178 This study was performed over one month in 2017 on an inpatient unit for haematological<br>179 malignancies, split into two wards (A and B). VREfm rectal screening was performed on al 179 malignancies, split into two wards (A and B). VREfm rectal screening was performed on all new admissions and any inpatients with febrile episodes to inform patient placement and<br>181 antimicrobial administration. There was significant overlap between patient stays with some<br>182 patients moving between the two study antimicrobial administration. There was significant overlap between patient stays with some<br>182 patients moving between the two study wards or to other wards in the hospital (Figure 1).<br>183 Patients were cohorted or placed patients moving between the two study wards or to other wards in the hospital (Figure 1).<br>183 Patients were cohorted or placed in single rooms when colonised with VREfm or other ale<br>184 pathogens. However, not all rooms ha 183 Patients were cohorted or placed in single rooms when colonised with VREfm or other alert<br>184 pathogens. However, not all rooms had ensuite bathroom facilities so risk of VREfm<br>185 transmission remained. At the time of 184 pathogens. However, not all rooms had ensuite bathroom facilities so risk of VREfm<br>185 transmission remained. At the time of the study, surveillance systems in the hospital<br>186 detected any suspected VREfm outbreak wit 185 transmission remained. At the time of the study, surveillance systems in the hospital had not<br>186 detected any suspected VREfm outbreak within the study population.<br>187 186 detected any suspected VREfm outbreak within the study population.<br>187<br>188 Results of VREfm Screening

188<br>189

188 *Results of VREfm Screening*  I89 In total, 45 rectal swabs from 27 patients were screened for VREfm. Of these, 18 samples from<br>190 13 patients were VREfm positive (Table 1). Three (23.1%) colonised patients developed VREfm<br>191 bacteraemia 9, 24, or 46 190 13 patients were VREfm positive (Table 1). Three (23.1%) colonised patients developed VREfm<br>191 bacteraemia 9, 24, or 46 days after being identified as VREfm carriers. We applied our sampling<br>192 strategy to 16 rectal bacteraemia 9, 24, or 46 days after being identified as VREfm carriers. We applied our sampling<br>192 strategy to 16 rectal screens generating 224 isolates from 11 patients, and five blood cultures<br>193 (five isolates) from t strategy to 16 rectal screens generating 224 isolates from 11 patients, and five blood cultures<br>193 (five isolates) from two patients yielding a total of 229 isolates. Two rectal swabs and one bloo<br>194 culture were not ava 193 (five isolates) from two patients yielding a total of 229 isolates. Two rectal swabs and one blood<br>194 culture were not available for further study. Most patients were female, the median age was 66<br>195 years, and a ran culture were not available for further study. Most patients were female, the median age was 66<br>195 years, and a range of primary diagnoses were present (Table 1). Most colonised patients had<br>196 received antibiotics in the 195 years, and a range of primary diagnoses were present (Table 1). Most colonised patients had<br>196 received antibiotics in the preceding six months and 30% had received vancomycin (Table 1).<br>197 196 received antibiotics in the preceding six months and 30% had received vancomycin (Table 1).<br>197<br>198 Simultaneous carriage of multiple VREfm strains

197<br>198<br>199

198 *Simultaneous carriage of multiple VREfm strains In silico* MLST typing using short reads from all 229 genomes showed ST80 (n=130), ST1424<br>200 (n=97), ST789 (n=1), and ST1659 (n=1) from the hospital-associated clade A1<sup>60</sup> were present<br>201 (Table 2). Multiple STs we (n=97), ST789 (n=1), and ST1659 (n=1) from the hospital-associated clade A1<sup>60</sup> were present<br>
201 (Table 2). Multiple STs were detected in three (27%) samples. Sample VRED06 from patient<br>
202 P49 contained 10 (71.4%) ST80 201 (Table 2). Multiple STs were detected in three (27%) samples. Sample VRED06 from patient<br>202 P49 contained 10 (71.4%) ST80, three (21.4%) ST1424, and one (7.1%) ST789 isolate; sample<br>203 VRED07 from P14 contained 10 (7 203 VRED07 from P14 contained 10 (71.4%) ST1424 and four (28.6%) ST80 isolates; sample<br>204 VRED11 from P50 contained 13 (92.9%) ST1424 and one (7.1%) ST1659 isolate. A furthe 204 VRED11 from P50 contained 13 (92.9%) ST1424 and one (7.1%) ST1659 isolate. A further<br>205 Frectal swab sample from P49 collected two days after VRED06 contained only ST1424, and 204 VRED11 from P50 contained 13 (92.9%) ST1424 and one (7.1%) ST1659 isolate. A further<br>205 Frectal swab sample from P49 collected two days after VRED06 contained only ST1424, and 205 rectal swab sample from P49 collected two days after VRED06 contained only ST1424, and a

blood culture collected nine days later also contained ST1424. P9 had three rectal swab<br>207 samples collected over 11 days and had positive blood cultures one month later, all samples<br>208 contained ST80 only. Our finding o samples collected over 11 days and had positive blood cultures one month later, all samples<br>208 contained ST80 only. Our finding of multiple strains in 27% of patients is in line with recent<br>209 studies showing up to half contained ST80 only. Our finding of multiple strains in 27% of patients is in line with recent<br>209 studies showing up to half of patients carry 2-4 different *E. faecium* strains, and within-patie<br>210 diversity varies over 209 studies showing up to half of patients carry 2-4 different *E. faecium* strains, and within-patient diversity varies over time.<sup>20,24,61,62</sup> 210<br>211

212<br>213 212 *Genomic population structure of VREfm suggests recent transmission events*<br>213 The chromosomes of the two strain-specific genome assemblies (Tabl<br>214 as references for short-read mapping within ea The chromosomes of the two strain-specific genome assemblies (Table S1) were used<br>214 as references for short-read mapping within each sequence type. Within-patient diversity was<br>215 Iow when genomes of the same sequence t as references for short-read mapping within each sequence type. Within-patient diversity was<br>215 bow when genomes of the same sequence type were compared, generally differing by zero<br>216 SNPs and a maximum pairwise differe low when genomes of the same sequence type were compared, generally differing by zero<br>216 SNPs and a maximum pairwise difference of 3 SNPs (Table 2). Similarly, insertions, deletio<br>217 and plasmids were usually shared in g SNPs and a maximum pairwise difference of 3 SNPs (Table 2). Similarly, insertions, deletions,<br>217 and plasmids were usually shared in genomes from the same patient. However, the presence of<br>218 DEL3 (12 bp non-coding delet and plasmids were usually shared in genomes from the same patient. However, the presence of<br>218 DEL3 (12 bp non-coding deletion) and DEL4 (11 bp deletion in a solute binding protein) were<br>219 variable within 24 ST80 genome DEL3 (12 bp non-coding deletion) and DEL4 (11 bp deletion in a solute binding protein) were<br>219 variable within 24 ST80 genomes from P20 with 0-2 differentiating SNPs (Figure 2). In genom<br>220 from P9 p1 VRED06-10 and p3 VR variable within 24 ST80 genomes from P20 with 0-2 differentiating SNPs (Figure 2). In genomes<br>220 from P9 p1\_VRED06-10 and p3\_VRED06-10 were variably detected despite most genomes<br>221 having no differentiating SNPs (Figure 220 from P9 p1\_VRED06-10 and p3\_VRED06-10 were variably detected despite most genomes<br>221 having no differentiating SNPs (Figure 2). Where multiple samples from the same patient were<br>222 collected over time we found low (0 having no differentiating SNPs (Figure 2). Where multiple samples from the same patient were<br>
collected over time we found low (0-3 SNPs) accumulation of SNPs and no pattern in the<br>
prevalence of other genomic variants. Es collected over time we found low (0-3 SNPs) accumulation of SNPs and no pattern in the<br>223 prevalence of other genomic variants. Estimates of diversification rates in *E. faecium* from<br>224 colony sampling of national isola 223 prevalence of other genomic variants. Estimates of diversification rates in *E. faecium* from single colony sampling of national isolate collections suggest 7 mutations per year, $^{63}$ 224 other studies of longitudinal within-patient diversification have estimated higher rates of 12.6 – 128 mutations<br>226 per year.<sup>20,22,23</sup> The low SNP diversity identified in our one-month collection of carriage isolate<br>227 is in keeping wit per year.<sup>20,22,23</sup> The low SNP diversity identified in our one-month collection of carriage isolates<br>227 is in keeping with these estimated mutation rates.<br>228 The ST80 genomes formed a well-structured population with fiv

is in keeping with these estimated mutation rates.<br>228 The ST80 genomes formed a well-structure<br>229 Separated by >10 SNPs (Figure 2). Clustered gene The ST80 genomes formed a well-structured population with five clear clusters each<br>229 separated by >10 SNPs (Figure 2). Clustered genomes differed by 0-2 SNPs and were most<br>230 from individual patients although two cluste separated by >10 SNPs (Figure 2). Clustered genomes differed by 0-2 SNPs and were mostly<br>230 from individual patients although two clusters included genomes from two different patients<br>231 (patients P7 and P33, and P2 and 230 from individual patients although two clusters included genomes from two different patients<br>231 (patients P7 and P33, and P2 and P9). All the reference plasmids were detected in the P7 a 231 (patients P7 and P33, and P2 and P9). All the reference plasmids were detected in the P7 and<br>
231 (patients P7 and P33, and P2 and P9). All the reference plasmids were detected in the P7 and

232 P33 genomes and there were two insertions detected in three genomes. There was variation in<br>233 detection of p1\_VRED06-10 and p3\_VRED06-10 plasmids within P9 genomes, although in P2<br>234 denomes all plasmids were detect detection of p1\_VRED06-10 and p3\_VRED06-10 plasmids within P9 genomes, although in P2<br>234 genomes all plasmids were detected.<br>235 Mapping of the ST1424 genomes showed a much more homogeneous population than

234 genomes all plasmids were detected.<br>235 Mapping of the ST1424 genom<br>236 in ST80 (Figure 3). Of the 97 ST1424 Mapping of the ST1424 genomes showed a much more homogeneous population than<br>236 in ST80 (Figure 3). Of the 97 ST1424 genomes, 69 had no SNPs and the remaining 28 had 1-2<br>237 SNPs differentiating them from the rest of the in ST80 (Figure 3). Of the 97 ST1424 genomes, 69 had no SNPs and the remaining 28 had 1-2<br>237 SNPs differentiating them from the rest of the collection. The SNPs that were detected did not<br>238 lead to any clear clustering 238 Lead to any clear clustering of genomes, except for the 14 genomes from P6 which all carried a<br>239 SNP in a penicillin-binding protein which differentiated them from the other ST1424 genomes. lead to any clear clustering of genomes, except for the 14 genomes from P6 which all carried a<br>239 SNP in a penicillin-binding protein which differentiated them from the other ST1424 genomes.<br>240 Two of the P6 genomes had SNP in a penicillin-binding protein which differentiated them from the other ST1424 genomes.<br>240 Two of the P6 genomes had further independent SNPs (one each) and another genome had<br>241 Iost p1 VRED06-02. No insertions wer Two of the P6 genomes had further independent SNPs (one each) and another genome had<br>241 Iost p1\_VRED06-02. No insertions were detected in the ST1424 collection, and of the six<br>242 Ideletions found five were only in genome lost p1\_VRED06-02. No insertions were detected in the ST1424 collection, and of the six<br>242 deletions found five were only in genomes from P49. p6\_VRED06-02 was not detected in<br>243 P24, 14 P50, and two P49 genomes, while p deletions found five were only in genomes from P49. p6\_VRED06-02 was not detected in 14<br>243 P24, 14 P50, and two P49 genomes, while p1\_VRED06-02 was note detected in five genome<br>244 from three patients. 243 P24, 14 P50, and two P49 genomes, while p1\_VRED06-02 was note detected in five genomes<br>244 from three patients.<br>245 244 from three patients.<br>245<br>246 Analysis of multiple VREfm colonies supports transmission resolution

247 247 A transmission network was constructed considering the phylogenetic placement of all 14<br>248 Colony picks in each sample (Figure 4). The network supports transmission of ST80 betwe 248 Colony picks in each sample (Figure 4). The network supports transmission of ST80 between P2<br>249 Cand P9, and between P7 and P33, with P20 not linked to transmission. Epidemiological data 249 and P9, and between P7 and P33, with P20 not linked to transmission. Epidemiological data<br>250 supports transmission from P33 to P7 on Ward B, as P33 screened negative early in their 250 supports transmission from P33 to P7 on Ward B, as P33 screened negative early in their<br>251 admission and then screened positive six days after P7 (Figure 1, Figure 4). P9 and P2 supports transmission from P33 to P7 on Ward B, as P33 screened negative early in their<br>251 admission and then screened positive six days after P7 (Figure 1, Figure 4). P9 and P2<br>252 screened positive on the same dav - no 251 admission and then screened positive six days after P7 (Figure 1, Figure 4). P9 and P2<br>252 screened positive on the same day - no shared rooms or bed spaces were identified as<br>253 P2's first day on Ward B so it is uncl screened positive on the same day - no shared rooms or bed spaces were identified as this was<br>253 P2's first day on Ward B so it is unclear where or when transmission may have occurred (Figure<br>254 1, Figure S1). P20 had tw 254 1, Figure S1). P20 had two admissions during the study period, was negative at the end of first<br>255 admission then screened positive on re-admission suggesting they may have become colonised 1, Figure S1). P20 had two admissions during the study period, was negative at the end of first<br>255 admission then screened positive on re-admission suggesting they may have become colonise<br>256 outside of the hospital. 255 admission then screened positive on re-admission suggesting they may have become colonised<br>256 outside of the hospital.<br> 256 outside of the hospital.

257 All ST1424 patients clustered together with P34 strongly linked to all patients and likely<br>258 direct transmission to P6 (Figure 4). P34 was the first ST1424 identified on Ward B, P49 was<br>259 positive six days later (h direct transmission to P6 (Figure 4). P34 was the first ST1424 identified on Ward B, P49 was<br>259 positive six days later (having been negative earlier in admission), P14 was positive two days<br>260 after that, and P24 was po 259 positive six days later (having been negative earlier in admission), P14 was positive two days<br>260 after that, and P24 was positive 9 days subsequently (Figure 1). P14 and P49 had ST1424 an<br>261 ST80 in carriage samples after that, and P24 was positive 9 days subsequently (Figure 1). P14 and P49 had ST1424 and<br>261 ST80 in carriage samples, we did not identify sharing of the ST80 lineages in these patients<br>262 Suggesting there was no direc 261 ST80 in carriage samples, we did not identify sharing of the ST80 lineages in these patients<br>262 suggesting there was no direct transmission between these two patients. On Ward A, P50<br>263 screened positive with ST1424 suggesting there was no direct transmission between these two patients. On Ward A, P50<br>263 screened positive with ST1424 and ST1659 on day two of admission and P6 screened positive<br>264 for ST1424 on day six. The ST1424 pop screened positive with ST1424 and ST1659 on day two of admission and P6 screened positive<br>264 for ST1424 on day six. The ST1424 populations in P6 and P50 may derive from different hosts<br>265 with P6 genomes all having a sin for ST1424 on day six. The ST1424 populations in P6 and P50 may derive from different hosts<br>265 with P6 genomes all having a single SNP and P50 genomes having multiple different SNPs and<br>266 lack the p6 VRED06-02 plasmid ( with P6 genomes all having a single SNP and P50 genomes having multiple different SNPs and<br>266 Lack the p6\_VRED06-02 plasmid (Figures 3 and 4). P34 and P50 shared time on Ward A early<br>267 Lin the study before either were k lack the p6\_VRED06-02 plasmid (Figures 3 and 4). P34 and P50 shared time on Ward A early<br>267 in the study before either were known to be VREfm positive, but there is very limited overlap in<br>268 time between P34 and P6 whil in the study before either were known to be VREfm positive, but there is very limited overlap i<br>268 time between P34 and P6 while both were in different wards (Figure 1). None of the patients<br>269 with ST1424 shared a room time between P34 and P6 while both were in different wards (Figure 1). None of the patients<br>269 with ST1424 shared a room or used a bed space previously used by an identified ST1424-<br>270 positive carrier during their stay with ST1424 shared a room or used a bed space previously used by an identified ST1424-<br>270 positive carrier during their stay (Figure S1).<br>271 Analysing less than 14 colonies per sample produced fewer transmission links an

positive carrier during their stay (Figure S1).<br>271 Analysing less than 14 colonies per sample produced fewer transmission links and lower<br>272 confidence (Table S2, Figure S2). Sequencing more than 14 colonies would improv Analysing less than 14 colonies per sample produced fewer transmission links and lower<br>272 confidence (Table S2, Figure S2). Sequencing more than 14 colonies would improve the<br>273 detection of minor variants while increasi confidence (Table S2, Figure S2). Sequencing more than 14 colonies would improve the<br>273 detection of minor variants while increasing costs and turnaround time. There was low wit<br>274 patient diversity in most patients in o detection of minor variants while increasing costs and turnaround time. There was low withir<br>274 patient diversity in most patients in our study so this approach may not be required in every<br>275 case. Alternatively, strain patient diversity in most patients in our study so this approach may not be required in every<br>275 case. Alternatively, strain-resolved metagenomics directly on clinical samples or sweeps of<br>276 selective culture growth may case. Alternatively, strain-resolved metagenomics directly on clinical samples or sweeps of<br>276 selective culture growth may be more feasible.<sup>64–66</sup> Further work is required to determine the<br>277 optimum sampling strategy selective culture growth may be more feasible.<sup>64–66</sup> selective culture growth may be more feasible.<sup>64–66</sup> Further work is required to determine the<br>277 optimum sampling strategy to support infection prevention and control investigations in<br>278 healthcare settings. 277 optimum sampling strategy to support infection prevention and control investigations in<br>278 healthcare settings.<br>279

278 healthcare settings.<br>279<br>280 Plasmids were most 279<br>280 280 *Plasmids were mostly ST-specific* 

281 VRED06-02 (ST1424 reference) contained seven plasmids, and VRED06-10 (ST80 reference)<br>282 contained five plasmids. Plasmids in the two genomes were generally distinct, suggesting<br>283 limited sharing between STs within contained five plasmids. Plasmids in the two genomes were generally distinct, suggesting<br>283 limited sharing between STs within P49 (Table S3).<br>284 We sought to identify carriage of similar plasmids in the entire collectio

283 limited sharing between STs within P49 (Table S3).<br>284 We sought to identify carriage of similar plas<br>285 mapping (Table S4). Most plasmids were ST-specifi We sought to identify carriage of similar plasmids in the entire collection by short read<br>285 mapping (Table S4). Most plasmids were ST-specific with few examples of ST1424 genomes<br>286 carrying plasmids from the ST80 refer mapping (Table S4). Most plasmids were ST-specific with few examples of ST1424 genomes<br>286 carrying plasmids from the ST80 reference, and *vice versa*. However, all ST80 genomes from<br>287 P7 and P33 carried p7 VRED06-02 fro 287 P7 and P33 carried p7\_VRED06-02 from ST1424, and almost all genomes appeared to carry<br>288 p4 VRED06-10. We believe the hits against the ST1424 genomes are due to cross-mapping of 287 P7 and P33 carried p7\_VRED06-02 from ST1424, and almost all genomes appeared to carry<br>288 p4\_VRED06-10. We believe the hits against the ST1424 genomes are due to cross-mapping<br>289 reads from the related p4\_VRED06-02 (T p4\_VRED06-10. We believe the hits against the ST1424 genomes are due to cross-mapping of<br>289 preads from the related p4\_VRED06-02 (Table S3). P7\_VRED06-02 is unrelated to others in the<br>290 prollection (Table S3), but no cl reads from the related p4\_VRED06-02 (Table S3). P7\_VRED06-02 is unrelated to others in the<br>290 collection (Table S3), but no close links to any ST1424-positive patients were identified for P7<br>291 and P33 (Figure 4). collection (Table S3), but no close links to any ST1424-positive patients were identified for P7<br>291 and P33 (Figure 4).<br>292

<sup>594</sup>**Figure 1** – Patient timeline. Each row denotes the location of a patient during admission, blocks 595 denote hospital stay, circles denote VREfm cultures, stars denote bloodstream isolates, dotted 596 lines indicate the start and end of prospective collection of screening isolates for this study. This 597 study was undertaken mainly within Wards A and B, although patients were moved to different 598 wards within the hospital during their stay and were often admitted through the assessment unit. 599

<sup>601</sup>**Figure 2** – Phylogeny of ST80 isolates showing structured population with three patient specific

602 clusters and two clusters indicating putative patient-patient transmission of VREfm. All ST80

603 isolates (n=130) mapped to VRED06-10 chromosome and phylogeny built on SNP sites (n=96)

604 after removal of putative transposable and recombinant regions. Tree unrooted.

Reference sequence 606

- <sup>607</sup>**Figure 3** Unrooted phylogeny of ST1424 genomes showing homogeneous population
- 608 suggestive of recent transmission outbreak. ST1424 genomes (n=97) mapped to VRED06-02
- 609 chromosome and phylogeny built on SNP sites (n=13) after removal of putative transposable
- 610 and recombinant regions. Tree unrooted.

613

<sup>614</sup>**Figure 4** – Phyloscanner transmission network. Each patient is represented by a node coloured

615 by detection of the two outbreak STs. Edge thickness corresponds to fraction of Phyloscanner

616 trees with given relationship, relationship fraction is printed alongside each edge, and edge

617 colour based on type of relationship (orange, direct transmission; blue, transmission but

618 direction unclear).

<sup>621</sup>**Figure 5** – Detection of antimicrobial resistance genes. Panels represent different patients; 622 resistance genes are plotted on the y-axis and isolates on the x-axis. Presence of a gene is 623 represented by a filled square and coloured based on the MLST of the genome.
