Abstract

<u>Background:</u> The effectiveness of a 3rd mRNA COVID-19 vaccine ("booster") dose against the omicron (B.1.1.529) variant is uncertain especially in older, high-risk populations.

<u>Objective:</u> To determine mRNA booster vaccine effectiveness (VE) against SARS-CoV-2 infection, hospitalization and death in the omicron era by type of booster, type of primary vaccine, time since primary vaccine, age and comorbidity burden.

Design: Target trial emulation study comparing booster vaccination versus no booster.

Setting: U.S. Department of Veterans Affairs (VA) healthcare system

<u>Participants and Intervention:</u> Among persons who had received two mRNA COVID-19 vaccine doses at least 5 months earlier, we designed this retrospective matched cohort study to emulate a target trial of booster mRNA vaccination (BNT162b2 or mRNA-1273) versus no booster, conducted from 12/01/2021 to 03/31/2022.

Measurements: Booster VE.

Results: Each group included 490,838 well-matched persons, predominantly male (88%), mean age 63.0±14.0 years, followed for up to 121 days (mean 79.8 days). Booster VE >10 days after booster was 42.3% (95% CI 40.6-43.9) against SARS-CoV-2 infection, 53.3% (48.1-58.0) against SARS-CoV-2-related hospitalization and 79.1% (71.2-84.9) against SARS-CoV-2-related death. Booster VE was similar for different booster types (BNT162b2 or mRNA-1273), age groups or primary vaccination regimens, but was significantly higher with longer time since primary vaccination and with higher comorbidity burden.

Limitations: Predominantly male population.

<u>Conclusions</u>: Booster mRNA vaccination was highly effective in preventing death and moderately effective in preventing infection and hospitalization for up to 4 months after administration in the omicron era. Increased uptake of booster vaccination, which is currently suboptimal, should be pursued to limit the morbidity and mortality of SARS-CoV-2 infection, especially in persons with high comorbidity burden.

Primary Funding Source: Department of Veterans Affairs

Introduction

The Centers for Disease Control and Prevention (CDC) recommends that all persons 5 years and older receive a 3rd dose ("booster") of an mRNA COVID-19 vaccine (Pfizer-BioNTech's BNT162b2 or Moderna's mRNA-1273) at least 5 months after receipt of the second mRNA vaccine dose¹. Despite these recommendations, uptake of booster vaccination in the United States remains low at ~35.8% as of 6/12/2022².

A booster BNT162b2 dose increases neutralizing antibody levels³. A phase 3 randomized controlled trial conducted in the delta (B.1.617.2) variant era reported fewer SARS-CoV-2 infections in persons randomized to a booster dose of BNT162b2 (6 out of 5081) than in persons randomized to placebo (123 out of 5044)⁴. Real-world studies conducted in the delta variant era estimated that booster vaccine effectiveness (VE) against infection, hospitalization and death was very high ranging from 86 to 95.3%⁵⁻¹⁰.

In December 2021, the omicron (B.1.1.529) variant became dominant worldwide, including in the United States¹¹. The omicron variant is thought to be more likely to evade immunity or cause breakthrough infection after vaccination than the delta variant¹². Indeed, emerging evidence suggests that booster VE against infection and hospitalization caused by the omicron variant is much lower^{9,13-15}. Booster VE against the omicron variant requires further investigation especially in older, racially/ethnically diverse populations with high prevalence of comorbid conditions, who have the highest risk of morbidity and mortality from COVID-19. Furthermore, studies are needed to determine whether booster VE varies by type of booster, type of primary vaccine, time since primary vaccine, age group and comorbidity burden in the omicron era.

The Veterans Affairs (VA) healthcare system, the largest national, integrated healthcare system in the United States, includes a large proportion of older adults with multimorbidity and has provided an adequate framework for multiple target trial emulation studies of the comparative effectiveness of COVID-19 vaccination¹⁶⁻¹⁸. We used target trial emulation principles¹⁹ to specify and emulate a trial comparing booster mRNA COVID-19 vaccination versus no booster during the omicron era with respect to risk of infection, hospitalization and death.

Methods

Specification and emulation of target trials: Overall study design

We designed this retrospective matched cohort study to emulate a target randomized controlled trial of booster (i.e. 3rd dose) mRNA COVID-19 vaccination (BNT162b2 or mRNA-1273) versus no booster among persons who had already received two mRNA COVID-19 vaccinations at least 5 months earlier in the national VA healthcare system in a period of omicron variant predominance. The enrollment and follow-up period was between 12/1/2021 and 03/31/2022. During this period all persons who had completed more than 5 months since their primary COVID-19 immunization were eligible for booster vaccination in the VA irrespective of age or risk factors. We used a matched cohort design to emulate the balance achieved through randomization, with eligible persons matched on the date of their booster dose to their comparator(s) who had not received a booster dose as of that date. Each matched set was followed from the date of booster vaccination ("time zero"). This design ensured that the same time zero served as the date at which eligibility was determined and treatment was initiated and anchored the follow-up for both study arms (Supplementary Figure 1), thus minimizing immortal time and selection biases²⁰. For each participant follow-up continued until the earliest of the following events: occurrence of an outcome event, death unrelated to COVID-19, booster vaccination of the comparator (with matched set censoring), or the end of the follow-up period (March 31, 2022). Supplementary Table 1 compares the critical study design features of the specified and emulated target trials.

We used data from the VA's Corporate Data Warehouse (CDW), a relational database of VA enrollees' comprehensive electronic health records (EHR) and the VA COVID-19 Shared Data Resource (CSDR), which includes analytic variables provisioned by the VA Informatics and Computing Infrastructure (VINCI)²¹. We supplemented with additional claims data from the VA Community Care program (non-VA care paid by a VA facility) and from the Centers for Medicare and Medicaid Services (CMS) obtained through the VA Information Resource Center (VIReC)²².

Eligibility criteria and study population.

We identified all VA enrollees aged 18 years or older who were alive as of 12/01/2021 and had received exactly two doses of mRNA vaccination documented in the VA system with the second dose administered at least 5 months earlier (n=2,097,357) – see **Figure 1**. We excluded persons who: had evidence of SARS-CoV-2 infection prior to 12/01/2021, using a combination of VA and CMS data; had incongruent first and second doses of primary vaccination; had missing residential address zip code; did not have an inpatient or outpatient or primary care encounter in the VA healthcare system in the preceding 24 months; or were not assigned to a unique VA Integrated Service Network (VISN), the 19 administrative regions of VA²³. Among the remaining 1,687,421 persons, 505,585 received a booster mRNA vaccine dose between 12/01/2021 and 03/31/2022 documented in the VA healthcare system and could potentially be included in the booster arm of the emulated trial if they could be matched to appropriate unboosted comparators. We captured booster doses administered by VA pharmacy, through VA-funded community care, outside the VA and documented in VA records or documented in CMS data.

Cohort matching

We matched eligible persons who did or did not receive a booster anchored around the same calendar date of booster vaccination^{17,24}. In each 1-week period of the study, we identified among the eligible study participants those who were alive, uninfected and had not yet received booster vaccination as of the first day of the week. Among them, we identified all potential participants in the treatment arm, defined as those who received a booster mRNA vaccine during the given week and all potential comparators, who had not received a booster vaccine at the start of the week. We used the baseline characteristics of all persons to identify the best-matched comparator(s) for each person who received a booster dose using exact matching based on VISN, age (6-year buckets), Charlson Comorbidity Index²⁵ (CCI) (3-point buckets), primary COVID-19 vaccination type (BNT162b2 or mRNA-1273) and date of completion of primary vaccination (6-week buckets). The exact matching factors were selected because they were known to be strongly associated with the probability of receiving a booster (the exposure) as well as with the risk of development of SARS-CoV-2 infection, hospitalization or death (the outcomes) in VA patients²⁶⁻³⁰.

To further reduce confounding as numerous covariates not used in the match remained imbalanced after exact matching, we then executed propensity score matching (calipers within 0.2 standard deviations from the mean) with replacement to identify the best match for each booster dose recipient in a 1:K variable ratio, where K varied based on the number of propensity score ties. We used the following covariates in the propensity score logistic regression model selected a priori based on being associated with both the exposure and the outcome: age, sex, self-reported race and ethnicity, urban/rural residence (based on zip codes, using data from the VA Office of Rural Health³¹, which uses the Secondary Rural-Urban Commuting Area [RUCA] for defining rurality), CCI, body mass index (BMI, calculated using measured weight and height), diabetes, congestive heart failure (CHF), chronic obstructive pulmonary disease (COPD), chronic kidney disease (CKD), receipt of immunosuppressant medications in the 2 years prior (see Supplementary Table 2) and the Care Assessment Need (CAN) score. The CAN score is a validated measure of 1-year mortality in VA enrollees calculated using socio-demographics, clinical diagnoses, vital signs, medications, laboratory values, and health care utilization data from VA's national EHR^{26,32}. Diabetes, CHF, COPD and CKD were defined by international classification of disease, tenth revision (ICD-10) codes documented in VA EHR in the 2-year period prior to the study(see Supplementary Table 3 for these ICD10 codes)³³. The two-step matching process was repeated 16 times for each 1-week period between 12/01/21 and 03/31/22, with a separate propensity score model developed for each week to account for dynamic changes in booster uptake and infection incidence that were occurring during the study period. Persons who received booster vaccination were eligible for inclusion in the treatment arm, even if they had previously been selected as a matched comparator. Persons who did not receive a booster dose could serve as matched comparators to more than one person in the treatment arm. The matching strategy was implemented using STATA's kmatch command³⁴ (StataCorp, College Station, TX. USA).

Primary endpoints

The trial had three primary endpoints: SARS-CoV-2 infection, SARS-CoV-2-related hospitalization and SARS CoV-2-related death.

SARS-CoV-2 infection was defined as a positive test for SARS-CoV-2 nucleic acid amplification test or antigen in a respiratory specimen within the VA system as well as such tests performed outside the VA but documented in VA records. Such positive tests are identified by the VA National Surveillance Tool and have been used by our group and others to support target trial emulation studies¹⁶⁻¹⁸. The earliest date of a documented positive test was taken as each participant's date of infection.

SARS-CoV-2-related hospitalization was defined as hospitalization documented in the VA healthcare system or in CMS on or within 30 days after a positive test and SARS-CoV-2-related death as death from any cause within 30 days of a positive test; these definitions have been used in multiple prior VA studies^{16-18,26,27,29,30}. Deaths occurring both within and outside the VA are comprehensively captured in the VA Corporate Data Warehouse (CDW) from a variety of VA and non-VA sources including VA inpatient files, VA Beneficiary Identification and Records Locator System (BIRLS), Social Security Administration (SSA) death files, and the Department of Defense ³⁵. To ensure that deaths and hospitalizations that occurred on or before 03/31/22 were adequately captured we last accessed relevant data sources on 05/21/22.

Statistical analysis: estimates of booster vaccine effectiveness

Baseline characteristics between the booster and no booster groups were compared using standardized differences. Unadjusted differences in incident outcome rates were estimated via Kaplan-Meier estimator for a period of 121 days, the study's maximum follow-up.

We used Cox proportional hazards regression to compare booster vaccine recipients and their matched comparators with respect to the risk of developing the three study outcomes, with follow-up extending to 03/31/2022. Follow-up began from time zero in both groups and was limited to matched sets in which all individuals were still at risk 10 days after time zero since there is no expectation of protective effect within the first 10 days after vaccination. We calculated the incidence of each outcome and the hazard ratio adjusted for type of primary COVID-19 mRNA vaccine, time since 2nd COVID-19 mRNA vaccine, sex, age, race, ethnicity, urban/rural residence, BMI, CCI, diabetes, CKD, CHF, COPD, CAN score, and immunosuppressant medications and stratified by VA VISN, to account for any residual confounding that

might have been present after matching. Booster vaccine effectiveness (VE) was estimated as (1-adjusted hazard ratio) and served as the study's primary outcome. Booster VE was estimated for the entire population and also for subgroups determined *a priori* based on type of booster (BNT162b2 or mRNA-1273), type of primary vaccination (BNT162b2 or mRNA-1273), time since primary vaccination (5-9 or >9 months), age groups, CCI categories. A χ^2 -test of no difference between the predicted adjusted hazard ratios in models with and without an interaction term was used to evaluate differences in VE between subgroups.

Missing values in sex, BMI, CAN score, race and ethnicity were uncommon and were imputed using deterministic imputation.

We compared as a negative outcome control³⁶ the incidence of SARS-CoV-2 infection within ten days after time zero in the two groups, which should not be affected by vaccination, to verify there was no uncontrolled residual confounding after matching or any ascertainment bias.

All analyses were weighted to account for variable-ratio matching and matching with replacement. A robust sandwichtype variance estimator was used to account for clustering within matched group (because of ties in the propensity score), clustering within subjects (because of matching with replacement), and clustering in the cross-classification of the matched and within subject clusters³⁷. We verified that the proportional hazards assumption was met using log-log plots and Schoenfeld residuals.

Role of the funding source

The funding source did not have any involvement in study design, data collection, data analysis, data interpretation or in writing of the article.

Results

Baseline characteristics of emulated trial participants

Baseline characteristics were well balanced between the booster arm (n=490,838) and their matched comparators (n=490,838 representing 404,196 unique persons) (**Table 1**). Matching with replacement allowed the matching of >97% of persons who received a booster dose. Baseline characteristics of all eligible boosted and unboosted individuals before matching are shown in **Supplementary Table 4** and **Supplementary Figure 2**.

Both matched groups were predominantly male (87.4% vs. 87.7%), had advanced mean age (63.0 ±14 yrs in both groups), diverse racial/ethnic distribution (e.g. Black 21.8% vs. 22.2%, Hispanic 8.6% vs. 8.2%) and a substantial comorbidity burden (mean CCI 1.3±1.7 in both groups). Major comorbid conditions such as diabetes, CHF, COPD and CKD and exposure to immunosuppressant medications were common and nearly equally distributed in the two groups. The mean number of days (273±36) since completion of primary vaccination was almost identical in the two groups with ~48% in each group having received the second dose of the vaccine >9 months prior to time zero.

Booster vaccine effectiveness against infection

486,616 out of 490,838 (99.1%) matched sets remained under follow-up and at risk at day 10 after time zero and were included in VE estimations (**Tables 2-4**). During a mean follow-up of 79.8 days identical in the two groups, (maximum 121 days), 17,384 SARS-CoV-2 infections were documented >10 days after time zero, including 6,438 in the booster cohort and 10,946 in the matched no booster cohort (**Table 2**). 85% (14,823/17,384) of these infections occurred after 01/01/22, when omicron accounted for almost 100% of infections¹¹ in the USA and an additional 14% (2467/17,384) from 12/16-12/31/22 when omicron accounted for the majority of infections, while only 0.5% (94/17,384) occurred before 12/16/22.

Cumulative incidence of infection at 121 days was significantly lower in the booster (16.0 per 1000 persons) than in the no booster (27.0 per 1000) cohort (risk difference -11 per 1000, 95% CI -11.6 to -10.3) (**Figure 2 and Table 2**). Booster VE against infection was 42.3% (95% CI 40.6-43.9) overall, 39.0% (36.4-41.6) for BNT162b2 and 44.6% (42.5-46.6) for mRNA-1273 booster (interaction p-value 0.12) — see **Supplementary Figure 3** for cumulative incidence curves by booster type. Booster VE was higher in those with >9 months since primary vaccination (46.5% [44.1-48.5]) than in persons with 5-9 months since primary vaccination (36.4% [33.3-39.4]) (interaction p-value<0.01). Booster VE appeared to be higher in persons with more comorbidities (interaction p-value<0.01) but lower in older age groups(interaction p-value<0.01) (**Table 2**).

Booster vaccine effectiveness against SARS-CoV-2-related hospitalization

A total of 1575 SARS-CoV-2-related hospitalizations were documented during follow-up, including 515 in the booster cohort and 1060 in the matched no booster cohort (**Table 3**). Cumulative incidence of SARS-CoV-2-related hospitalization at 121 days was significantly lower in the booster (1.3 per 1000 persons) than in the no booster (2.7 per 1000) group (risk difference -1.4 per 1000, 95% CI -1.6 to -1.2) (**Figure 2 and Table 3**).

Booster VE against hospitalization was 53.3% (48.1-58.0) overall, 54.0% (46.1-60.8) for BNT162b2 and 52.9% (45.6-59.2) for mRNA-1273 booster (p-value for interaction by booster type 0.59) – see **Supplementary Figure 3** for cumulative incidence curves by booster type. Booster VE was higher among persons with >9 months since primary vaccination (interaction p-value<0.01) and in persons with more comorbidities (interaction p-value<0.01) with no appreciable differences across age groups or primary vaccination types.

Booster vaccine effectiveness against SARS-CoV-2-related death

A total of 262 SARS-CoV-2-related deaths were documented during follow-up, including 47 in the booster cohort and 215 in the matched no booster cohort (**Table 4**). Cumulative incidence of SARS-CoV-2-related death at 121 days was significantly lower in the booster (0.1 per 1000 persons) than in the no booster (0.6 per 1000) group (risk difference -0.5 per 1000, 95% CI -0.6 to -0.4) (**Figure 2 and Table 4**). Booster VE against death was 79.1% (71.2-84.9) overall, 85.5% (73.9-92.0) for BNT162b2 and 75.2% (62.9-83.4) for mRNA-1273 booster (p-value for interaction by booster type 0.48) –

see **Supplementary Figure 3** for cumulative incidence curves by booster type. Booster VE was not significantly different across age and CCI groups and according to time since primary vaccination or primary vaccination type.

Negative outcome control

Cumulative incidence of SARS-CoV-2 infection during the first 10 days after time zero was nearly identical in the booster and matched no booster cohorts (**Figure 1d** and **Table 2**), suggesting adequate matching and lack of substantial unmeasured confounding.

Discussion

Our target trial emulation study performed in the national VA healthcare system demonstrated that mRNA booster vaccination administered at least 5 months after primary vaccination had an estimated VE of 42.3% (40.6-43.9) against infection, 53.3% (48.1-58.0) against hospitalization and 79.1% (71.2-84.9) against death during follow-up extending up to 121 days in an omicron variant predominant era. Booster VE was similar for different booster types (BNT162b2 or mRNA-1273), age groups and primary vaccination regimens, and increased with longer time since primary vaccination and with greater comorbidity burden. These findings provide strong support for current CDC recommendations that all persons should receive a booster vaccination >5 months after completion of primary immunization.

Booster VE against SARS-CoV-2 infection with the delta variant was found to be very high in a phase 3 randomized controlled trial⁴ and observational cohort studies from Israel^{5,6}, ranging from 86% to 95.3%. However, a population-based matched cohort study from Qatar reported that mRNA booster VE in the omicron era was much lower at 49.4% (47.1-51.6) against symptomatic infection and 76.5% (55.9-87.5) against hospitalization or death¹³, with follow-up extending up to 35 days. Unlike the population we studied, only 9% of the population of Qatar are over age 50, few were reported to have serious coexisting conditions and no individual-level comorbid conditions were available for matching, adjustment or subgroup analysis. A target trial emulation using matched cohorts derived from nationwide population registries in Spain estimated that mRNA booster VE against infection in the omicron era was 51.3% (50.2-52.4) with follow-up extending only up to 34 days¹⁴ – comorbid conditions were unavailable for matching, adjustment or sub-group analyses. A test-negative, case-control study from England reported that booster VE against infection was 67.2% (66.5-67.8) at 2-4 weeks after receipt of a BNT162b2 booster before declining to 45.7% (44.7-46.7) at 10 or more weeks¹⁵. We found even lower booster VE in the omicron era against infection (42.3% [40.6-43.9]) and hospitalization (53.3% [48.1-58.0]), which may be related to the greater comorbidity burden of our study population and the longer follow-up extending up to 121 days. Taken together these studies suggest that booster VE against infection and hospitalization is lower in the omicron era than it was in the delta era and likely declines over time.

Our study demonstrated a much higher booster VE against SARS-CoV-2-related death (79.1% [71.2-84.9]), which was not assessed in prior studies in the omicron era. An Israeli population-based study conducted in the delta era reported that BNT162b2 booster recipients had 90% lower mortality due to Covid-19 than participants who did not receive a booster, which is higher than what we found in the omicron era.

Some studies reported that mRNA-1273 booster VE against infection was slightly higher than BNT162b2 booster VE¹⁴ but others did not¹³. We found that booster VE against infection, hospitalization and death was not significantly different between mRNA-1273 and BNT162b2. Future target trials specifically designed to compare mRNA-1273 versus BNT162b2 boosters are needed to address this question directly.

As in prior studies^{13,14}, we found that booster VE against infection and hospitalization was significantly higher as more time accrued since primary vaccination (>9 vs. 5-9 months). This is most likely related to the waning protection of primary vaccination over time in the comparator, no-booster group. Booster VE was also substantially higher in groups with greater comorbidity burden. Since these groups also have the highest absolute risk of adverse COVID-19 outcomes, this resulted in much greater risk differences in infection, hospitalization and death between the booster and no booster groups in persons with high comorbidity burden. These results reinforce the need to ensure booster vaccination especially in persons with high comorbidity burden.

Receipt of booster dose vaccination has been documented in only 35.8% of the United States population as of 06/12/2022, a far lower proportion than countries such as Uruguay (76.1.3%), Iceland (67.9%), Italy (67.5%), Germany (58.7%), the United Kingdom (58.3%) and Israel (57.2%)². Our data suggest that achieving higher rates of booster vaccination represents an important opportunity to reduce SARS-CoV-2 related morbidity and mortality. At the same time the lower booster VE against omicron than was previously observed against delta variants suggests that

development of new generation of broadly effective vaccines, including potentially "universal coronavirus vaccines", may be a better strategy than repeated booster vaccination with existing vaccines³⁸.

Our study has the following limitations. Despite adherence to principles of target trial emulation, a matching method that resulted in balanced distribution of baseline characteristics in the two arms and adjustment for potential confounders, residual confounding cannot be completely excluded in a non-randomized study. However, our analysis of a negative outcome control (infection rate in the first 10 days after time zero) suggested little confounding. While some additional infections (diagnosed or undiagnosed) and hospitalizations undoubtedly occurred and were not captured in our analysis, we would expect this outcome misclassification to be nondifferential. Non-differential misclassification would have minimal impact on relative measures of effect (i.e. VE), although absolute risks and risk differences may have been slightly underestimated. If any booster doses were missed (i.e. not administered within VA or VA community care or documented in VA records or Medicare data) among matched comparators, such misclassification would tend to attenuate the reported VE. Our study population is predominantly male, which may limit the generalizability of our findings to women.

In conclusion, in a target trial emulation study of older Veterans with high burden of comorbidity conducted in the omicron era, mRNA booster VE against SARS-CoV-2 infection (42.3%) and SARS-CoV-2-related hospitalization (53.3%) were slightly lower than previously reported but VE against SARS-CoV-2-related death was high (79.1%). Improved booster vaccination should be pursued to reduce COVID-19 morbidity and mortality especially in persons with multiple comorbid conditions.

<u>Figure 1.</u> Eligibility criteria and matching process resulting in the selection of study populations for the emulation of a target trial comparing the effectiveness of booster mRNA COVID-19 vaccination versus no booster in the national Veterans Affairs healthcare system from December 1, 2021 to March 31, 2022

^{*} Dotted arrow refers to persons who received a booster dose who could serve as comparators in prior time periods before receiving their booster dose

Figure 2. Kaplan-Meier curves comparing persons who received a booster mRNA COVID-19 vaccine versus their matched counterparts who did not with respect to the cumulative incidence (%) and 95% confidence intervals of SARS-CoV-2 infection (a), SARS-CoV-2-related hospitalization (b), SARS-CoV-2-related death (c) and SARS-CoV-2 infection during the first 10 days after time zero (d) (negative outcome control).

c. SARS-CoV-2-related death

Table 1. Baseline sociodemographic and clinical characteristics of persons who received a booster dose of mRNA COVID-19 vaccination in the VA healthcare system and their matched counterparts who did not receive a booster dose from December 1, 2021 to March 31, 2022.

Contents

Supplementary Table 1. Specification and emulation of a target trial evaluating the effectiveness of booster (i.e. third dose) mRNA COVID-19 vaccination conducted from December 1, 2021 to March 31, 202230 Supplementary Table 3: ICD10 Codes used to define diabetes, congestive heart failure (CHF), chronic obstructive Supplementary Table 4. Baseline sociodemographic and clinical characteristics of persons who received a booster dose of mRNA COVID-19 vaccination in the VA healthcare system and their unmatched counterparts who did not receive a Supplementary Table 5. Baseline sociodemographic and clinical characteristics of persons who received a booster dose of mRNA COVID-19 vaccination in the VA healthcare system and their matched counterparts who did not receive a booster dose from December 1, 2021 to March 31, 2022, and for whom all members of matched sets were still at risk 10 Supplementary Figure 1. Schematic representation of the method used to match person(s) who did not receive a booster mRNA vaccine to each person who received a booster mRNA vaccine, within each 1-week period during the Supplementary Figure 2. Comparison of baseline characteristics of persons who received a booster dose mRNA COVID-19 vaccine and their comparators who did not, before and after matching, demonstrate excellent balance after matching Supplementary Figure 3. Kaplan-Meier curves comparing persons who received a booster mRNA COVID-19 vaccine versus their matched counterparts who did not with respect to the cumulative incidence (%) and 95% confidence intervals of SARS-CoV-2 infection (a) (b), SARS-CoV-2-related hospitalization (c)(d) and SARS-CoV-2-related death (e)(f).

<u>Supplementary Table 1.</u> Specification and emulation of a target trial evaluating the effectiveness of booster (i.e. third dose) mRNA COVID-19 vaccination conducted from December 1, 2021 to March 31, 2022

TARGET TRIAL SPECIFICATION	TARGET TRIAL EMULATION
ELIGIBILITY CRITERIA	
VA enrollees age ≥18 years	Same
Received two doses of mRNA COVID-19	Same
vaccination at least 5 months before enrollment	
No prior known infection with SARS-CoV-2	
documented in VA (or Medicare) records	
Known residential address	Same
User of VA healthcare system, defined as having	Same
any outpatient or inpatient encounter in the VA	
healthcare system in the preceding 24 months	
Having a documented primary care physician	Same
(PCP) visit in the preceding 24 months	
TREATMENT STRATEGIES	
Received booster dose mRNA vaccination	Same.
between December 1, 2021 and April 4, 2022 versus no booster dose	
TREATMENT ASSIGNMENT	
Randomization:	Sequential matching:
Eligible persons are randomly assigned to booster	A two-step matching process was used to emulate
mRNA COVID-19 vaccination versus no booster	the balance in baseline characteristics achieved by
THREAT COVID 15 VACCINATION VETSUS NO BOOSTEE	randomization. Eligible persons were matched on
	the date of their booster dose to their
	comparator(s) who did not receive a booster dose
	as of that date by:
	a. Exact-matching on the following characteristics
	VA region or "VISN" (19 regions throughout
	USA)
	Age (6-year buckets)
	Charlson comorbidity index (3-point buckets)
	 Primary COVID-19 vaccination type (BNT162b2 or mRNA-1273)
	Time since completion of primary vaccination
	(6-week buckets)
	b. Propensity score matching
	After exact-matching, we executed propensity
	score matching to identify the best match for each
	booster dose recipient. We used matching with
	replacement in a 1:k variable ratio, where k varied
	based on the number of propensity score ties. We included all ties to avoid imbalance due to random
	pruning.
	Characteristics included in the propensity score
	logistic regression model were:
	Age
	U

	Sex Race Ethnicity Urban/rural residence Charlson Comorbidity Index (CCI) Body mass index
	Diabetes
	Congestive heart failure (CHF) Chronic obstructive pulmonary disease (COPD)
	Chronic kidney disease (CKD)
	Receipt of immunosuppressant medications in the
	2 years prior Care Assessment Need (CAN) score
OUTCOMES	care Assessment Need (CAN) score
Laboratory-confirmed SARS CoV-2 Infection, documented by a nucleic acid amplification test (NAAT) or antigen test. SARS-CoV-2-related hospitalization: any hospitalization on or within 30 days following SARS-CoV-2 infection documented in VA or CMC records	Same as for target trial
SARS-CoV-2-related death: death due to any	
cause on or within 30 days following SARS-CoV-2 infection	
FOLLOW-UP	
Follow-up starts on the date of booster dose vaccination or the equivalent index date for the matched comparator who did not receive a booster.	Same as for target trial
CAUSAL CONTRASTS	
Intention-to-treat effect	Observational analogue of the per-protocol effect
Per-protocol effect, i.e. the effect if all individuals	
had received their assigned treatment STATISTICAL ANALYSIS	
Hazard ratios and risk differences for each of the outcomes. Vaccine effectiveness was estimated as (1- hazard ratio)	Same as for target trial

<u>Supplementary Table 2</u>. Immunosuppressive and cancer medications.

We identified prescription of these medications within the 2-year period prior to the study period as evidence of being on potentially immune suppressive medications

Drug class	Drugs
Alkylating agents	bendamustine, busulfan, chlorambucil, cisplatin,
	cyclophosphamide, ifosfamide, lurbinectedin,
	melphalan, nitrogen mustard procarbazine,
	temozolomide
Anti-CD19/CD3	blinatumomab
Anti-HER2	trastuzumab
Antimetabolites	azathioprine, capecitabine, cladribine, cytarabine,
	fludarabine, floxuridine, fluorouracil, gemcitabine,
	mercaptopurine, methotrexate, pemtrexed, pentostatin,
	pralatrexate, thioguanine
Antitumor antibiotics	bleomycin, dacarbazine, dactinomycin, daunorubicin,
	doxorubicin, epirubidin, idarubicin, mitomycin,
	mitoxantrone
B-cell depletion and inhibition	belimumab, ibriumomab, tiuxetan, obinutuzumab,
	ocrelizumab, ^b ofatumumab, ^b rituximab ^b
BCL2 inhibitors	venetoxlax
Interferon	interferon alpha-2a, interferon alpha-2b, interferon
	beta-1a, interferon beta-1b, interferon gamma,
	interferon gamma-1b
BCR-ABL tyrosine kinase inhibitors	bosutinib, dasatinib, imatinib, nilotinib, ponatinib
Bruton tyrosine kinase (BTK) inhibitors	acalabrutinib, ibrutinib, zanubrutinib
Calcineurin inhibitors	cyclosporine, pimecrolimus, tacrolimus, voclosporin
Complement inhibitor	eculizumab
EGFR inhibitors	afatinib, cetuximab, dacomitinib, erlotinib, gefitinib,
	lapatinib, mobocertinib, necitumumab, osimertinib,
	panitumumab
Glucocorticoids (systemic)	cortisone acetate, betamethasone, budesonide,
	dexamethasone, hydrocortisone, methylprednisolone,
	prednisolone, prednisone
Histone deacetylase inhibitors	belinostat, vorinostat

IL-1 inhibitors	anakinra, canakinumab, rilonacept
IL-12/23 inhibitors	guselkumab, ustekinumab
IL-17 inhibitors	brodalumab, ixekizumab, secukinumab
IL-4/13 inhibitors	dupilumab
IL-5 inhibitors	benralizumab, mepolizumab, reslizumab
IL-6 inhibitors	sarilumab, siltuximab, tocilizumab
Immune checkpoint inhibitors (anti-CTLA-	ipilimumab
4)	
Immune checkpoint inhibitors (anti-PD-1)	cemiplimab, dostarlimab, nivolumab, pembrolizumab
Immune checkpoint inhibitors (anti-PD-L1)	atezolizumab, avelumab, durvalumab
Immune globulin	anti-thymocyte globulin ^b
Immunosuppressant agent	mycophenolate mofetil (MMF), mycophenolate sodium
Janus kinase (JAK) inhibitors	baricitinib, ruxolitinib, tofacitinib, upadacitinib
Miscellaneous antineoplastics	arsenic trioxide, blinhydroxyurea, idelalisib, olaparib,
	omacetaxine, palbociclib, pegaspargase, thalidomide,
	trabectedin
Miscellaneous biological	glatiramer acetate
Miscellaneous other	leflunomide, sulfasalazine
mTOR kinase inhibitors	everolimus, sirolimus, temsirolimus
Nitrosoureas	carmustine, lomustine, streptozocin
Platinum derivatives	carboplatin, oxaliplatin
Proteasome inhibitors	bortezomib, carfilzomib
Selective adhesion-molecule inhibitors	natalizumab, vedolizumab
T-cell costimulation inhibitors	abatacept, belatacept, alemtuzumab,² basiliximab
Thalidomide analogs	lenalidomide, pomalidomide
TNF inhibitors	adalimumab, certolizumab, etanercept, golimumab,
	infliximab
Topoisomerase inhibitors	irinotecan, mitoxantrone, topotecan
Tubulin-acting agents	eribulin, etoposide, ixabepilone
Tubulin-acting agents (taxanes)	cabazitaxel, docetaxel, nabpaclitaxel, paclitaxel
Tubulin-acting agents (vinca alkaloids)	vinblastine, vincristine, vinorelbine

VEGF tyrosine kinase inhibitors	aflibercept, axitinib, bevacizumab, lenvatinib, pazopanib,
	ramucirumab, regorafenib, sorafenib, sunitinib,
	vandetanib

<u>Supplementary Table 3:</u> ICD10 Codes used to define diabetes, congestive heart failure (CHF), chronic obstructive pulmonary disease (COPD) and chronic kidney disease (CKD).

The presence of these conditions was defined by documentation of one or more of these ICD10 codes recorded in VA electronic health records (both outpatient or inpatient records) during the 2-year period prior to the date of vaccination. We used lists of ICD10 codes developed by the VA's Centralized Interactive Phenomics Resource or CIPHER to define each condition. CIPHER develops and validates EHR-based phenotype algorithms and definitions. CIPHER is available through VA intranet at:

https://vhacdwdwhweb100.vha.med.va.gov/phenotype/index.php/VA_Phenomics_Library - Centralized Interactive Phenomics Resource (CIPHER)

Phenotype	Code	CodeDescription
CONGESTIVE	HEART FAIL	URE (CHF)
CHF	150.20	Unspecified systolic (congestive) heart failure
CHF	150.21	Acute systolic (congestive) heart failure
CHF	150.22	Chronic systolic (congestive) heart failure
CHF	150.23	Acute on chronic systolic (congestive) heart failure
CHF	150.30	Unspecified diastolic (congestive) heart failure
CHF	150.31	Acute diastolic (congestive) heart failure
CHF	150.32	Chronic diastolic (congestive) heart failure
CHF	150.33	Acute on chronic diastolic (congestive) heart failure
CHF	150.40	Unspecified combined systolic (congestive) and diastolic (congestive) heart failure
CHF	150.41	Acute combined systolic (congestive) and diastolic (congestive) heart failure

Supplementary Figure 1. Schematic representation of the method used to match person(s) who did not receive a booster mRNA vaccine to each person who received a booster mRNA vaccine, within each 1-week period during the target trial period.

Supplementary Figure 1 Caption.

The schematic shows a specific person during the 1-week period from 01/3/2022 to 01/9/2022 who received a booster mRNA vaccine dose on 01/8/1022 and met all of the target trial's eligibility criteria and did not have SARS-CoV-2 infection as of 01/8/2022. This person is matched to a person who did not receive a booster vaccine dose as of 01/8/2022 (i.e. had only received two mRNA doses), who also fulfilled all the eligibility criteria and was alive as of 01/8/2022, and had the same VISN, type of primary vaccination, week of primary vaccination completion (within 6 weeks), age (within 6 years) and Charlson Comorbidity Index (CCI, within 3 points) as the booster dose recipient, and has a propensity score within 0.2 standard deviation of the mean (sdm) of that of the booster dose recipient. In practice, the propensity score difference between matched sets ranged from 0.0002-0.0033 sdm. Both persons in the matched pair have to remain at risk (i.e. alive, uninfected) as of the date 10 days later, after which outcomes are ascertained for the calculation of vaccine effectiveness

<u>Supplementary Figure 2</u>. Comparison of baseline characteristics of persons who received a booster dose mRNA COVID-19 vaccine and their comparators who did not, before and after matching, demonstrate excellent balance after matching

a. Absolute standardized mean difference and variance ratio of baseline characteristics between booster dose mRNA vaccination recipients versus no booster dose shown for the raw (green dots) and matched (orange dots) data demonstrate balance after matching.

Prior to matching, the absolute standardized difference in baseline characteristics between the 3rd dose and no 3rd dose groups ranged from 0.003-0.162 with a median of 0.060 (IQR: 0.040-0.089). After matching, the absolute standardized differences ranged from 0.000-0.016 with a median of 0.001 (IQR: 0.002-0.011).

b. Cumulative distribution of propensity score between booster dose mRNA vaccination recipients versus no booster dose shown for the raw and matched data demonstrate balance after matching.

Supplementary Figure 3. Kaplan-Meier curves comparing persons who received a booster mRNA COVID-19 vaccine versus their matched counterparts who did not with respect to the cumulative incidence (%) and 95% confidence intervals of SARS-CoV-2 infection (a) (b), SARS-CoV-2-related hospitalization (c)(d) and SARS-CoV-2-related death (e)(f). Results are shown separately for booster vaccination with BNT162b2 (a,c,e) and mRNA-1273(b,d,f)
