23 Abstract

Background- Diverse socio-economic and cultural issues contribute to adverse health outcomes and increased mortality rates among rural Indian women across different age categories. The present study aims to comprehensively assess age-specific mortality rates and their temporal trends using a composite measure at the sub-national level for rural Indian females to capture cross-state differences.

Methods- A total of 19 states were included in the study to construct a composite age-specific mortality index for 2011 (base year) and 2018 (reference year) and examine the incremental changes in the index values across these years at the sub-national level in India. Sub-index values were calculated for each component age group and were subsequently used to compute the composite ASMR index using the geometric mean method. Based on the incremental changes, the performance of states was categorized into four different typologies.

Results- Improvement in mortality index scores in the 0-4 years age group was documented for all states. The mortality rates for the 60+ age group were recorded to be high for all states. Kerela emerged as the overall top performer in terms of mortality index scores, while Bihar and Jharkhand were at the bottom of the mortality index table. The overall mortality composite score has shown minor improvement from base year to reference year at all India level.

Conclusions- An overall reduction in the mortality rates of rural Indian women has been observed
over the years in India. The success of public health interventions to reduce the under-five
mortality rate is evident as the female rural mortality rates have reduced sizably for all states.
Nevertheless, there is still sizable scope for reducing mortality rates for other component age

groups. Additionally, there is a need to divert attention toward the female geriatric (60+ years)
population as the mortality rates are still high.

46 Introduction

Nearly 65% of the Indians predominantly reside in rural areas [1], and half of them fall below the 47 poverty line [2]. Several studies conducted in developing countries have indicated the presence of 48 a strong association between low socio-economic status, poor health, and inaccessible health care 49 facilities [3]. Due to the unfavorable socio-economic conditions, the rural population faces a 50 recurring struggle for survival and succumbs to it most of the time [4]. Disparities in the life span 51 of rural and urban inhabitants have also been documented by many studies globally [5–7]. It can 52 53 be explained by the disproportionate distribution of public resources toward healthcare in urban and rural areas, thus increasing the gap in terms of healthcare facilities [8]. The low investment in 54 the health infrastructure of rural areas leads to management issues, a shortage of dedicated cadre 55 of the health workforce, and insufficient training of healthcare workers, which contribute to poor 56 health services at large. The other factors accounting for poorer survival of rural residents include 57 inefficient illness management, remote and inaccessible healthcare facilities, lack of preventive 58 and screening measures, and low levels of knowledge and awareness [7]. 59

Significant health inequalities and disparities in health status are also seen within India, leading to differences in the mortality rates of vulnerable populations like women and children. These inequalities affect populations at the national and sub-national levels [9]. The discrepancies in the health status resulting in high mortality are majorly reported in the Empowered Action Group (EAG) states of India, which are socioeconomically backward and lag in the demographic transition [10]. Bihar, Madhya Pradesh, Jharkhand, Chhattisgarh, and Uttar Pradesh are the few EAG states and are usually found at the bottom of the tables in most of the developmental parameters [11]. The major reasons for the poor performances of these states, specifically in terms
of health outcomes and high mortality rates, include poverty, overpopulation, low literacy levels,
gender discrimination, and poor health infrastructure [12].

Though biological differences exist between the genders however [13]; the health outcome 70 differences and inequalities are more evident in the case of rural Indian women. Women face 71 diverse socio-economic and cultural issues attributed in terms of gender discrimination, such as 72 female infanticide, child marriage, dowry, domestic violence, lack of education, and unavailability 73 of proper sanitation and healthcare facilities [14–16]. These indicators contribute to adverse health 74 outcomes and increased mortality rates among rural women across different age categories [10]. 75 76 Various targeted public health programmes have been implemented to reduce mortality rates, especially in the EAG states. Age-specific interventions have also been launched to improve 77 nutrition among women [17] and reduce mortality, particularly among infants and under-five 78 79 children [18]. The programmes have successfully reduced mortality to a great extent, but the progress has been uneven. There is still a striking difference between the age-specific mortality 80 rates at the sub-national level in India, especially concerning women residing in rural areas [19,20]. 81

There is a gap in the literature on assessing differences in the Age-Specific Mortality Rates 82 (ASMR) pertaining to rural women across different Indian states. To the best of our knowledge, 83 no published study in India has been conducted to quantify and transform the age-specific 84 mortality values into a single composite value at the sub-national level, especially for rural 85 females. The present study addresses the lacuna by constructing age-specific mortality index for 86 four major component age groups and a composite 'Age-specific mortality index' for rural Indian 87 88 women at the sub-national and national levels for base and reference years to examine the temporal 89 changes, if any. The proposed composite measure includes mortality values of all component age

groups within its ambit to capture India's cross-state differences. In this backdrop, the specific 90 objectives of the study can be defined as follows; a) to comprehensively quantify the mortality 91 values at the sub-national level in India by constructing a composite age-specific mortality index 92 for rural Indian women using a rigorous methodology involving historical benchmark values for 93 mortality; b) to examine the incremental changes in mortality index scores from base year to 94 95 reference year at the sub-national level.; c) to map and categorize Indian states into not improved, least, moderately and highly improved classification based on the incremental changes of the 96 mortality index scores. Thus, examining the state-specific and age-specific determinants leading 97 98 to sizable mortality rates among rural Indian women is essential to address the health inequalities. The identification of determinants necessitates the assessment of age-specific mortality rates and 99 their temporal trends in quantifiable terms at the sub-national level for rural Indian females, which 100 101 forms the very rationale and aim of the present study.

102 Methods

103 A. Data source

The secondary data on age-specific mortality rates of states was extracted from Sample 104 Registration System (SRS) statistical reports available on the web portal of the office of 105 the Registrar General and Census Commissioner under the Indian Ministry of Home 106 Affairs. The Census of India generates data on population statistics, including vital 107 statistics and census [21]. A total of 19 states have been included in the study to construct 108 a composite age-specific mortality index for 2011 (base year) and 2018 (reference year) 109 and examine the incremental changes in the index values across these years at the sub-110 national level in India. 111

B. Components of Age-Specific Mortality Rate

Age-Specific Mortality Rate (ASMR) is a mortality rate confined to a particular age group [22]. The SRS statistical reports publish ASMR by sex and residence for four-component age groups, i.e., 0-4 years, 5-14years, 15-59 years, and 60 years and above. Since the present study aimed to construct a composite ASMR index for rural females, the data pertaining to all the aforementioned component age groups of rural females were extracted for the years commencing from 1971 to 2018 for the identification of benchmark values required for data normalization.

121 C.

C. Data cleaning

The extracted data was randomly chosen and rechecked to assess errors in data entry. Followed by that, the data was checked for the missing values. Out of 28 Indian states, the data was completely missing for 7 states, bringing the tally down to 21 states. Subsequently, data for two Indian states, namely; Uttarakhand, was available after 2014 and for Telangana for the year 2018 only. The historical values of these states were not available in the literature and thus, these states were excluded from the study.

128

D. Computation of composite Age-specific Mortality Index

129

i. Data normalization

The extracted ASMR data was normalized based on the standardized procedure by employing the 'Minimum-Maximum approach' used by international and national agencies and organizations to compute various composite indices [4-5]. Since the indicators in the study were negative in nature, where an actual lower value means better performance, therefore the values were normalized and scaled using the following formula [23]: -

136		Normalized value (N _i) = <u>Maximum value - Actual value (X_i) × 100</u>
137		Maximum value-Minimum value
138		The minimum and maximum values refer to the benchmark values identified using
139		the following procedure.
140	ii.	Identification of 'minimum and maximum' (benchmark values) using
141		historical data
142		The Census of India has been publishing annual SRS statistical reports since 2011,
143		before which these reports were published intermittently commencing from 1971.
144		The benchmark values were identified using historical ASMR values published in
145		SRS statistical reports from 1971 to 2018 for each component age group. The
146		historical data, being a crucial tool in statistical procedures, is the data often
147		disaggregated or in different measuring [25] units that have been preserved for a
148		long period [26] as it reflects information having substantial significance. Historical
149		data is mainly required to identify the thresholds, which are then used for data
150		normalization. For negative indicators like mortality, the maximum thresholds
151		should not be obtained from the data range for which the index has to be calculated
152		(2011 to 2018 in the present study) using the geometric mean approach [27,28]. The
153		rationale governing this principle is that despite having non-zero (positive) values
154		for the component/domains of the composite index, the entire index is rendered to
155		be zero in the event of a single domain registering a zero value (which is
156		transformed through normalization process explained above). The minimum and
157		maximum values (benchmarks) are given in the supplementary table (S1 Table).
158		

159

iii. Construction of composite Age-specific Mortality Index

The normalized value computed for the four component age groups reflects the sub-160 index values for these age groups, which were subsequently used to compute the 161 composite ASMR index using the geometric mean method. The geometric mean 162 method has the upper hand over other measures as it is less altered by extreme 163 values, is robust and thus maintains an overall balance in data distribution. Further, 164 it is a standardized technique for index construction adopted by reputed 165 international agencies/organizations, including United Nations Development 166 Programme (UNDP) [24,29] 167

168 The index scores range from 0-to 100 for each indicator. A higher index score 169 (closer to 100) indicates a lower ASMR value, and a lower index score (closer to 170 zero) indicates a higher ASMR value.

171 E. Incremental changes and classification of states into different typologies

Incremental change measures the change in the index score from 2011 (base year) to 2018 172 (reference year). The highest positive incremental change across all the component age 173 groups was 13.9, reported in the 60+ category. Based on the incremental changes, the states 174 are divided into four groups: 'Not improved' (<=0 incremental change), 'Least improved' 175 (0.01 to 3 points increase), 'Moderately improved' (3.01 to 6 points increase), and 'Highly 176 improved' (> 6 points increase). The categorization was done using the percentile method 177 (P₂₀ and P₄₀ determining cut off points for least improved and moderately improved, 178 respectively) and is based on the approach followed by the National Institution for 179 180 Transforming India (NITI Aayog-the apex public policy 'think tank' of the Government of India) for categorizing health index scores. 181

F. Data sharing and Ethical Considerations- The study is purely based on secondary data, 182 which is freely available to the general public. The study does not involve any interaction 183 with the participants/human subjects. Hence, ethical approval was not required for this 184 study. Further, the excel files depicting the normalized values and computed composite 185 index score for age-specific mortality rates for rural Indian women across different Indian 186 states have already been uploaded to the Mendeley data repository [30] 187 (https://data.mendeley.com/datasets/v5gskzj78x/1) and can be easily accessed by the 188 interested users/researchers/ academicians and alike. 189

190 **Results**

191 Descriptive characteristics of component age groups of ASMR for rural Indian women

The means of AMSR values of the four component age groups for each state were calculated for a span of 8 years (2011-2018) (**Table 1**). At the all-India level, the highest mean death rate (41.63 ± 0.42) for rural Indian females was observed for the 60+ age group, while the lowest was for the 5-14 years age group (0.15 ± 0.08). In three out of four component age groups, barring 60+ years, Kerela recorded the lowest mean death rate values for rural Indian women.

In the age groups 0-4 years and 5-14 years, Madhya Pradesh reported the highest mean value $(17.70\pm2.94 \text{ and } 1.14\pm0.36)$, while Kerela $(2.79\pm0.47 \text{ and } 0.15\pm0.08)$ registered the lowest mean death rates for the rural Indian females. Chhattisgarh recorded the highest (3.76 ± 0.47) and Kerala the lowest mean death rates (1.56 ± 0.34) in 15-59 years of age. In the 60+ age group, Bihar documented the highest mean value (53.48 ± 5.55) , while Jammu & Kashmir (J&K) reported the lowest mean death rate (27.64 ± 5.1) . Furthermore, estimates of the coefficient of variation showed the highest variation in the 5-14 years age group and lowest variation in the 60+ years age group.

208

210 Age-specific Mortality Index scores of component age groups and its comparison between

211 the base year and reference year for rural Indian women

The study computed sub-indices for mortality with regard to each component age group and 212 compared their index scores for the base year (2011) and reference year (2018) (Table 2 & 3). 213 Compared to the base year, index scores of mortality of rural women for the age group of 0-4 years 214 215 increased for all the Indian states. Kerala accounted for the highest index score for 0-4 years in the base year (98.8) and in the reference year (99.8), and Madhya Pradesh documented the lowest 216 index scores (80.5 and 87.5) in both the years. In terms of the incremental change between the 217 218 base year and reference year for the age group 0-4 years, the highly improved (HI) states with the highest incremental changes include Madhya Pradesh (7.0) and Rajasthan (7.0). In contrast, the 219 least improved states with the lowest incremental changes were Maharashtra (0.5), Kerala (1.0), 220 221 and Tamil Nadu (1.6) (Fig. 1).

Fig. 1: Mapping of Indian states based on incremental changes in index scores for each component age group

In the age group 5-14 years, the index scores of states were relatively higher than other component age groups. However, there was a decline in the mortality index score for states that registered high index values in the base year. Fourteen states reported an increase in the mortality score in the reference year for this particular age group. A remarkable improvement was seen in Chhattisgarh (13.8) and Odisha (10.8) (**Fig. 1**). Meanwhile, Himachal Pradesh (-3.1), Jammu & Kashmir (-3.1), Karnataka (-1.6), and Maharashtra (-1.6) recorded negative changes in the mortality scores.

234 NI' = Not Improved (<=0); LI' = Least Improved (0-3); MI' = Moderately Improved (3.01-6); HI' = Highly Improved (235 (>6.01))

236 The ranks for each Indian state have been displayed in the parentheses of the table. * Denotes tied ranks.

237 ** J&K was an Indian state till 2019 and is now administered as a union territory by India.

For the 15-59 age group (**Table 3**), the mortality score of rural Indian women ranged from 68.0 to 238 95.1. Kerela reported the highest index scores in base (93.4) and reference years (95.1), while 239 Chhattisgarh reported the lowest scores in both years (76.2 & 68.0). There was no change in 240 Karnataka, Maharashtra, and Rajasthan index scores from base year to reference year. Based on 241 the incremental changes, Bihar showed the highest improvement (8.2), while Odisha (5.0) and 242 Madhya Pradesh (4.9) improved moderately in the age category 15-59 years (Fig. 1). The states 243 with negative changes in the mortality scores included Chhattisgarh (-8.2), Punjab (-4.9), Jammu 244 & Kashmir (-1.6), and Uttar Pradesh (-1.6) 245

A wide disparity of mortality scores for rural women was seen in the 60+ years age group ranging 246 from 37.4 to 92.2 in the reference year. Kerela (81.5) registered the highest index score in the base 247 year and Jammu & Kashmir (92.2) in the reference year. Jharkhand (50.2) and Bihar (37.4) 248 recorded the lowest index scores in the base year and reference year in this particular age group. 249 250 Ten states showed improvement in index scores from base year to reference year. Jammu & Kashmir recorded the highest improvement (13.9) in this age group. It was followed by Odisha 251 (9.6) and Gujarat (9.0) (Fig. 1). In contrast, Bihar (-27.5), Chhattisgarh (-16.0), and Tamil Nadu 252 (-6.1) documented notable negative changes in the mortality index values for this age group. At 253 all India level, the mortality scores sizably increased for both 0-4 (4.5) and 5-14 years age groups 254 (4.5), whereas it slightly improved and decreased for 15-59 (1.6) and 60+ (-0.8) age groups, 255 respectively for rural women. 256

Composite Age-specific Mortality Index (ASMI) scores of component age groups and its comparison between the base year and reference year for rural Indian women

269 A composite age-specific mortality index for rural Indian women was developed by aggregating

sub-indices for all component age groups using the geometric mean method (**Table 4**). The highest

mortality index score in the base year was 92.4, while the lowest was 74.6. In the reference year,

the index score range was 72.3 to 91.9. Kerala reported the highest composite index scores in the

base year (92.4) and reference (91.9). Jharkhand (74.6) and Bihar (72.3) documented the lowest

composite index scores in base and reference years, respectively. Fifteen states recorded anincrease in the index scores, out of which three states improved highly, four reported moderate

improvement, and eight made least improvements in the mortality scores (Fig. 2).

Fig. 2: Mapping of Indian states into typologies based on incremental changes of composite Age-Specific Mortality Index scores

283

Top and bottom performing Indian states based on Incremental changes in composite AgeSpecific Mortality Index scores for rural Indian women

Odisha reported the highest incremental change (7.8) from base year to reference year. Substantial 286 improvements were also observed in Madhya Pradesh (6.2) and Assam (6.1). On the contrary, 287 composite ASMI scores of Bihar (-6.3), Chhattisgarh (-3.6), Karnataka (-1.4), and Kerela (-0.5) 288 reported a decline. At all India level, the incremental change in the composite mortality index score 289 for rural women has witnessed a slight improvement (2.3). The incremental changes in the 290 composite index are depicted in Fig. 3. The top five performing states (Fig. 3) with regard to 291 composite mortality scores for rural Indian women have more or less remained the same, except 292 293 that West Bengal has replaced the state of Punjab in the reference year (S2 and S3 map). The bottom five performing states included Chhattisgarh, Assam, and Jharkhand in base and reference 294 years. Madhya Pradesh and Odisha in the base year were replaced by Uttar Pradesh and Bihar in 295 the reference year (Fig. 3) (S2 and S3 map). 296

Fig. 3: Positive and Negative Incremental changes in composite Age-Specific Mortality Index

scores along with top and bottom performing states for rural Indian women

299

300 Discussion

The study computed mortality index scores for four major component age groups and a composite 301 302 Age-specific mortality index for rural Indian women at the sub-national and national levels. Rural Indian women face several difficulties due to gender disparity and discrimination. Issues 303 concerning lack of educational opportunities, financial inclusion, proper medical care, hygiene, 304 305 and sanitation are widespread in rural areas and are encountered more by women than men [14,15]. Incremental changes in the index scores from the base to reference years have also been calculated. 306 Based on the incremental changes, the performance of states was categorized into four levels for 307 each component age group. 308

309 Out of the four age groups, the highest mean death rate was observed for the 60+ age group, while the lowest was for 5-14 years. The increase in mortality with age can be attributed to many factors. 310 Irrespective of gender, the possibility of getting a chronic disease and disability increases with age, 311 immunity, and strength also dwindle gradually, thus making the elderly more vulnerable to health 312 problems and increasing the risk of mortality [31–33]. Further, studies on treatment-seeking 313 behaviour in India revealed that the large majority of the elderly rural Indian population has unmet 314 healthcare needs, thereby further substantiating the high mean death rates for elderly females as 315 revealed by the present study [34]. Most deaths in the age group 5-14 years generally result from 316 317 communicable diseases. However, a rapid decline in mortality due to infectious diseases in this age group has contributed to lower death rates [35]. Further, a study revealed that females have 318 better survivorship in the under-five age group in India [36]. 319

Looking at the sub-national level, the state of Madhya Pradesh documented the highest mean death 320 rates among the states in the age groups 0-4 and 5-14 years, which can be attributed to women's 321 low literacy and the common practice of child marriage, especially in the rural areas of this state. 322 The state is among the backward states and trails behind the rest of India with regard to the 323 demographic transition [10]. Low literacy leads to a lack of awareness and affects the utilization 324 325 of Antenatal Care (ANC) services [37,38]. The prevalence of child marriage being interlinked with low literacy levels is significantly associated with abortions, premature deliveries, and low birth 326 weight infants resulting in high child mortality [38]. 327

Chhattisgarh topped mean death rates among rural females in the 15-59 years age group. It has been reported that 42% of deaths caused by malaria in India are from Chhattisgarh alone [39]. Rural populations, particularly females, were relatively at higher risk than their male counterparts as far as malaria mortality figures are concerned in this state [40]. The maternal mortality rates are also comparatively high in the state, thus adding to death rates in the 15-59 age group [39].

In the 60+ age group, Bihar documented the highest mean death rate value. Bihar is one of India's most populous and poorest states. It is usually placed at the lower end of all major Indian states as far as most socio-economic development parameters are concerned [11]. The prevalence and incidence of anemia were considerably high among females [41], particularly in the geriatric population [42]. With a lack of proper infrastructure and health services, the elderly population in rural areas succumb to these illnesses due to the inaccessibility of good healthcare services [43].

Jammu & Kashmir (J&K) reported the lowest mean death rate in the 60+ years. An increase in life expectancy in J&K has been noted from 1990 to 2016 [44]. In comparison to males, the life expectancy for females increased considerably by 10.86 years during the said period [44]. The determinants contributing to increased life expectancy include better healthcare delivery services,
improved health infrastructure, development of supply chain mechanisms, and quality medical
education in the state [45,46].

The study calculated the sub-indices for all component age groups. The index scores for 0-4 years 345 of all states increased from base year to reference year. It indicates that the mortality rates for the 346 age group 0-4 decreased from 2011 to 2018, which suggested better performance as far as death 347 rates in this early age group are concerned. This trend can be attributed to the reduction in the 348 under-5 mortality rate (U5MR), which has noticeably reduced from 66 deaths to 41 rural female 349 deaths per 1000 live births [47] from 2011 to 2018 in India. Further, the neonatal mortality rate 350 (NMR) has reportedly gone down by 38%, almost during a similar time period. The identifiable 351 reason behind this is the strengthened immunization programme incorporating an umbrella of 352 vaccines targeted to prevent fatal health outcomes[10,48,49]. 353

Kerala was the top mortality index scorer for all component age groups in both years except for 354 355 60+ years in the reference year. Similar outcomes were seen for mean death rates, where Kerela reported the lowest mean for all age groups barring 60+ years. According to the Health Index 356 report (2019-2020) of the National Institution for Transforming India (NITI) Aayog, which is the 357 Indian government's apex think tank, Kerela emerged as the top performer on multiple health-358 related indicators among the larger states [50]. The state's performance in recording lower rural 359 360 female death rates can be associated with various economic and health-related factors. Kerela has registered enormous improvement in income level in the last decade [51], and it presently falls 361 under the high per capita income and growth rate category [52]. The health infrastructure of Kerela 362 363 has shown extensive expansion between 2005-2019, and the state has witnessed a considerable increase in the number of Community Health Centres (CHCs) in rural areas. The number of 364

allopathic doctors at the Primary Healthcare Centres (PHCs) has also increased significantly [12].
To add to it, it is a front runner in female literacy rates [53] and maternal education in India [54].
In context to the present study results, Kerela registered high mortality index scores, but the
incremental change from base to reference year for each age group has been negligible [50]. The
reason could be the low mortality rates have already reached the saturation level, and only marginal
reduction is possible [55,56].

All Indian states recorded an improvement in the female mortality index scores for the 0-4 age 371 group. Therefore, despite having a noticeable appreciation in the index score from the base to the 372 reference year, Madhya Pradesh documented the lowest index score for both years. The health 373 374 index report by NITI Aavog also reported deterioration in performance by the state for NMR and U5MR [50]. The states of Himachal Pradesh, Jammu & Kashmir, Karnataka, and Maharashtra, 375 with high index scores in the base year, showed a decline in the reference year for the 5-14 age 376 group. A plausible explanation for this trend is that these states had recorded relatively high 377 mortality index scores in the reference year and had considerably reduced mortality to a great 378 extent for this age group. Subsequently, most public health interventions and programs were 379 directed toward reducing female mortality in other age groups [57]. 380

In the age group 15-59, Chhattisgarh reported the lowest index score for the base year, further decreasing in the reference year. A decline in three of four health outcomes has also been witnessed for Chhattisgarh in the NITI Aayog report [50]. Similarly, for the age group 60+ years, both Chhattisgarh and Bihar witnessed a worsening of their performance in the reference year, as revealed by their respective substantial decremental changes in female mortality index scores. These states are poverty-stricken states, with most poverty concentrated in their rural areas [51]. Huge gender disparities in education levels have been recorded [58,59], wherein both these states are plagued with low female literacy levels, resulting in mass poverty [58]. The states' health infrastructure is weak, with an acute shortage of doctors at PHCs [12]. Poverty makes the population more vulnerable to diseases, and the lack of healthcare services to address health problems results in high mortality rates.

The composite Age-specific Mortality Index (ASMI) exhibited results consistent with the sub-392 indices. In terms of overall index scores, the top five performers included Kerela, Himachal 393 Pradesh, Jammu & Kashmir, Maharashtra, and Punjab in the base year. Other studies pertaining 394 primarily to the overall health index have reported results on similar lines [23,50]. West Bengal 395 replaced Punjab in the reference year in the top five performers. The deterioration of performance 396 397 by Punjab in the age group 15-59 might have caused the change in overall rank. It could be a consequence of high maternal mortality in the region [60]. Punjab is also among the high HIV 398 incidence states leading to higher female deaths in the state [60]. Another study reported weakened 399 400 performance of Punjab in terms of a downward shift in various health outcomes [23].

401 The bottom five performing states were Chhattisgarh, Assam, Jharkhand, Madhya Pradesh, and Odisha in the base year. Chhattisgarh performed poorly for age groups 15-59 and 60+years and 402 thus showed a decline in overall score from base year to reference year. In contrast, Bihar and 403 Uttar Pradesh documented a decline in the performances in the reference year and entered the 404 405 bottom five performing states category, replacing the states of Odisha and Madhya Pradesh, which recorded highly improved incremental performance in terms of composite female rural mortality 406 407 scores. There was a drastic decline in the index scores of Bihar in 60+ years, causing an impact on the overall performance. The NITI Aayog health index also reported a decline in Bihar's 408 409 performance and a downward transition in all health outcomes, including institutional deliveries, Total Fertility Rates (TFR), Low Birthweight (LBW), success in treating tuberculosis, and 410

healthcare facilities and services [23]. Uttar Pradesh had also recorded decremental changes in
index scores for both 15-59 and 60+years, resulting in its entry into the bottom five performing
states in the reference year.

Kerela has remained at the top of its game, thereby emerging as the best-performing state in terms of overall rural female mortality scores in both the base and reference years. The probable reasons for this consistent performance have already been discussed earlier in this study. Additionally, the overall mortality composite score has shown minor improvement from base year to reference year at all India level. It indicates that there is still room for improvement as the composite score achieved by India (83.6.) in the reference year is still noticeable points away from the maximum potential (100) achievable.

421 The current study faces a few limitations. Due to the non-availability of data for all states, 19 out of 28 states were included in the study, leaving the scope for future studies to be conducted 422 incorporating the left-over states as and when the data is made available by the Indian government. 423 424 Since the data on age-specific mortality groups (0-4, 5-14, 15-59, 60+) from 1971 to 2001 was disaggregated into various small age groups (5-9, 10-14, 15-19, etc.), the average values of the 425 death rates were taken to concise them into four major component age groups to identify the 426 threshold values for data normalization. Therefore, these threshold values for specific component 427 age groups need to be used with caution in similar future research work. 428

Nevertheless, the present study has some strengths to offer. The 'composite Age-specific Mortality Index' is a pioneer endeavor to comprehensively quantify the mortality levels pertaining to rural Indian women at the sub-national level. The scope of usage of this unique 'composite index' is vast as it provides concise information from the complex and extensive data, which is more convenient

to communicate and report for policy plans. The index summarizes the overall performances of 433 the states and performances specific to component age groups, thus highlighting those age groups 434 which need attention from the policymakers and the government. This will facilitate the reduction 435 in mortality rates of rural Indian women at the national level as well. Further, the study has 436 categorized the Indian states into different typologies (not improved, least/moderately/highly 437 438 improved) based on their temporal performance from base to reference year. It will facilitate the laggard states to initiate customized policies/interventions to follow the performance trajectory of 439 the frontrunner states in terms of lower rural female mortality scores. Furthermore, the threshold 440 minimum and maximum values have also been identified for each component age group using the 441 historical mortality data at the Indian sub-national level, which shall serve as benchmark values to 442 be used and referred to in future academic and research endeavors. 443

444 Conclusions

An overall reduction in the mortality rates of rural Indian women has been observed over the years 445 in India. The success of public health interventions to reduce under five mortality rate is evident 446 as the female rural mortality rates have reduced sizably for all states. However, there is still 447 significant scope for improvement for all states in terms of reduction in mortality rates for other 448 component age groups. Further, there is a need to divert attention toward the female geriatric (60+ 449 years) population as the mortality rates are still high. Based on the incremental performance, the 450 gap between the top and bottom performing states in term of feinequalities mortality rates in the 451 rural areas is mainly attributed to multiple factors emerging from literature like, immunization 452 453 coverage, the proportion of registered Antenatal checkups (ANCs), institutional deliveries, total fertility rate, the number of healthcare providers, presence of dedicated health workforce and alike. 454 Robust policies and interventions should be developed at the state level to identify and address the 455

state-specific determinants, which will help in lowering the rural female mortality rates at thenational level.
