## ABSTRACT

The prevalence of Alzheimer's disease is projected to reach 13 million in the U.S. by 2050. Although major efforts have been made to avoid this outcome, so far there are no treatments that can stop or reverse the progressive cognitive decline that defines Alzheimer's disease. The utilization of preventative treatment before significant cognitive decline has occurred may ultimately be the solution, necessitating a reliable biomarker of preclinical/prodromal disease stages to determine which older adults are most at risk. Quantitative cerebral blood flow is a promising potential early biomarker for Alzheimer's disease, but the spatiotemporal patterns of altered cerebral blood flow in Alzheimer's disease are not fully understood. The current systematic review compiles the findings of 29 original studies that compared quantitative cerebral blood flow in older adults with mild cognitive impairment or Alzheimer's disease to that of cognitively normal older adults and/or assessed the relationship between cerebral blood flow and objective cognitive function. Individuals with Alzheimer's disease had relatively decreased cerebral blood flow in all brain regions investigated, especially the temporoparietal and posterior cingulate, while individuals with mild cognitive impairment had less consistent results, with relatively increased cerebral blood flow reported in the temporal lobe and thalamus. Most papers reported a positive correlation between cerebral blood flow and cognitive function. This review highlights the need for more studies comparing cerebral blood flow between cognitively normal individuals and those with mild cognitive impairment, as well as the importance of including potential confounding factors in these analyses.

Key words: cerebral blood flow, neuroimaging, biomarker, Alzheimer's disease, mild cognitive impairment

Abbreviations: AD: Alzheimer's disease, ASL: arterial spin labeled, *APOE*: apolipoprotein E, CAMCOG: Cambridge Cognition Examination, CBF: cerebral blood flow, CN: cognitively normal, DCE: dynamic contrast enhanced, MCI: mild cognitive impairment, MRI: magnetic resonance imaging, PET: positron emission tomography, SCD: subjective cognitive decline, SD: standard deviation, SPECT: single-photon emission computerized tomography

## INTRODUCTION

Alzheimer's disease (AD) is the leading cause of dementia; 60-80% of dementia cases are attributable to AD (Alzheimer's Disease Facts and Figures, 2021). Both the prevalence and mortality rate of AD are increasing in the U.S. and globally, and there are no current treatments that can stop or reverse the progressive loss of cognitive function caused by AD (Alzheimer's Disease Facts and Figures, 2021). Clinical trials of treatments targeting pathologic forms of amyloid- $\beta$  and tau proteins in the brain have successfully reduced them but have been unable to stop the progression of cognitive decline (Zhu et al., 2020). In order to effectively treat AD, a preventative treatment administered before irreversible neuronal damage has occurred may be necessary (Zhu et al., 2020). An effective early biomarker for the identification of older adults who are most likely to develop AD is critical (Blennow & Zetterberg, 2018; Counts et al., 2017). The disease process of AD can begin decades before cognitive decline is apparent and can manifest as subjective cognitive decline (SCD) or mild cognitive impairment (MCI; Petersen et al., 1999; Petersen, 2016; Jessen et al., 2014; Jessen et al., 2020). MCI is a stage of decreased cognitive functioning measured on objective cognitive tests accompanied by the preserved ability to complete day-to-day activities (Petersen et al., 1999). SCD, during which individuals still perform in the normal range on objective cognitive tests but report a subjective decline from their normal cognitive state, has been described as an even earlier stage of AD (Jessen et al., 2014). An effective early biomarker for AD that can lead to preventative treatment must be able to distinguish individuals with SCD and MCI from normally aging individuals and from older adults experiencing cognitive changes due to other reasons, such as depression (Culpepper et. al., 2017).

Cerebral blood flow (CBF) is a potential early biomarker for AD. CBF is globally decreased in patients with AD compared to age-matched non-demented counterparts. It has been shown that CBF is altered in individuals with preclinical AD as well, and that patterns of altered CBF are correlated with disease severity and progression from one diagnostic stage to the next (Duan et al., 2021). Due to the brain's sensitivity to changes in blood pressure, chronic hypertension leads to constriction of the cerebral vasculature. Additionally, blood vessels in the brain become more rigid with age, so the combination of chronic hypertension and aging lead to a hyper-constricted cerebral vasculature and ultimately chronically reduced CBF (Iadecola & Gottesman, 2019). Although the longstanding amyloid cascade hypothesis of AD posits that amyloid- $\beta$  and its aggregation ultimately lead to the disease processes and outcomes in AD (Hardy & Higgins, 1992), the more recently suggested two-hit hypothesis states that cerebrovascular dysfunction and amyloid- $\beta$  pathology culminate to initiate and propagate AD (Zlokovic, 2011).

CBF has been studied in the context of AD and other dementias for several decades and has been measured by a variety of neuroimaging methods over time. The first measurements of CBF in humans were made in 1948 using the inhalation of nitrous oxide and quantification of the inert gas in venous blood (Kety & Schmidt, 1948). In the 1960s, the use of radioactive tracers including krypton-85 and xenon-133 allowed for the measurement of regional as well as global CBF (Lassen & Ingvar, 1961; Lassen et al., 1963). The development of positron emission tomography (PET) soon led to the use of positron-emitting tracers, particularly oxygen-15, for CBF measurement (Jones et al., 1976). Dynamic contrast enhanced magnetic resonance imaging (DCE MRI) and dynamic susceptibility-contrast (DSC) MRI were developed around the same time as PET and utilized gadolinium-based contrast agents that had magnetic properties to trace

and quantify CBF without the need for radioactive tracers. (Edelman et al., 1990; Rempp et al., 1994; Maeda et al., 1993).

The most common methods of the studies included in this review are single-photon emission computerized tomography (SPECT) and the more recently developed arterial spin labeled (ASL) MRI. SPECT requires the blood to be labeled with an injection of a radioactive tracer, such as iodine-123 or technetium-99m (Warwick, 2004). ASL MRI, on the other hand, is completely noninvasive. In ASL MRI, blood is labeled as it flows into the brain by inverting the magnetization of the water molecules in the blood and then comparing the labeled image to an unlabeled background image (Detre et al., 2012). ASL MRI can therefore be safely and comfortably used at multiple time points to monitor changes in CBF over the course of disease or treatment.

In order to utilize CBF as an early biomarker for AD, we need to better understand how CBF changes throughout the progression of AD, including in prodromal stages. The roles of other AD-related pathologies (amyloid- $\beta$ , tau, gray matter atrophy, white matter hyperintensities), AD risk factors (apolipoprotein E (*APOE*)  $\epsilon$ 4 genotype, diabetes, hypertension, and other cardiovascular diseases), and demographic factors (age, sex, race/ethnicity, education, environmental risk factors) must also be taken into consideration when measuring CBF.

The purpose of this review is to consolidate the literature comparing CBF in older adults with MCI or AD to those that are cognitively normal (CN). Patterns of altered CBF will be summarized using results from several brain regions. Results will also be summarized for the relationship between cognitive exam scores and CBF in older adults. The aim is to compile and synthesize the results of the existing literature concerning altered CBF in AD. This is important because various methods of CBF measurement have been used over the years; standardization of

results will help to clarify whether previous findings are consistent. A recently published review (Zhang et al., 2021) covers the same topic with a broader scope. It includes studies that measured CBF velocity, and it does not exclude articles based on the age of participants with AD. However, Zhang et al. (2021) do not include papers that report voxel-wise results in the form of  $z$  or  $t$  scores. The current review employs an age cutoff for the AD participants included because early onset AD, diagnosed before age 65, may be a different variant of AD; early onset AD patients tend to decline more rapidly and are more likely to have cognitive declines in areas other than memory as the initial symptoms. Therefore, we excluded papers where the mean age of AD participants minus two standard deviations (SDs) is less than 60, meaning that nearly 98% of the individuals studied in each paper are at least 60 years old. This defines the overall AD population as mostly late onset. We also included papers that report voxel-wise results to assess their consistency with papers that report regional CBF values.

The objective of this review is to assess the cumulative evidence of altered CBF in older adults with MCI and AD in multiple brain regions and of the relationship between CBF and cognitive exam scores in these individuals. We also aim to assess the consistency of findings across papers that use a variety of imaging, processing, and analytic methods. Our main question is one of correlation rather than causation between diagnosis and CBF. In reality, it is likely that AD pathologies and altered CBF exacerbate one another and have a cyclical relationship, and it is not clear which of the two is present first or whether both arise simultaneously from a common cause.

## METHODS

This systematic review includes all studies in which resting CBF is compared between diagnostic groups (CN, MCI, AD) and/or correlated with cognitive exam scores. Only studies in which the mean age of AD patients minus two SDs is at least 60 years old are included. If there was not a SD listed for age of participants with AD, that paper was not eligible unless the minimum age was at least 60. We chose to use a cutoff for participant age so that a majority of the AD patients would be over the age of 60 and less likely to have early-onset variants of AD. Both observational studies and clinical trials that measured CBF at rest prior to treatment are included, as well as both cross-sectional and longitudinal designs. Only manuscripts written in English were included. All manuscripts are published as original research papers or brief reports; conference abstracts were not included. There were no restrictions on the year of publication, and papers that used any established method for the quantification of CBF were eligible for inclusion. Studies that were ineligible either did not measure CBF at rest or did not use resting CBF as an outcome measure in multiple diagnostic groups and/or in comparison with cognitive test scores.

PubMed was searched on March 23, 2021, through the National Library of Medicine and with access via Indiana University School of Medicine. 1197 potential articles resulted from a PubMed search of “brain-blood supply” and “Alzheimer’s disease” in all fields. We did not specify article type or language in the initial PubMed search in order to be inclusive of all possibly relevant articles. The search terms were chosen from PubMed MeSH terms that broadly encompassed the intended key topics of CBF and Alzheimer’s disease.

Due to the correlational nature of the research question, the “population, intervention, control, and outcomes” (PICO) method (Richardson et al., 1995) was not used. Unlike an

intervention and outcome, CBF and MCI/AD do not have a clear causal relationship. Therefore, the design used for bias and certainty assessments was a case-control research question in which the condition was MCI/AD and the variable of interest was altered CBF.

For the main synthesis, we describe increase or decrease in CBF between AD and controls in several brain regions. Altered CBF in MCI relative to controls and correlations between CBF and cognitive test scores are described as well. For papers that present relevant data only in the form of a graph, we extracted quantitative data using WebPlotDigitizer version 4.5 ([automeris.io/WebPlotDigitizer/](http://automeris.io/WebPlotDigitizer/)). For articles that had a high potential of overlapping participant samples, the article with the higher quality rating (less risk for bias) was chosen.

The information recorded for each article were: author(s), article title, year of publication, place of the study, number of participants, diagnostic groups, criteria by which diagnoses were defined, method used to measure and quantify CBF, ages of participants, whether the paper is included in the synthesis, and which outcomes were reported. To organize this information, we used a matrix from University of Maryland Research Guides ([lib.guides.umd.edu/SR/steps](http://lib.guides.umd.edu/SR/steps)).

To assess the risk of bias and the quality of each article, we used the NIH Quality Assessment of Case-Control Studies. The items on this tool were: clearly stated objective, clearly specified and defined population, sample size justification, use of same population for cases and controls, use of same inclusion and exclusion criteria for cases and controls, clearly defined and differentiated cases, random selection of sample from eligible individuals, use of concurrent controls, confirmation that exposure occurred prior to the condition, clearly defined and reliable measures of exposure/risk, blinded assessment of exposure/risk with regard to case/control, and use of matching or addition of confounding variables to statistical models. Overall judgments were “poor,” “fair,” or “good.” These decisions were made according to the guidance included in

the tool, where it is explained that lack of some criteria correspond to “fatal flaws” while others do not greatly affect the overall quality of the paper. CBF was considered the “exposure,” and because the direction of causation between AD and altered CBF is outside the scope of this review, it was not relevant whether the exposure occurred prior to the condition. Therefore, this question was marked as “not applicable” and not used in the overall bias rating. Other items on the rating tool that were not used were: sample size justification, random selection of sample from eligible individuals, and use of concurrent controls, because these items were all either not present or not reported in all or nearly all papers assessed. In addition, blind assessment of the CBF was not applicable for many of the papers because the CBF was measured by fully automated methods. This item was considered for those papers in which hand-drawn regions of interest were used.

For each relevant paper, we reported mean and SD of CBF in each brain region for each diagnostic group. For articles that used voxel-wise measurement of CBF and reported the z or t scores of peak voxels, these scores, along with cluster sizes and p values are reported. For papers that measured the correlation between CBF and cognitive test scores, r and p values are reported. For papers with mean and SD regional CBF values, effect sizes were calculated, and syntheses were presented for multiple brain regions. To measure effect size, we used Hedge’s g, which is Cohen’s d adjusted for small sample sizes, as well as the 95% confidence interval for Hedge’s g. These effect size measures were chosen because CBF is a continuous measure that is dependent on the methods of scanning and processing, so standardized measures were necessary. Effect size was calculated for the difference in CBF between MCI/AD and control groups (control CBF minus MCI/AD CBF) in the following brain regions: frontal, temporal, parietal, temporoparietal, occipital, posterior cingulate, hippocampus, and thalamus. These regions were chosen because

they were the most frequently used across all papers. Thresholds were not employed for the effect sizes; we synthesized results for each brain region across studies by reporting the average, median, and range of effect size scores in each region. All Hedge's  $g$  values and 95% confidence intervals are presented in graphs; positive effect sizes denote relatively decreased CBF in MCI/AD compared to controls. These analyses and graphs were completed using the Effect Size Calculator from the Cambridge Centre for Evaluation and Monitoring (<https://www.cem.org/>).

A meta-analysis was not performed. Heterogeneity is discussed where there is inconsistency in findings across papers, but statistical analyses regarding heterogeneity were not completed. Sensitivity analyses were also not completed. The scope of this paper is to compile and present the findings in the literature and to discuss overall patterns of results. Reporting bias is taken into account, and certainty ratings for each synthesis are presented in the summary of findings table. Grey literature was not included. Negative findings were included whenever they were reported. For the certainty assessment, we used the GRADE tool from the Cochrane handbook. Scores are “very low,” “low,” “moderate,” and “high.” Since this tool is designed for randomized clinical trials, it instructs the assessor to begin with “moderate” for observational or case-control studies. We rated each synthesis according to the rest of the GRADE criteria but did not strictly begin at “moderate” for each paper because, by design, most of the papers were not clinical trials.

## RESULTS

Of 1197 potential articles resulting from a PubMed search of “brain-blood supply” and “Alzheimer's disease”, 185 were retained for further assessment and 1012 were excluded based on their abstracts. Of those excluded, 352 were reviews, editorials, commentaries, case studies,

and other types of articles that did not match the eligibility criteria. 325 did not use resting CBF as an outcome measure, and 157 used animal models or cell cultures rather than human participants. Finally, 94 did not include participants with various diagnoses or levels of cognitive functioning, and access was not available for 84 articles. Of the 185 retained, 29 articles were ultimately chosen for inclusion in this review, and 156 were excluded. Of these, 97 sampled AD patients who were too young or whose ages were not clearly defined, 25 did not use resting CBF as an outcome, 17 did not compare CBF between diagnostic groups or correlate it with cognitive function, 5 included participants with potentially confounding conditions, 3 were out of scope, 2 included patients with AD who were on psychotropic medication, and 7 were likely to have used the same sample as other articles included in this review. The process of choosing relevant articles is presented in Figure 1.

The papers considered “out of scope” include Iturria-Medina et al. (2017), in which the authors create a 4D multifactorial causal model of AD; Moretti (2016), which focuses on and groups participants by alpha power ratio on EEG; and Vogel et al. (2005), which measures and compares the heterogeneity of CBF rather than a measure of CBF itself. Papers that include patients and/or controls with other illnesses are: Jagust et al. (1990; half of the AD patients have early onset AD), Dougall et al. (2004; some controls have major depression), Starkstein et al. (1994; some controls have dizziness), Cho et al. (2010; controls have headaches or syncope), and De Reuck et al. (1992; the dementia group includes Pick’s disease and Creutzfeldt-Jakob, and the nondemented group includes stroke and encephalopathy). The papers with potentially overlapping samples were: Hanyu et al. (2003; with Hanyu et al. [2004]), Haji et al. (2015; with Kimura et al. [2011]), Brown et al. (1997; with Brown et al. [1996]), Colloby et al. (2002; with

Firbank et al. [2011]), Kawamura et al. (1991) and Mortel et al. (1994; with Obara et al. [1994]) and Pearlson et al. (1992; with Harris et al. [1991]).

Papers included in this review are listed and characterized in Supplementary Table 1. They include: Alegret et al. (2010), Benoit et al. (2002), Brown et al. (1996), Claus et al. (1994), Dai et al. (2009), Ding et al. (2014), Encinas et al. (2003), Firbank et al. (2011), Hanyu et al. (2004), Hanyu et al. (2008), Harris et al. (1991), Iizuka and Kameyama (2017), Jagust et al. (1987), Johnson et al. (2007), Kimura et al. (2011), Lacalle-Aurioles et al. (2013), Lee et al. (2003), Mubrin et al. (1989), Nagahama et al. (2003), Obara et al. (1994), Sase et al. (2017), Schuff et al. (2009), Shimizu et al. (2005), Sundstrom et al. (2006), Takahashi et al. (2008), Tateno et al. (2008), van de Haar et al. (2016), Yew and Nation (2017), and Yoshida et al. (2011). Supplementary Table 1 provides the following information for each included article: author, title, year of publication, location of the study (or study authors), sample size by diagnostic group, criteria used to define diagnostic groups, type of scan used to measure CBF, ages of participants in each diagnostic group, whether the paper was included in the synthesis, and which outcomes of interest were included. Notes are included to clarify special circumstances as necessary. Of the 29 papers, 19 measure CBF using SPECT, 6 using ASL MRI, and 4 using other methods. Publication dates range from 1987 to 2017.

Table 1 reports the component scores and overall quality rating on the risk of bias assessment for each paper. Justification for each score is given in the “Overall Quality Rating and Notes” column. Of the 29 papers, 9 were rated as “good,” 13 were rated as “fair,” and 7 were rated as “poor.” All but one of the papers rated “poor” lacked cognitive test scores for the CN group, without which it is not clear that the CN group is free of cognitive decline. Sundstrom et

al. (2006) was rated as “poor” because the CN group was younger than the AD group, and age was not used as a covariate in the analyses.

Table 2 and Supplementary Tables 2 and 3 report the results of interest for each study. Table 2 reports the comparison of CBF in CN and AD groups (notes clarify which papers include MCI in one of these groups), Supplementary Table 2 reports the comparison of CBF between CN and MCI groups, and Supplementary Table 3 presents correlations between CBF and cognitive exam scores. In Table 2 and Supplementary Table 2, regional CBF data is given as mean (SD) for each group. For regional CBF in these tables and further analyses, values for left and right regions were averaged, with SDs pooled; this was also done across smaller brain regions within those of interest. When bilateral averaging was done, or when only one hemisphere was included in a given paper, this is clarified in the “Notes” column. For voxel-wise results, cluster size (k), p value, and z or t value are reported, and the specific region where the peak voxel is located is given in the “Notes” column. For all effect sizes, a positive value represents a *decrease* in CBF in patients relative to CN, as this was how the results were reported in nearly all of the papers. The “Notes” column also mentions if the data were extracted from a graph rather than reported numerically in the paper. Papers with qualitative results are included in this table as well, for completeness. All papers used quantitative or semi-quantitative methods to measure CBF; papers that assessed CBF simply by visual inspection were not included in this review. Supplementary Table 3 reports r and p values for the correlation of regional CBF and cognitive test scores with details in the “Notes” column.

Overall, most of the papers reported decreased CBF in AD relative to controls in all brain regions we included. Increased CBF in AD relative to controls was reported in some papers in the following regions: frontal and temporal lobes, hippocampus, and thalamus. There were fewer

papers that assessed CBF in MCI compared to CN, but relatively decreased CBF in MCI was reported in all regions except for the thalamus, and relatively increased CBF in MCI was reported in the frontal and temporal lobes, hippocampus, and thalamus.

In terms of the number of studies that reported each finding, decreased CBF in AD was reported in the frontal lobe in 18 papers, in the parietal lobe in 20 papers, in the temporal lobe in 19 papers, in temporoparietal regions in 10 papers, in the occipital lobe in nine papers, in the posterior cingulate in nine papers, in the hippocampus in three papers, and in the thalamus in five papers. Relative increases in CBF in AD were reported in the frontal lobe in three papers, in the temporal lobe in one paper, in the hippocampus in one paper, and in the thalamus in two papers.

Relative decreases in CBF in MCI were reported in the frontal lobe in one paper, in the parietal lobe in one paper, in the temporal lobe in three papers, in the temporoparietal region in one paper, in the occipital lobe in one paper, in the posterior cingulate in three papers, and in the hippocampus in one paper. Relative increases in CBF in MCI were reported in the parietal lobe in two papers, in the temporal lobe in one paper, in the hippocampus in one paper, and in the thalamus in one paper. These results include reports of altered CBF that were not statistically significant in the original papers.

Of the papers that assessed the relationship between cognitive test scores and CBF, a majority of them reported a positive correlation, but there were also reports of negative correlations and of no correlation. Specifically, a positive correlation between regional CBF and cognitive function was reported in nine papers. The cognitive tests used in these papers include the Mini Mental State Examination, 15- Objects Test, 15 item Boston Naming Test, Poppelreuter test, Cognitive Capacity Screening Examination, Cambridge Cognition Examination (CAMCOG; language, praxis, and abstraction sub-scores), Mini Mental State Questionnaire,

Trail Making Test Part B, and the Clock Drawing Test. A negative correlation between regional CBF and scores on the Trail Making Test Part B was reported in one paper. One paper reported no correlation between global CBF and revised CAMCOG scores when other independent variables were in the model, and another paper reported no correlation between regional CBF and the memory sub-score of the CAMCOG. One paper reported no correlation between regional CBF and the California Verbal Learning Test or Self-Ordering Test. Additionally, two papers reported a mix of positive and negative correlations between regional CBF and cognitive test scores.

Figure 2 and Supplementary Figure 1 graphically present the Hedge's  $g$  score and 95% confidence interval for the difference in CBF between AD and CN (Figure 2) and between MCI and CN (Supplementary Figure 1) for each brain region. Positive values represent relatively decreased CBF in MCI/AD. Alegret et al. (2010) reported regional CBF as mean (SD) of eigenvariates from voxel-wise comparisons, which are not directly comparable to the other results, but are included in these graphs for completeness.

Table 3 is a Summary of Findings table for the syntheses of results. Results are presented for CBF in CN vs. AD in papers that reported regional CBF values as mean (SD). Seventeen papers were included. Alegret et al. (2010) was not included. Encinas et al. (2003) was also not included because there was no CN group in that study. Table 3 reports combined sample size, number of studies included, authors of included studies, mean, median, and range of Hedge's  $g$  scores, certainty, and comments for syntheses of CBF in AD relative to controls in each brain region. The region with the greatest mean Hedge's  $g$  (greatest relative decrease in CBF in AD) is the temporoparietal ( $g = 1.67$ ), followed by the posterior cingulate ( $g = 1.34$ ). All regions had positive mean and median Hedge's  $g$  scores (decreased relative CBF in AD). At least one paper

reported an increase in CBF in AD compared to CN in the frontal lobe, temporal lobe, and the hippocampus.

Reporting bias was assessed by rating the completeness of each paper in the syntheses. All papers that reported mean and SD CBF values for AD and CN were included except for Alegret et al. (2010) due to this paper's use of voxel-wise eigenvariates. Of the included papers, Firbank et al. (2011) was missing CBF data from the thalamus for one CN participant, and Schuff et al. (2009) did not analyze or report occipital CBF data because too few voxels were present after selecting only "pure" gray or white matter voxels. Otherwise, results were fully reported in all papers. Papers were also included in regional syntheses if they reported CBF values for relevant subregions, some of which we combined for an average value within the synthesis region. This review only includes published articles from PubMed that were in English and fully accessible. These restrictions contribute to a moderate level of reporting bias, but reporting bias is likely not increased from other sources or for other reasons.

Certainty of syntheses was rated based on cumulative risk of bias scores of the constituent papers; if the weighted average risk of bias score (based on sample size) was less than "fair," the overall certainty was lowered. Certainty was also lowered due to inconsistency (scores were higher if all results were in the same direction), and indirectness and/or imprecision (including papers where we combined subregions' values, subgroups, or where we extracted data from graphs). Large effect sizes, evidence of dose-response relationships (MCI values intermediate between CN and AD values), and confounding factors that would have likely resulted in an effect of the opposite direction were considered as reasons to raise or maintain the certainty score. Justifications for the certainty score are included in detail in Table 3 for each synthesis.

## DISCUSSION

In this systematic review, we compiled findings of altered CBF in MCI/AD from previously published literature. There were consistent reports of decreased CBF in AD compared to CN in parietal, temporoparietal, occipital, and posterior cingulate regions. Frontal, temporal, hippocampal, and thalamic regions each had either increases in CBF in AD or no differences reported in at least one paper. Interestingly, thalamic CBF was relatively decreased in AD in all five papers that reported regional CBF and relatively increased in the two papers that reported voxel-wise results. The greatest relative decrease in CBF in AD was in the temporoparietal and posterior cingulate regions. Across regions, 93% of the results reported decreased CBF in AD compared to CN. For CBF in MCI compared to CN, the results were mixed. Only five papers reported regional or voxel-wise comparisons in CBF between CN and MCI, but of the 16 regional results, 5 (31%) of them reported increased CBF in MCI compared to CN. The higher percentage of brain regions with relatively increased CBF in MCI may be because there were fewer papers that compared CBF between MCI and CN. However, it has been suggested that increased CBF in MCI could be a compensatory response to early AD pathology, in which increased blood flow is necessary in order to function at a normal level. In Zhang et al. (2021), the authors concluded that decreased CBF begins in the posterior cingulate, temporoparietal, and thalamic regions during MCI and that decreased CBF becomes more widespread in AD. We found some evidence of decreased CBF in MCI and reported MCI values that were intermediate between CN and AD values (Alegret et al., 2010; Dai et al., 2009). We also found that the greatest relative decreases in CBF in AD were located in the temporoparietal region and the posterior cingulate. Both of these regions have been reported to have decreased CBF and decreased glucose metabolism in previous studies and reviews, and these alterations are

considered characteristic of AD (Matsuda, 2001). The reasons for this pattern may be due to the spatial spread of tau pathology during AD, to vulnerability of these areas to vascular and/ or neuronal damage, or to damage of functionally connected brain regions. Like Zhang et al. (2021), we found quite consistent findings of positive correlations between regional CBF and cognitive functioning, which supports the idea that decreased CBF is associated with cognitive impairment in AD. It will be necessary for future studies to elucidate whether transient increases in CBF during MCI are characteristic of this stage of disease or if this only occurs in a particular subset of individuals with MCI.

Another finding from this review is that only a few papers comparing CBF between diagnostic stages accounted for potential confounding variables other than age in the analyses. Nearly all papers accounted for the potential effect of age on CBF by using diagnostic groups that did not differ by age. Sundstrom et al. (2006) reported that the CN group was younger than the AD group. The only paper that did not report adequate information about group age was Mubrin et al. (1989). Neither of these papers were included in the syntheses presented in the Summary of Findings Table. Aside from age, three papers included sex as a covariate, one paper included the presence of hypertension, one paper included white matter lesion volume, one paper included the presence of the *APOE*  $\epsilon 4$  allele, one paper included body mass index, and one paper included cerebral glucose metabolism. These factors and others, including other cardiovascular risk factors, lifestyle factors, and possibly socioeconomic factors could potentially have an effect on CBF and/or cognitive function, and they should be taken into account in future studies of CBF in AD.

One of the limitations of this review is that we included only accessible articles from PubMed that were published in English. Another limitation inherent to this review is the

inclusion of articles across various decades, in which several different imaging and processing methods were used to measure CBF. Papers also used different reference regions to normalize the CBF values. Despite this, the results of CBF in AD compared to CN and of CBF in relation to cognitive test scores were generally consistent. The less consistent results in the MCI group may be due to the small sample size or may be due to differences that were not accounted for in the MCI samples. Additionally, this review only includes papers with AD samples in a specific age range, so the number of papers included is relatively small, and some of them have small sample sizes. Due to these limitations and to the observational and correlational nature of the research question, the results and syntheses presented here are meant to summarize and consolidate the existing evidence of altered CBF in MCI/AD and to characterize general patterns in these findings, rather than to make conclusive statements about the degree of these changes.

## CONCLUSIONS

The results of this review suggest that more research is needed to better understand the spatial and temporal nature of changes in CBF throughout the course of AD, especially in early stages of disease including MCI. In addition, standardization of methods to measure and process CBF would allow results from different studies to be more easily consolidated or compared. We believe that to best characterize CBF for its potential use as an early noninvasive biomarker for AD, large and diverse samples of participants must be employed so that analyses can be completed in multiple brain regions and with multiple factors included as covariates.

Longitudinal studies that meet these criteria and include individuals from different disease stages will likely help to clarify the specific patterns of altered CBF that are usually present during the

years leading up to a diagnosis of AD, as well as determine how alterations in CBF relate to AD pathologies and cognitive decline.

## Author Contributions

Author contributions included conceptual and study design (CGS, SLR and AJS), literature search and selection of included publications (CGS), summarization, synthesis, and presentation of results (CGS), interpretations, conclusions, and overall messaging (all authors), and comments, revisions, and approval for final publication (all authors).

## Funding Sources

Dr. Risacher receives support from the National Institute on Aging (K01 AG049050, R01 AG061788) and the New Vision Award. Dr. Wu receives support from the National Institute on Aging (R01 AG053993). Dr. Apostolova receives support from NIH, Alzheimer Association, AVID Pharmaceuticals, Life Molecular Imaging, and Roche Diagnostics. Dr. Saykin receives support from multiple NIH grants (P30 AG010133, P30 AG072976, R01 AG019771, R01 AG057739, U01 AG024904, R01 LM013463, R01 AG068193, T32 AG071444, and U01 AG068057 and U01 AG072177). He has also received support from Avid Radiopharmaceuticals, a subsidiary of Eli Lilly (in kind contribution of PET tracer precursor).

## Conflict of Interest

Dr. Apostolova receives support in the form of consulting fees from Biogen, Two Labs, IQVIA, NIH, Florida Department of Health, NIH Biobank, Eli Lilly, GE Healthcare, and Eisai; in the form of payment for lectures, etc. from AAN, MillerMed, AiSM, and Health and Hospitality; and in the form of travel and meeting support from Alzheimer's Association. She also participates on Data Safety Monitoring or Advisory boards for IQVIA, NIA R01 AG061111, UAB Nathan Shock Center, and New Mexico Exploratory ADRC; in leadership roles for Medical Science Council Alzheimer Association Greater IN Chapter, Alzheimer Association Science Program Committee, and FDA PCNS Advisory Committee; stock or stock options Cassava Neurosciences and Golden Seeds, and receipt of materials, etc. from AVID Pharmaceuticals, Life Molecular Imaging, and Roche Diagnostics. Dr. Saykin serves with Bayer Oncology (Scientific Advisory Board), Eisai (Scientific Advisory Board), Siemens Medical Solutions USA, Inc. (Dementia Advisory Board), and Springer-Nature Publishing (Editorial Office Support as Editor-in-Chief, Brain Imaging and Behavior). All other authors report no disclosures.

## Data Availability Statement

We did not analyze or generate datasets because this work involved the compilation and synthesis of previously published results, all of which are cited and available to view.

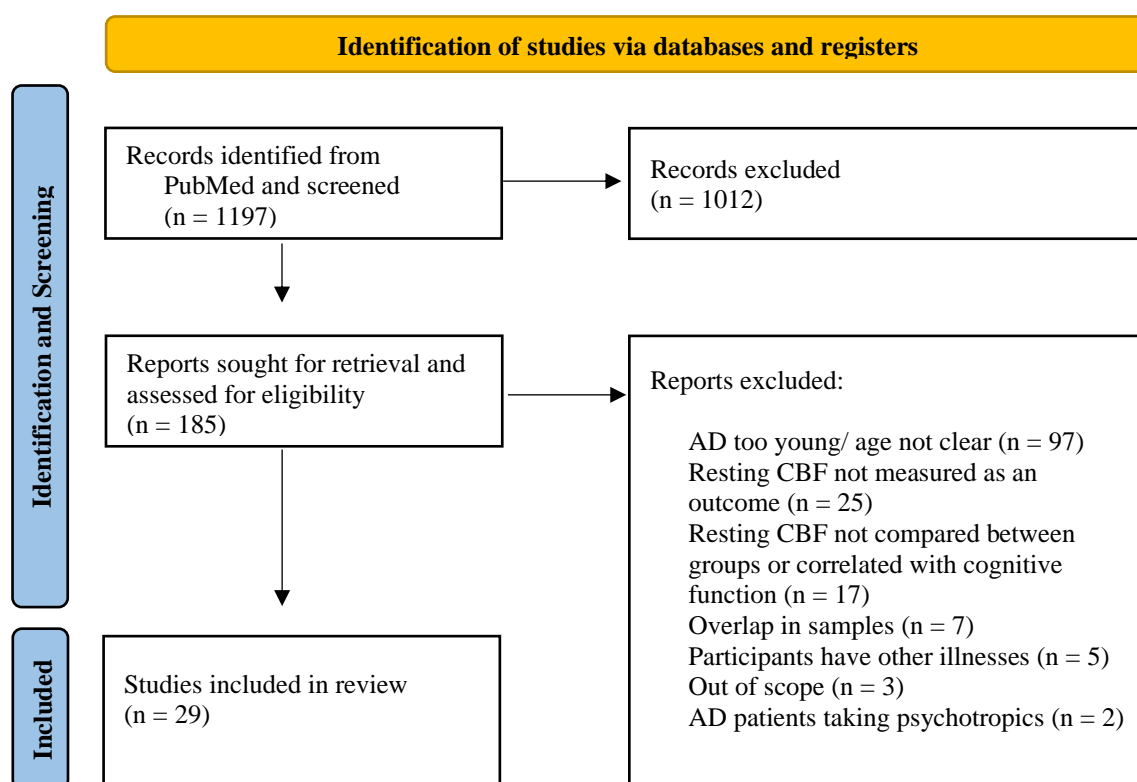

Figure 1. PRISMA flow chart of articles identified, assessed for eligibility, and included in systematic review. Reasons for exclusion are listed. Included papers compare resting CBF between AD/MCI and CN, include an AD sample where over 95% are 60 years old or older, and are written in English.

Supplementary Figure 1. Effect sizes and 95% confidence intervals of difference in CBF between MCI and CN in frontal lobe (A), parietal lobe (B), temporal lobe (C), temporoparietal region (D), posterior cingulate (E), hippocampus (F), and thalamus (G). Positive effect sizes indicate that CBF is decreased in MCI relative to CN.

Table 1. Risk of bias assessment scores for included articles.

Authors	Clearly Stated Objective	Clearly Defined Sample	Controls and Cases from same Population	Same Inclusion Criteria for Controls and Cases	Clear Distinction of Cases and Controls	Reliable Methods to Measure CBF	Blind Assessment of CBF	Con-founding Variables	Score and Justification
Alegret et al.	yes	no	yes	no	yes	yes	not applicable	yes	fair; little information about samples; AD group were all taking AChEIs while the other groups were not, and most CN did not have CT to check for exclusions
Benoit et al.	yes	yes	no	not reported	not reported	yes for AD; not reported for CN	not applicable	no	poor; CN are from a different population, scanned separately but “similarly”, not clear whether the inclusion criteria is the same, and cognitive scores for the CN group are not reported
Brown et al.	yes	no	yes	yes	yes	yes	yes	no	good
Claus et al.	yes	yes	no	yes	yes	yes	yes	yes	good
Dai et al.	yes	yes	yes	yes	yes	yes	not applicable	yes	good
Ding et al.	yes	yes	not reported	yes	yes	yes	not applicable	no	fair; it is not reported whether the groups are from the same population; only CN are excluded for substance abuse
Encinas et al.	yes	yes	yes	yes	yes	yes	yes	no	good
Firbank et al.	yes	no	not reported	not reported	yes	yes	yes	no	fair; little information about sample; unclear whether population and/or inclusion criteria are the same between groups
Hanyu et al. 2004	yes	no	not reported	no	yes	yes	not applicable	no	fair; it is not clear whether the groups are from the same population; only AD are excluded based on cerebrovascular lesions
Hanyu et al. 2008	yes	yes for cases,	not reported	not reported	not reported	yes	not applicable	no	poor; essentially no information reported about CN group;

		no for controls							unclear whether groups come from the same population or have the same inclusion criteria; no cognitive exam scores reported for CN
Harris et al.	yes	yes	yes	yes	yes	yes	yes	no	good
Iizuka & Kameyama	yes	yes for cases, no for controls	not reported	not reported	yes	yes	not applicable	no	fair; it is not clear whether the groups are from the same population; only AD are excluded for taking anti-anxiety or antidepressant medications
Jagust et al.	yes	no	yes	yes	not reported	yes	not reported	no	poor; while not explicitly clear, it can be deduced that groups are from the same population; inclusion criteria appears to be the same; cognitive exam scores are not reported for CN
Johnson et al.	yes	no	yes for the MCI at baseline; unknown for AD	yes	yes	yes	not applicable	no	fair; not clear whether the AD are from the same population as the MCI at baseline. Inclusion criteria is also not applied to several MCI, who are younger than the reported 65 year cutoff
Kimura et al.	yes	yes for cases, no for controls	not reported	yes	yes	yes	not applicable	no	fair; little information about the CN group; not clear if they are from the same population as AD
Lacalle-Aurioles et al.	yes	yes	yes	yes	yes	yes	yes	no	good
Lee et al.	yes	no	not reported	not reported	yes	yes	not applicable	no	fair; little information given about the sample, not clear whether the groups are from the same population or if they have the same inclusion criteria

Mubrin et al.	yes	no	not reported	not reported	not reported	yes for imaging; not reported for processing	not reported	no	poor; very little information about samples, especially CN; CN does not have cognitive scores reported
Nagahama et al.	yes	yes for cases, no for controls	not reported	yes	not reported	yes	not applicable	no	poor; little information about CN, not sure if they are from the same population as AD; cognitive scores not reported for CN
Obara et al.	yes	no	not reported	no	yes	yes	not reported	yes	fair; little information about sample; not sure whether groups are from the same population; inclusion criteria differs slightly between groups
Sase et al.	yes	yes	yes	no	yes	yes	not applicable	no	fair; inclusion criteria differs slightly between groups
Schuff et al.	yes	yes	yes	yes	yes	yes	not applicable	yes	good
Shimizu et al.	yes	yes for cases, no for controls	not reported	no	not reported	yes	not applicable	no	poor; not reported whether the groups are from the same population; only AD are excluded for taking medication that affects the CNS; cognitive exam scores are not reported for CN
Sundström et al.	yes	yes	yes	yes	yes	yes	not applicable	no	poor; CN are younger than AD
Takahashi et al.	yes	yes	yes	yes	yes	yes	not applicable	no	good
Tateno et al.	yes	no	not reported	no	yes	yes	not applicable	no	fair; little information given about the sample, not clear whether the groups are from the same population; only CN have abnormalities on scans as exclusion criteria
van de Haar et al.	yes	yes	yes	no	not reported	yes	yes	yes	fair; only AD are excluded for history of stroke; CN are said

									to complete cognitive exams, but their scores are not reported
Yew & Nation	yes	yes	yes	yes	yes	yes	not applicable	yes	good
Yoshida et al.	yes	yes	yes	no	yes	yes	yes	no	fair; inclusion criteria are not the same: all AD have <i>APOE</i> ε4, but this is not reported for CN

AD: Alzheimer's disease, AchEI: acetyl cholinesterase inhibitor, *APOE*: apolipoprotein E, CBF: cerebral blood flow, CN: cognitively normal, CNS: central nervous system, CT: computed tomography, MCI: mild cognitive impairment

Table 2. CBF in CN and AD in each paper.

Author	Sample Size	Frontal	Parietal	Temporal	Temporo-parietal	Occipital	Posterior Cingulate	Hippo-campus	Thalamus	Notes
Alegret et al.	CN: 42 AD: 42			AD < CN  CN: 667 (25) AD: 504 (26)	AD < CN  CN: 1028 (25) AD: 802 (24)		AD < CN  CN: 885 (20) AD: 696 (26)	AD < CN  CN: 716 (23) AD: 535 (22)		Values are eigenvariates from peak voxels where CBF differs between groups; SDs are adjusted for age; data extracted from bar graph. Regions are temporal: left temporal lobe and right temporal pole, temporoparietal: right angular gyrus, and right hippocampus.
Benoit et al.	CN: 11 AD: 30	AD < CN  z = 3.79 k = 1322 p = 0.008					AD < CN  z = 3.25 k = 1431 p = 0.005			Results are from comparison of the whole AD group (with and without apathy) and CN; voxels correspond to right medial frontal and right posterior cingulate regions.
Brown et al.	CN: 14 AD: 24	AD < CN  CN: 0.854 (0.040) AD: 0.796 (0.086)	AD < CN  CN: 0.890 (0.046) AD: 0.764 (0.104)	AD < CN  CN: 0.917 (0.050) AD: 0.839 (0.077)						Values are regional CBF normalized to calcarine cortex; regions are frontal: low frontal & high frontal; temporal: temporal & posterior temporal; data extracted from bar graph; significance reported with Bonferroni correction
Claus et al.	CN: 60 AD: 48	AD < CN CN: 84.3 (5.6) AD: 80.8 (6.3)		AD < CN  CN: 83.0 (5.2) AD: 76.0 (7.1)	AD < CN  CN: 78.4 (6.8) AD: 70.5 (9.8)	AD < CN  CN: 89.2 (6.1) AD: 86.5 (6.4)				Values are percentages of regional CBF relative to cerebellar CBF; anatomical ROI multi-slice values used.
Dai et al.	CN: 38 AD: 37	AD < CN  CN: 52.6 (18.1)	AD < CN  CN: 53.1 (19.4)	AD < CN  CN: 51.1 (18.9) AD: 36.0 (8.7)			AD < CN  CN: 61.2 (20.5) AD: 46.4 (15.9)	AD > CN  CN: 42.1 (10.2)	AD < CN  CN: 45.2 (18.8) AD: 36.9 (19.7)	Regions are frontal: left lateral frontal and left orbitofrontal, parietal: left interior and left superior

		AD: 37.0 (11.6)	AD: 38.4 (13.2)					AD: 42.7 (13.0)		parietal, and temporal: left superior temporal.
Ding et al.	CN: 21 AD: 24	AD > CN  t = - 3.95 k = 312 p < 0.01	AD < CN  t = 3.34 k = 391 p < 0.01	AD < CN  t = 3.33 k = 340 p < 0.01		AD < CN  t = 4.77 k = 2569 p < 0.01			AD > CN  t = -3.32 k = 355 p < 0.01	Voxels are: right paracentral, right superior parietal, right middle & inferior temporal, left superior, middle & inferior occipital & cuneus, and left thalamus
Encinas et al.	stable MCI: 21 MCI progress ing to AD: 21	AD < MCI  MCI: 89.8 (10) AD: 80.8 (7.8)	AD < MCI  MCI: 90.0 (8.6) AD: 82.0 (8.5)	AD < MCI  MCI: 85.0 (9.4) AD: 76.0 (9.0)	AD < MCI  MCI: 87.5 (9.1) AD: 79.5 (7.5)					Values are percentage of regional CBF over cerebellar CBF; comparisons are stable MCI vs. MCI that progress to AD, at baseline; frontal: right and left prefrontal, right and left frontal; parietal: right and left parietal; temporal: right and left temporal, left posterior lateral temporal; temporoparietal: right and left frontoparietotempor al
Firbank et al.	CN: 29 AD: 17	AD < CN  CN: 1.82 (0.27) AD: 1.58 (0.28)	AD < CN  CN: 1.70 (0.32) AD: 1.34 (0.31)			AD < CN  CN: 1.55 (0.27) AD: 1.47 (0.29)			AD < CN  CN: 2.68 (1.08) AD: 2.28 (0.71)	Values are GM:WM ratio; one control does not have data for thalamus; statistics are Gabriel post hoc tests; frontal: prefrontal.
Hanyu et al. 2004	CN: 22 AD: 22	AD < CN AD: 1.04 (0.47)			AD < CN AD: 1.48 (0.55)	AD < CN AD: 0.95 (0.51)	AD < CN AD: 1.2 (0.5)			Values are z scores normalized to CN values
Hanyu et al. 2008	CN: 28 AD: 53	AD < CN  AD: 0.98 (0.55)	AD < CN  AD: 1.20 (0.70)	AD < CN  AD: 0.98 (0.61)	AD < CN  AD: 1.43 (1.07)	AD < CN  AD: 0.77 (0.77)	AD < CN  AD: 0.99 (0.52)		AD < CN  AD: 0.46 (0.47)	Values are z scores normalized to CN values; combined high and low education AD groups; frontal: superior, middle, inferior, medial, orbital frontal;

										parietal: superior and inferior parietal; temporal: superior, middle, inferior, and transverse temporal; temporoparietal: supramarginal and angular gyri; occipital: superior, middle, and inferior occipital.
Harris et al.	CN: 8 AD: 15	AD < CN  CN: 101.6 (8.8) AD: 91.7 (10.7)			AD < CN  CN: 105.8 (8.2) AD: 89.4 (11.9)	AD < CN  CN: 106.0 (8.9) AD: 97.6 (11.3)				All regions are combined from two slices: at basal ganglia level and superior to it
Iizuka & Kameyama.	CN: 9 AD: 36	AD < CN	AD < CN	AD < CN			AD < CN			Results were qualitative in the text and presented in a brain surface figure with a color scale, but it was not feasible to accurately extract values based on color. Comparisons were at baseline and were present in CN vs. responding and/or nonresponding AD before treatment began.
Jagust et al.	CN: 5 AD: 9	AD > CN  CN: 1.11 (0.09) AD: 1.16 (0.08)			AD < CN  CN: 1.10 (0.05) AD: 0.93 (0.04)					Values are regional CBF over whole tomographic slice
Johnson et al.	CN: 19 AD: 34	AD < CN z = 3.59 k = 214	AD < CN z = 5.20 k = 6629 corr. p < 0.05	AD < CN z = 4.01 k = 2117 corr. p < 0.05			AD < CN  z = 4.87 k = 862 corr. p < 0.05		AD > CN  z = -4.42 k = 1184 corr. p < 0.05	Voxels are located in: left inferior frontal, left inferior parietal, right superior temporal, right posterior cingulate, and left

		corr. p < 0.05								thalamus & striatum; p values are corrected for multiple comparisons.
Kimura et al.	CN: 27 AD: 62		AD < CN  CN: 35.4 (4.3) AD: 30.5 (5.2)	AD < CN  CN: 35.3 (3.6) AD: 30.8 (4.7)	AD < CN  CN: 40.4 (4.6) AD: 34.5 (5.9)		AD < CN  CN: 41.3 (5.1) AD: 35.9 (5.5)			Regions are: left superior and inferior parietal, left and right middle and inferior temporal, right angular gyrus, and left and right posterior cingulate
Lacalle- Auriol s et al.	CN: 20 AD: 28		AD < CN  CN: 0.849 (0.032) AD: 0.812 (0.051)	AD > CN  CN: 0.778 (0.063) AD: 0.828 (0.069)						Values are regional CBF over whole cortical GM CBF; data was extracted from graphs; regions are: left and right parietal lobe, right medial temporal lobe.
Lee et al.	CN: 20 AD: 20	AD < CN  z = 4.64 corr. p = 0.007	AD < CN  z = 6.87 corr. p < 0.001	AD < CN  z = 6.94 corr. p < 0.001						Used moderate AD as the AD group; voxels come from: left middle frontal, right superior parietal, and right superior temporal; cluster sizes not reported; p values corrected for multiple testing.
Mubrin et al.	CN: not clear AD: 31		AD < CN		AD < CN					Results are qualitative only; both regions are bilateral.
Obara et al.	CN: 18 AD: 17	AD < CN  CN: 42.3 (9.4) AD: 37.5 (4.4)	AD < CN  CN: 43.1 (6.9) AD: 37.7 (4.9)	AD < CN  CN: 43.1 (7.6) AD: 38.2 (6.1)		AD < CN  CN: 39.5 (8.8) AD: 35.9 (4.7)			AD < CN  CN: 51.8 (10.7) AD: 47.0 (9.4)	
Sase et al.	CN: 15 AD: 27									This paper measures CBF in 5 mm layers from the surface of the brain. AD < CN in cingulate cortex and in every layer measured; measurements of

										layers were taken from lateral, superior, anterior, and posterior views. The greatest differences were found in the left lateral view of the third and fourth layers.
Schuff et al.	CN: 18 AD: 14	AD < CN CN: 56.4 (7.9) AD: 41.2 (10.9)	AD < CN CN: 58.7 (9.8) AD: 43.6 (11.7)	AD < CN CN: 52.7 (19.1) AD: 45.5 (15.2)

Sundström et al.	CN: 18 AD: 18	AD < CN	AD < CN	AD < CN						Voxel-wise comparison are presented graphically but not numerically; frontal region is mainly middle frontal
Tateno et al.	CN: 16 AD: 38		AD < CN CN: 42.2 (3.5) AD: 37.2 (3.9)	AD < CN CN: 36.8 (5.3) AD: 33.7 (4.1)	AD < CN CN: 45.2 (4.0) AD: 38.5 (4.9)			AD < CN CN: 30.4 (5.2) AD: 26.3 (3.1)	AD < CN CN: 39.3 (7.2) AD: 34.4 (5.7)	Values were extracted from bar graphs; the temporoparietal data is from the angular gyrus
van de Haar et al.	CN: 16 MCI/A D: 14	MCI/A D < CN  CN: 38.9 (7.2) MCI/A D: 33.3 (7.6)	MCI/A D < CN  CN: 39.6 (6.7) MCI/A D: 32.4 (7.4)	MCI/AD < CN  CN: 36.8 (6.2) MCI/AD: 31.1 (7.6)		MCI/AD < CN  CN: 37.9 (8.3) MCI/AD: 30.7 (9.1)				The AD group includes MCI
Yew & Nation	CN: 87 AD: 33	AD < CN	AD < CN	AD < CN CN: 23.4 (5.2)				AD < CN		The CN are amyloid-positive; data extracted from bar graph; regions

		CN: 23.2 (3.7) AD: 21.5 (6.2)	CN: 30.2 (4.7) AD: 26.3 (7.5)	AD: 21.4 (7.5)				CN: 28.0 (5.2) AD: 24.7 (6.9)		are frontal: medial orbital and rostral middle frontal, inferior temporal, and inferior parietal
Yoshida et al.	CN: 8 AD: 8	AD > CN CN: 0.80 (0.06) AD: 0.82 (0.09)	AD < CN CN: 0.84 (0.08) AD: 0.79 (0.11)	AD < CN CN: 0.76 (0.03) AD: 0.63 (0.11)			AD < CN CN: 0.84 (0.11) AD: 0.60 (0.11)			Values are regional CBF: occipital cortex CBF ratios; the temporal region is the medial temporal lobe.

AD: Alzheimer's disease, CBF: cerebral blood flow, CN: cognitively normal, GM: grey matter, MCI: mild cognitive impairment, ROI: region of interest, SD: standard deviation, WM: white matter

Table 3. Syntheses of CBF in AD compared to CN by brain region.

Brain Region	Individuals	Studies	Hedge's G; Mean, Median and Range	Certainty	Comments
Frontal	386 cases; 379 controls	14: Brown et al., Claus et al., Dai et al., Firbank et al., Hanyu et al. 2004, Hanyu et al. 2008, Harris et al., Jagust et al., Obara et al., Schuff et al., Shimizu et al., van de Haar et al., Yew and Nation, Yoshida et al.	0.79; 0.82 (-0.56, 1.79)	low	Certainty lowered because: data extracted from graphs (Brown et al., Jagust et al., Yew and Nation), several subregions and high and low education groups combined in Hanyu et al. 2008, subregions combined in Brown et al., Harris et al.; Notes: two papers with increase in AD (Jagust et al. and Yoshida et al.) have very small sample sizes, van de Haar et al. has MCI in AD group and Yew and Nation has MCI in CN group. All AD in Yoshida et al. are <i>APOE</i> ε4 positive.
Parietal	420 cases; 347 controls	13: Brown et al., Dai et al., Firbank et al., Hanyu et al. 2008, Kimura et al., Lacalle-Aurioles et al., Obara et al., Schuff et al., Shimizu et al., Tateno et al., van de Haar et al., Yew and Nation, Yoshida et al.	1.11; 1.00 (0.49, 1.97)	moderate	Certainty lowered because: data extracted from graphs (Brown et al., Lacalle-Aurioles et al., Tateno et al., Yew and Nation), several subregions and high and low education groups combined in Hanyu et al. 2008, subregions combined in Brown et al. Notes: van de Haar et al. has MCI in AD group and Yew and Nation has MCI in CN group, all AD in Yoshida et al. are <i>APOE</i> ε4 positive.
Temporal	451 cases; 378 controls	13: Brown et al., Claus et al., Dai et al., Hanyu et al. 2008, Kimura et al., Lacalle-Aurioles et al., Obara et al., Schuff et al., Shimizu et al., Tateno et al., van de Haar et al., Yew and Nation, Yoshida et al.	0.85; 1.01 (-0.74, 1.83)	moderate	Certainty lowered because: data extracted from graphs (Brown et al., Lacalle-Aurioles et al., Tateno et al., Yew and Nation), several subregions and high and low education groups combined in Hanyu et al. 2008, subregions combined in Brown et al.; Notes: one paper with increase in AD (Lacalle-Aurioles et al.) shows same pattern to a lesser extent in MCI; van de Haar et al. has MCI in AD group and Yew and Nation has MCI in CN group, all AD in Yoshida et al. are <i>APOE</i> ε4 positive.
Temporoparietal	247 cases; 166 controls	7: Claus et al., Hanyu et al. 2004, Hanyu et al. 2008, Harris	1.67; 1.42 (0.95, 3.63)	moderate	Certainty lowered because: data extracted from graphs (Jagust et al., Tateno et al.), several subregions and high and low education groups

		et al., Jagust et al., Kimura et al., Tateno et al.			combined in Hanyu et al. 2008, subregions combined in Harris et al.; Notes: Jagust et al. had the largest effect size despite a small sample size, and this paper also showed a positive correlation between CBF and cognitive scores.
Occipital	261 cases; 209 controls	8: Claus et al., Firbank et al., Hanyu et al. 2004, Hanyu et al. 2008, Harris et al., Obara et al., Shimizu et al., van de Haar et al.	0.78; 0.79 (0.28, 1.41)	low	Certainty lowered due to low cumulative bias rating of constituent papers, several subregions and high and low education groups combined in Hanyu et al. 2008, subregions combined in Harris et al.; Notes: van de Haar et al. has MCI in AD group.
Posterior Cingulate	182 cases; 123 controls	5: Dai et al., Hanyu et al. 2004, Hanyu et al. 2008, Kimura et al., Yoshida et al.	1.34; 1.36 (0.80, 2.06)	low	Certainty lowered due to low cumulative bias rating of constituent papers, several subregions and high and low education groups combined in Hanyu et al. 2008; Notes: all AD in Yoshida et al. are <i>APOE</i> ε4 positive.
Hippocampus	108 cases; 141 controls	3: Dai et al., Tateno et al., Yew and Nation	0.53; 0.57 (-0.05, 1.06)	low	Certainty lowered because: data extracted from graphs (Tateno et al., Yew and Nation); Notes: one paper with increase in AD (Dai et al.) shows similar pattern in MCI, but the effect is very small in AD. Yew and Nation has MCI in CN group..
Thalamus	162 cases; 129 controls	5: Dai et al., Firbank et al., Hanyu et al. 2008, Obara et al., Tateno et al.	0.55; 0.46 (0.41, 0.78)	moderate	Certainty lowered due to low cumulative bias rating of constituent papers, data extracted from graphs (Tateno et al.), several subregions and high and low education groups combined in Hanyu et al. 2008; Notes: Firbank et al. is missing this region for one control.

AD: Alzheimer's disease, *APOE*: apolipoprotein E, CBF: cerebral blood flow, CN: cognitively normal, MCI: mild cognitive impairment

Supplementary Table 1. Characteristics of included articles.

Authors	Title	Publication Date	Location of Study/ Authors	Number of Participants and Diagnostic Groups	Criteria for Diagnoses	CBF Measurement Method	Ages by Diagnostic Group (mean [SD])	Results Included in Syntheses	Reports Relative CBF for AD	Reports Relative CBF for MCI	Reports Association between CBF and Cognitive Test Scores

Supplementary Table 2. CBF in CN and MCI in each paper.

Author	Sample Size	Frontal	Parietal	Temporal	Temporo-parietal	Occipital	Posterior Cingulate	Hippo-campus	Thalamus	Notes
Alegret et al.	CN: 42 MCI: 42			MCI < CN CN: 667 (25) MCI: 567 (26)	MCI < CN CN: 1028 (25) MCI: 874 (24)		MCI < CN CN: 885 (20) MCI: 739 (26)	AD < CN CN: 716 (23) MCI: 587 (26)		Values are eigenvariate s from peak voxels where CBF differs between CN and AD; SDs are adjusted for age; data extracted from bar graph. Regions are temporal: left temporal lobe and right temporal pole, temporoparietal: right angular gyrus, and right hippocampus.
Dai et al.	CN: 38 MCI: 29	MCI < CN CN: 52.6 (18.1) MCI: 50.5 (19.6)	MCI > CN CN: 53.1 (19.4) MCI: 53.4 (18.3)	MCI < CN CN: 51.1 (18.9) MCI: 44.8 (15.6)			MCI < CN CN: 61.2 (20.5) MCI: 47.7 (15.8)	MCI > CN CN: 42.1 (10.2) MCI: 59.6 (17.3)	MCI > CN CN: 45.2 (18.8) MCI: 54.6 (25.4)	Regions are frontal: left lateral frontal and left orbitofrontal, parietal: left interior and left superior parietal, and temporal: left superior temporal.
Ding et al.	CN: 21 MCI: 17		MCI < CN  t = 3.83 k = 298 p < 0.01	MCI < CN  t = 3.71 k = 363 p < 0.01		MCI < CN  t = 3.51 k = 350 p < 0.01				Voxels are from: right superior parietal lobule, right middle temporal gyrus, and left cuneus (occipital).

Johnson et al.	CN: 19 Decliners : 43						Decliners < CN z = 4.46 p < 0.02			CBF measured at baseline; decliners did not differ cognitively from CN at baseline, but their cognition declined over the following 4 years. Region is right posterior cingulate; cluster size not reported.
Lacalle-Auriolas et al.	CN: 20 MCI: 15		MCI > CN  CN: 0.849 (0.032) MCI: 0.855 (0.013)	MCI > CN  CN: 0.778 (0.063) MCI: 0.780 (0.020)						Values are regional CBF over whole cortical GM CBF; data was extracted from graphs; regions are: left and right parietal lobe, right medial temporal lobe.

AD: Alzheimer's disease, CBF: cerebral blood flow, CN: cognitively normal, GM: grey matter, MCI: mild cognitive impairment, SD: standard deviation

Supplementary Table 3. Relationships between CBF and cognition in each paper.

Authors	Sample Size	Correlation between CBF and Cognition	Notes
Alegret et al.	126 (CN, MCI, & AD)	CBF in posterior cingulate ( $r = 0.72$ , $p < 0.001$ ) and right temporal pole ( $r = 0.68$ , $p < 0.001$ ) is positively correlated with MMSE score. CBF in posterior cingulate ( $r = 0.55$ , $p < 0.001$ ) and right temporal pole ( $r = 0.48$ , $p < 0.001$ ) is positively correlated with 15-Objects Test score. CBF in posterior cingulate ( $r = 0.46$ , $p < 0.001$ ) and right temporal pole ( $r = 0.40$ , $p < 0.001$ ) is positively correlated with 15 item Boston Naming Test score. CBF in posterior cingulate ( $r = 0.37$ , $p < 0.001$ ) and right temporal pole ( $r = 0.34$ , $p < 0.001$ ) is positively correlated with Poppelreuter test score.	Relationship assessed across all participants; CBF measures are eigenvariates from the named regions.
Benoit et al.	30 AD (with and without apathy)	CBF in bilateral lateral parietal cortex is positively correlated with MMSE score. Significant clusters right: ( $z = 3.73$ , $p = 0.015$ ), left: ( $z = 3.64$ , $p = 0.010$ ).	Analysis was voxel-wise. Using the apathy score on the Neuropsychiatric Inventory as a covariate in the correlation did not change the results.
Brown et al.	24 AD	Longitudinal change in CAMCOG score is positively correlated with longitudinal change in CBF in right and left low frontal ( $r = 0.69$ ; $r = 0.74$ ) and right temporal regions ( $r = 0.62$ ). All $p < 0.05$ ; left low frontal $p < 0.05$ after Bonferroni correction.	Frontal and temporal CBF was positively correlated with language, praxis, and abstraction, but not memory CAMCOG sub-scores in this paper.
Firbank et al.	46 (CN and AD)	Global GM/WM CBF does not contribute to the variation in CAMCOG-R score when age, sex, and hippocampal volume are predictors in the model.	
Jagust et al.	9 AD	The ratio of CBF in the temporoparietal region: whole tomographic slice is positively correlated with MMSQ score ( $r = 0.81$ , $p < 0.01$ ).	
Johnson et al.	124 CN/ MCI	CBF in rostral anterior cingulate and inferior frontal regions was positively correlated with scores on Trailmaking Test Part B ( $p < 0.05$ ), while CBF in caudal anterior cingulate was negatively correlated with scores on the same test ( $p < 0.006$ ). No correlations were seen between anterior cingulate CBF and the California Verbal Learning Test or Self-Ordering Test, or between posterior cingulate CBF and any of the three tests.	
Nagahama et al.	28 AD, both rapidly and slowly progressing	CBF in right middle ( $z = 4.67$ , $k = 458$ , $p < 0.001$ ) and superior frontal gyrus ( $z = 3.05$ , $k = 8$ , $p < 0.01$ ) and right inferior parietal cortex ( $z = 3.27$ , $k = 332$ , $p < 0.001$ ) is decreased in patients that decline rapidly compared to those that decline slowly, meaning that their MMSE score declines less than 4 points over 2 to 3 years of follow-up.	Results reported from voxel-wise analysis.
Obara et al.	17 AD	Declines in parietal cortical CBF add to the prediction of cognitive decline on the CCSE ( $p = 0.015$ ) when other predictors are decline in cortical volumes and decline in subcortical densities.	CBF, cognition, and tissue volumes and densities were measured every 6 to 12 months for

			between 2 and 3 years on average.
Sase et al.	42 (CN and AD)	CBF: lambda ratio in the third ( $r = 0.66$ , $p < 0.0001$ ) and fourth ( $r = 0.68$ , $p < 0.0001$ ) layer left lateral views is positively correlated with MMSE scores.	Lambda is the Xenon solubility coefficient. CBF and CBF:lambda ratio were decreased in AD compared to CN in this paper.
Takahashi et al.	25 (CN, MCI, and AD)	Clock Drawing Test scores are positively correlated with CBF in the left hippocampus ( $\rho = 0.43$ , $p < 0.05$ ), left parietal ( $\rho = 0.37$ ), bilateral pericallosal ( $\rho = 0.35$ ; $0.32$ ), and bilateral angular regions ( $\rho = 0.38$ ; $0.35$ ).	Correlation coefficients are Spearman's rho. Those without p values did not reach significance. Areas that with correlations less than $\rho = 0.32$ were: callosomarginal, precentral, central, right parietal, temporal, posterior, lenticular nucleus, thalamus, right hippocampus, and cerebellum.

AD: Alzheimer's disease, CAMCOG: Cambridge Cognitive Examination, CAMCOG-R: CAMCOG Revised, CBF: cerebral blood flow, CCSE: Cognitive Capacity Screening Examination, CN: cognitively normal, GM: grey matter, MCI: mild cognitive impairment, MMSE: Mini-Mental State Exam, MMSQ: Mini-Mental State Questionnaire, WM: white matter
