rate reported for SARS-CoV-2 (32). This unaltered intra-host evolutionary rate compared to the global average evolutionary rate suggests that these mutations in an immunocompromised patient, driven by specific antibodies, do not lead to more frequent random genomic changes, but on the contrary to very specific targeted ones.

We assume that the presence of specific antibodies forced directional selection on retaining or regaining infectiousness and thereby strongly favoured directional mutations at particular sites, acting as immune escape mutations.

386 E484K, a substitution in the receptor binding domain (RBD) appeared early in the course of 387 the infection and is described to impair neutralization resistance (39), potentially 388 compromising vaccines effectiveness (4, 6, 40-47). E484K is a well-established distinction of 389 the variants of concern (VOC) B.1.1.7 with E484K, P.1, P.2, B.1.315, B.1.525, B.1.526 as 390 well B.1.617.1 Disease as (Center for Control and Prevention: 391 https://www.cdc.gov/coronavirus/2019-ncov/variants/variant-info.html). At the same position 392 E484, both subtypes of the Omicron variant have formed the alternative substitution alanine 393 A (Center for Disease Control and Prevention; https://www.cdc.gov/coronavirus/2019-394 ncov/variants/variant-info.html). On day 158, the Omicron-specific mutation S:H655Y (48, 49) 395 could also be detected as a temporary substitution. A further genomic change in the region 396 coding for spike was identified on position S:N354K on day 158 and had never been 397 described before. R346I was detected in the sequence of day 164. This mutation was 398 previously described as a reaction of SARS-CoV-2 after monoclonal antibody treatment, 399 seeming to maintain ACE2 binding activity (50) and has also developed in the VOI Mu, 21H, 400 B.1.621 (https://covariants.org/shared-mutations; Center for Disease Control and Prevention; 401 https://www.cdc.gov/coronavirus/2019-ncov/variants/variant-info.html).

S:D950N arose around day 171 and is as adaptive mutation assigned to the Gamma and
Delta variant (Center for Disease Control and Prevention;
https://www.cdc.gov/coronavirus/2019-ncov/variants/variant-info.html).

The substitution P681H was observed for the first time in the sequence of day 171, whereby the amino acid histidine (H) first appeared as a polymorphism to become the dominant and finally fixed variant in the course of the next ten days. This transformation from proline (P) to histidine is relatively well studied and implicates a modification in the neighbouring furin cleavage site at the junction of the spike protein receptor-binding (S1) and fusion (S2) domains (51).

Another major transformation of the spike protein is the deletion of the amino acids 141 to 144. The deletions Y144/145- on the edge of the spike tip are modifications described in the VOC B.1.1.7 as the recurrent deletion region 2 (rdr2), occurring repeatedly in SARS-CoV-2 variants (9, 10).

In our case, the deletions were extended to three more deleted positions on S:141, 142 and
143. S:143del is another analogy to the Omicron variant B.1.1.592.

Nine permanent mutations were found in the spike-coding region. More precisely, four are located in the N-terminal domain (S:L141-, S:G142-, S:V143-, S:Y144-), three in the receptor-binding domain (S:R346I, S:N354K and S:E484K), both parts of S1 and three are positioned in the region encoding for S2, namely P681H in the immediate neighbourhood of the furin cleavage site and S:D905N near heptad repeat 1 as part of the fusion core region.

422 Of the eleven acquired adaptive mutations, only two were found outside the spike-coding 423 regions, namely L714- in ORF1b (day 158) and T3284I in ORF1a (day 171). ORF1a and 424 ORF1b are coding regions for non-structural proteins (nsp) (52). ORF1a:T3284I is located in 425 the region encoding for nsp5. Nsp5 is regarded as the main protease, cleaves viral

polyprotein and works closely with nsp12 and nsp13. Together, nsp5, 12 and 13 represent
the replicase machinery (52-54). ORF1b:L714- is a deletion in the region coding for nsp13,
the enzyme helicase, a main component of membrane-associated replication-transcription
complexes (52, 55-57).

430 It is remarkable that nine of the eleven persistent mutations (81.8%) acquired in the course of 431 the prolonged infection had previously been described in the context of immune escape and 432 were assigned to diverse variants of concern. Our bioinformatic analyses revealed that 75% 433 of the novel mutations in our investigated strain also occur in variants of concern, whereas 434 the highest concordance was found between strain EPI ISL 2106199 and the Omicron 435 variant (50%). Furthermore, we found dynamic mutational events with fluctuations between 436 the wildtype and the variational mutation. Nine of these temporary mutations (9 of 11; 81.8%) 437 have also been described in the context of variants of concern (Center for Disease Control and Prevention; https://www.cdc.gov/coronavirus/2019-ncov/variants/variant-info.html). In the 438 439 close proximity of the acquired deletion in ORF1b:L714-, which manifested homozygously, 440 additional conspicuous polymorphic sequences in amino acid position ORF1b:708-716 were 441 found. We measured frequent changes in substitutions and deletions. This certainly left us 442 with the impression of mutational escape manoeuvres. Also, this hotspot in directional 443 mutations encodes for nsp13, the helicase.

We thus suggest that the accumulated mutations are results of an increased selection pressure on spike, the key to entering the host cell. At the same time a second process takes place intra-host, which exerts increased pressure and enforces continual reconstructions in nsp13. The findings of these temporary mutations, which almost exclusively occurred in the spike region, also fit this pattern very well.

We managed to isolate SARS-CoV-2 from swabs at different time points, which is further evidence for the continuous viability of the virus over the study period, given the evolutionary dynamics of the different sequences. The isolation success correlated negatively with the Ct value, a fact that has already been observed in previous studies (22).

Treatment with Rituximab resulting in depletion of particularly memory and effector B cells by 453 454 targeting CD20 is known to cause impaired antibody responses (58-60). As naïve B cell 455 clones are less sensitive to Rituximab treatment due to their lower expression of CD20, a 456 robust immune response can also be assumed for those patients. Immunosuppressive 457 therapy as well as the lymphoma disease itself may have diminished the T cellular axis of 458 immune defence against SARS-CoV-2, which targets infected cells, and loss of control by 459 cytotoxic T cells may have caused the ongoing replication of SARS-CoV-2 in naso-460 pharyngeal epithelial cells (61, 62). Impaired T cell help may have contributed to the 461 inefficient antibody maturation.

Meanwhile, there are more studies that shed light on the evolution of immune escape variants in immunocompromised patients and support the results of our study (12, 63-69).(12, 63-69) Nonetheless, our study not only shows the accumulation of an unusually high number of immune escape mutations in a single patient, which to a strikingly high degree evolved in parallel in various variants of concern. The chronology of mutation events during seven months of infection shows a rapid accumulation of non-synonymous mutations which in part were persistent, in part temporary or even repeatedly acquired and lost.

469 In summary, our case report documents the medical phenomenon of persisting SARS-CoV-2 infection in an immunocompromised patient with impaired humoral and cellular immune 470 471 response. Potential interference of specific antibodies led to a significant reduction in the viral load, but at the same time generated sophisticated escape mechanisms while the cell-472 473 mediated immune defence for eradication of the infection is missing. With the aid of NGS, we 474 witnessed the directed mutational changes of SARS-CoV-2, probably facilitated by 475 insufficient humoral immune defence. This led to the formation of highly specific virus 476 variants, highlighting the regions exposed to the highest intra-host selective pressure. Based

477 on this observation one may hypothesize that immunocompromised patients pose a 478 particular risk to establish a source of immune escape mutants of SARS-CoV-2. Our study 479 also underlines the importance to protect these patients from SARS-CoV-2 infection by 480 modified vaccination strategies as well as to reinforce vaccination efforts to increase herd 481 immunity in general. Most importantly, the study points out the convergent evolution of 482 specific mutations in SARS-CoV-2, both in VOCs, VOIs and intra-host in the strain we studied (EPI ISL 2106199). Those specific, convergently evolving mutations reveal those 483 484 neuralgic positions in the SARS-CoV-2 genome that on the one hand represent its highest 485 fitness advantage, but on the other hand also uncovers its highest vulnerability and should 486 be considered as the probably most important points of attack in future vaccine and 487 therapeutics development.

488

489 **METHODS**

490 Immunological diagnostics

491 CLIA SARS-CoV-2 TrimericS IgG

Serological tests were performed using the LIAISON® SARS-CoV-2 TrimericS IgG (DiaSorin
S.p.A., Saluggia, Italy) (LIAISON), an Immunoblot called ViraChip® assay (Viramed, Munich,
Germany) and an in-house enzyme-linked neutralization assay (ELNA) (14) at day 102, 124,
182 and 205 after the first positive PCR.

The LIAISON® SARS-CoV-2 TrimericS IgG is a CLIA (Chemiluminescent Immunoassay) which detects IgG antibodies reactive with the spike protein (S1/S2 domain). The assay was performed on the LIAISON® XL Analyzer according to the manufacturer's instructions and gives the arbitrary units per ml (AU/mL) according to the WHO International Standards for the Anti-SARS-CoV-2-immunoglobulin-binding activity (NIBSC 20-136).

501 Microarray immunoblots

The ViraChip® assay detects temporal antibody profiles of different immunoglobulin classes against S1, S2, and nucleocapsid (N) as well as against N of the four nonSARS human coronaviruses in a commercial, miniaturized 96 wells protein microarray. The ViraChip® assay is a useful tool to identify the epitope-specificity of IgG and IgA in serum samples. The quantitative antibody measurement was performed on a ViraChip® Scanner using ViraChip® Software.

508 Neutralization test

509 Neutralization ability of antibodies was determined performing an in-house enzyme-linked 510 neutralization assay (ELNA) as described elsewhere (14).

511 Anti-IgG-SARS ELISA

512 Serum IgG antibodies against SARS-CoV-2 were determined by Serion agile SARS-CoV-2 513 ELISA with a sensitivity of 96.2% and a specificity of 100% according to manufacturer's 514 instructions (Virion/Serion, Wuerzburg, Germany). Antibody activities above 15U/mL were 515 considered positive.

516 Anti-IgG-SARS-Avidity

Relative avidity index (RAI) was determined by a modification of the Serion agile SARS-CoV-2 IgG-SARS ELISA using 1M ammonium thiocyanate (NH₄SCN) as a chaotropic agent as described previously (15-17). RAI values were considered as: RAI > 60% high avidity, 40% < RAI < 60% as moderate, and RAI < 40% as low avidity in reference to other viral infections (18).

522 SARS-CoV-2 specific T cell response

523 The ELISpot assay was performed using a commercially available precoated human SARS-524 CoV-2-specific IFN-y ELISPOT kit according to the manufacturer's protocol (AutoImmun 525 Diagnostika, GmbH, Germany; Cat.no. ELSP 5500). Peripheral blood was collected into 526 tubes coated with lithium-heparin (Vacuette, Greiner bio-one, Austria). PBMCs were 527 separated from plasma and whole blood by gradient density (FicoLite® -H, Linaris, Germany). After washing with phosphate-buffered saline (PBS), depleting erythrocytes 528 529 (RBD-Lyse Buffer Life Technologies, 1xRBC Lysis Buffer 200ml; Invitrogen eBioscience, 530 USA REF: 00-4333-57) and washing again with PBS, cells were counted and resuspended in 531 x-vivo medium (X-VIVO TM-10 Serum-free hematopoietic cell medium; BEBP02-055Q, 532 Lonza, Switzerland).

Briefly, a total of 2 x 10⁵ PBMCs were incubated in duplicate with x-vivo as a negative 533 534 control, pokeweed mitogen (AutoImmun Diagnostika GmbH, Germany) as a positive 535 control,15-20mer peptide pools for SARS-CoV-2 (AutoImmun Diagnostika GmbH, Germany) 536 and PanCorona (AutoImmun Diagnostika GmbH, Germany) for the four nonSARS human 537 coronaviruses 229E, HKU1, NL63 and OC43 as a control of possible cellular cross-reactive 538 responses. After incubation at 37° C for 20 hours in a sterile and humidified atmosphere, 539 plates were washed with washing buffer (AutoImmun Diagnostika GmbH, Germany) and 540 stained with the kit-specific reagents according to the manufacturer's protocol. Plates were 541 then washed several times under running water and dried overnight. Spot forming units 542 (SFU)/100.000 cells were counted using an automated AID ELISPOT reader system 543 (AutoImmun Diagnostika GmbH, Germany).

544 The assessment criteria for the ELISpots were a minimum of 50 SFU in the positive control 545 and a maximum of 10 SFU in the negative control according to the manufacturer's definitions 546 (19, 20). When those criteria were fulfilled, the stimulation index (SI) was calculated by 547 dividing the mean SFU numbers in the antigen-specific wells with the mean SFU numbers of 548 the negative control. The test was assessed negative with an SI < 2 according to previous 549 determination of the cut-off by well-defined pre-pandemic PBMC samples and by PBMCs 550 from SARS-CoV-2-naive individuals. The test was suggested to be poorly reactive with an SI 551 between 2 and 7 and reactive with an SI \geq 7 as defined by the manufacturer (19). According 552 to standardized laboratory procedures, in each assay, a standard laboratory control sample 553 of a high-reactive and a non-reactive PBMC sample, respectively, was run to determine inter-554 assay-variations. Only assays with less than two standard deviations of the high-reactive and 555 the non-reactive PBMC control sample, respectively, were defined valid.

556 Sample collection

557 Nasopharyngeal swabs were taken in a standardized way in home quarantine in the context 558 of primary care by a medical co-worker.

559 **RNA extraction**

Nucleic acids were isolated using the MagMAX[™]-96 Total RNA Isolation Kit (Thermo Fisher 560 561 Scientific, Waltham, Massachusetts, USA; Cat. No. AM1830). Briefly, 200µl PBS were taken from patient swab sample and mixed with 265µL binding buffer, 5µl proteinase K (20mg/mL) 562 563 and 5µL extraction control (Thermo Fisher Scientific, Waltham, Massachusetts, USA; Cat. No. AM1830) according to the KingFisher[™] extraction protocol for 200µL sample volume 564 565 (Thermo Fisher Scientific, Waltham, Massachusetts, USA). After incubation at room 566 temperature for at least 15 minutes, samples were transferred from tubes into 96-well 567 KingFisher deep well plates (Thermo Fisher Scientific, Waltham, Massachusetts, USA) 568 containing 280µl isopropanol and 2µL Mag-Bind particles per well, using a KingFisher[™] Flex purification system (Cat. No. 5400620). 569

570 <u>rtPCR</u>

qPCR extracts were tested for SARS-CoV-2 by qRT-PCR using the Bio-Rad CFX96 system
 (Bio-Rad, Germany) with a LightMix Modular Assay kit in accordance with the modified

573 Charité guidelines (Corman et al., 2020). 10µL of extracted RNA were added into 15µL 4x Reliance One-Step Multiplex Supermix (Bio-Rad, Germany). Each 15µL mastermix 574 contained 12.5µL buffer solution, 0.25µl enzyme mix, 1.75µL of nuclease-free water and 575 576 0.5µL primer probe wHCoV (E-Gene, as well as N-Gene and Rdrp-Gene for confirmation). Reactions were incubated at 55° C for 5 min and 95 C for 5 min in order to conduct reverse 577 578 transcription of viral RNA, sample denaturation and enzyme activation. These steps were 579 followed by PCR-amplification including 45 cycles at 95° C for 5 s, 60° C for 15 s and 72° C for 15 s. Cooling was implemented at 40° C for 30 s. Results were interpreted based on the 580 581 Second Derivative Maximum (SDM) method. Positive results were confirmed by Rdrp and N-582 gene (21), samples with an initial Ct value lower than or equal to 37 were assigned to 583 repeated testing including extraction. A Ct value higher than 40 was considered negative. 584 Quantification of the viral load in the swabs was calculated via size standards of 1, 10, 100 585 and 1000 plaque-forming units (PFU)/mL. Standardization of viral stocks was carried out by virus titration. Isolation was performed on VeroB4 cells as described elsewhere (22). 586

587 <u>Virus titration</u>

588 Confluent VeroB4 cells were cultured in Medium199 including 5% FCS in T75 tissue culture 589 flasks (Sarstedt, Germany) and transferred into 96-well tissue culture plates (Sarstedt, 590 Germany). Passage 1 isolates of SARS-CoV-2 were thawed from -80° C freezer and titrated 591 from 1:10 to 1:10⁻¹² in U-shaped 96-well plates (Greiner, Germany) and pipetted into each corresponding well of the 96-well tissue culture plate. Plates were incubated at 36° C. Three 592 593 days post infection, incubation was stopped by gently removing the supernatant, washing the 594 cells three times with PBS and fixing cells in 1:1 ice-cold acetone-methanol. For easier 595 optical evaluation, cells were dyed by crystal violet staining and tissue culture infectious dose 596 of 70% (TCID₇₀) and PFU were calculated (Ramakrishnan, 2016).

597 Whole genome sequencing and mutational analysis

598 Libraries were prepared according to the Ion AmpliSeg[™] SARS-CoV-2 Research Panel 599 (Thermofisher, USA), library construction and sequencing protocol with the Library Kit Plus 600 (Thermo Fisher Scientific, Waltham, Massachusetts, USA; Cat. No. 4488990). The Amplicons were cleaned up with AMPure XP beads (Beckman Coulter, Germany) with a 1:1 601 ratio. The libraries were quantified using the Ion Library TaqMan[™] Quantitation Kit (Cat. No. 602 4468802), normalizing, pooling and sequencing was performed using an Ion Torrent[™] S5 603 604 Plus. Ion Torrent Suite software (v 5.12.2) of the Ion S5 sequencer was used to map the 605 generated reads to a SARS-CoV-2 reference genome (Wuhan-Hu-1; GenBank accession 606 numbers NC_045512 and MN908947.3), using TMAP software included in the Torrent Suite. 607 The following plugins were used: Coverage Analysis (v5.10.0.3), Variant Caller (v.5.12.04) 608 for mutation calls both with "Generic □ S5/S5XL (510/520/530) □ Somatic □ Low Stringency" 609 and "Generic S5/S5XL (510/520/530) Germ Line Low Stringency" default parameters and 610 COVID19AnnotateSnpEff (v.1.0.), a plugin specifically developed for SARS CoV 2 that can 611 predict the effect of a base substitution. No ultra-deep sequencing was performed and only 612 mutations visible in the stated analysis methods were listed and rated.

613 FASTA files containing the raw reads were inspected for quality criteria (mapped, targeted, 614 filtered reads, mean depth and uniformity) using Thermofisher Software. Multiple sequence 615 alignments were performed using Unipro UGENE (23) as well as MEGA X (Kumar et al., 616 2018). The SARS-CoV-2 genomes were compared to the reference NC 045512.2-Wuhan-617 Hu-1. Viral genome assembly and screening for distinct mutations was performed online 618 (https://github.com/nextstrain/ncov/blob/master/defaults/clades.tsv; using nextstrain.org 619 https://clades.nextstrain.org/). The identification of pangolin lineages was carried out using 620 Pangolin software, v.2.4.2. (https://pangolin.cog-uk.io/). The generated full-genome 621 sequences are available at GISAID EpiCoV (https://gisaid.org/no.EPI_ISL_2106191-622 21061201). Additional sequences of frequent Austrian strains and prominent variants of

623 concern, sequenced in the same study period, were retrieved from the GISAID EpiCoV 624 database (24) to calculate a consensus tree.

Indels were coded using 'simple indel coding' (25) as implemented in 2matrix v.1.0 (70).

The best-fit model of nucleotide substitutions (TIM2+F+I) was selected under the Akaike and the Bayesian formation criteria using ModelFinder (71) as implemented in the PhyloSuite Software package (26). Phylogenomic inference was based on a Maximum Likelihood (ML). An ML tree with 5000 ultrafast bootstrap replicates was inferred in the IQ Tree plugin (27, 28) of PhyloSuite.

631 Bioinformatics CoV-Seq Workflow

The frequency of the various mutations and the homology to the most widespread variants of 632 633 concern (Alpha-, Beta, Gamma- and Delta-variant) were investigated based on BAM files. 634 Reads from CoV-Seq samples were demultiplexed by using in-house tools. Reads 635 originating from human were filtered out by mapping against hg38 with bwa-mem 0.7.17 (29). 636 All reads not mapping to human were trimmed for adapters und quality by using Cutadapt 637 3.2(30). The trimmed reads were mapped with bwa-mem 0.7.17 to the SARS-CoV-2 638 reference MN908947.3 from the NCBI. Mutations were called using breseq 0.35.5 (31). 639 Graphics were created using *pandas* 1.2 for Python 3.

640 Statistics

bichotomous data were evaluated by a chi-squared test or Fisher's exacta in the case of small group size (n < 60) (Microsoft® Excel®, Microsoft 395 MSO, Windows 10). A two-sided significance level of p < 0.05 was used for determining statistical significance. After testing for distribution (Kolmogorov-Smirnov-test), non-parametric continuous independent variables were compared using Mann-Whitney-U test for each time point. Dependent non-parametric variables were compared using Wilcoxon-rank test.

Kopecky**: Visualization, Organization. **Giovanni Almanzar**: Methodology. **Stephan Koblmüller**: Conceptualization, Writing – editing, Funding acquisition. **Christian Sturmbauer**: Conceptualization, Writing – editing, Funding acquisition. **Leonard Feist:** Validation, Verification. **Ralf Horres:** Validation, Verification. **Wilfried Posch**: Validation, Supervision. **Gernot Walder**: Supervision.

ETHICAL APPROVAL

All clinical samples and data were collected for routine patient care and for public health interventions. The patient gave full written consent for the case to be attended and published. Ethical approval to use residual routinely taken serum samples for retrospective analyses was obtained by the Ethics Committee of the University Hospital Wuerzburg (no. 20201105_01).

COMPETING INTERESTS

The authors have no conflict of interest to declare.

DATA AVAILIBILITY

The generated full-genome sequences are available at GISAID EpiCoV (https://gisaid.org/no.EPI_ISL_2106191-21061201).
