25 **KEYWORDS**

Polychlorinated biphenyls, DNA methylation, placenta, autism spectrum disorders, WGCNA,
 whole genome bisulfite sequencing

29 ABBREVIATIONS

- 30 PCB polychlorinated biphenyl; WGBS whole genome bisulfite sequencing; ASD autism
- 31 spectrum disorder; TD typical development; DMR differentially methylated region; PMD partially
- 32 methylated domain; WGCNA weighted gene correlation network analysis
- 33

34 ABSTRACT

35

36 Background:

- 37 Gestational exposure to polychlorinated biphenyls (PCBs) has been associated with elevated risk 38 for neurodevelopmental disorders. The mechanism of risk is unclear but may involve placental 39 epigenetics. Prior studies have associated differential placental DNA methylation with maternal
- 40 PCB exposure or with increased risk of autism spectrum disorder (ASD). However, sequencing-
- 40 PCB exposure of with increased lisk of autism spectrum disorder (ASD). However, sequencing-
- 41 based placental methylomes have not previously been tested for simultaneous associations with
- 42 maternal PCB levels and child neurodevelopmental outcomes.
- 43

44 **Objectives:**

- 45 We aimed to identify placental DNA methylation patterns associated with maternal PCB levels
- and child neurodevelopmental outcomes in the high-risk ASD MARBLES cohort.
- 47

48 Methods:

- 49 We measured 209 PCB congeners in 104 maternal serum samples collected at delivery. We
- 50 identified networks of DNA methylation from 147 placenta samples using the Comethyl R

- 51 package, which performs weighted gene correlation network analysis for whole genome bisulfite
- 52 sequencing data. We tested placental DNA methylation modules for association with maternal 53 serum PCB levels, child neurodevelopment, and other participant traits.
- 54 55 **Results**:

56 PCBs 153 + 168, 170, 180 + 193, and 187 were detected in over 50% of maternal serum samples 57 and were highly correlated with one another. Consistent with previous findings, maternal age was 58 the strongest predictor of serum PCB levels, alongside year of sample collection, pre-pregnancy 59 BMI, and polyunsaturated fatty acid levels. Twenty seven modules of placental DNA methylation 60 were identified, including five which significantly correlated with one or more PCBs, and four which 61 correlated with child neurodevelopment. Two modules associated with maternal PCB levels as 62 well as child neurodevelopment, and mapped to CSMD1 and AUTS2, genes previously implicated 63 in ASD and identified as differentially methylated regions in mouse brain and placenta following 64 gestational PCB exposure.

65

66 **Conclusions**:

Placental DNA co-methylation modules were associated with maternal PCBs and child
 neurodevelopment. Methylation of *CSMD1* and *AUTS2* could potentially be mechanistically
 involved in ASD risk following maternal PCB exposure.

74 **1.INTRODUCTION**

75

76 Polychlorinated biphenyls (PCBs) are a class of 209 synthetic compounds that are ubiquitous in 77 the environment and harmful to human health. Prior to their international ban in 2001 (Stockholm 78 Convention, 2001), PCBs were commonly used in industrial processes and consumer products, 79 such as plastics, paint, and pesticides. Over 20 years later, PCBs continue to be released into 80 the environment from spills/improper disposal, degradation of PCB-containing materials, and 81 inadvertent production (Grimm et al., 2015; Hu & Hornbuckle, 2010), resulting in their presence 82 throughout our environment, from oceans (Wagner et al., 2019), soil (reviewed in (Wolska et al., 83 2014)) and landfills (reviewed in (Gabryszewska & Gworek, 2021), to human food products 84 (Saktrakulkla et al., 2020) and indoor air, including air in schools (reviewed in (Herrick et al., 85 2016)). PCBs are detectable and persistent in many marine (reviewed in (Domingo & Bocio, 86 2007)) and land animal species (reviewed in (Rhind, 2002)), as well as in humans, including 87 pregnant people (Granillo et al., 2019) and newborns (Berghuis et al., 2013; Mori et al., 2014; Yu 88 et al., 2019). Adult exposure to PCBs by inhalation, absorption through skin, or consumption of 89 contaminated foods such as dairy, meat and fish, increases risk for many diseases, including 90 cancer (reviewed in (Leng et al., 2016; Wan et al., 2022)), cardiovascular disease (reviewed in 91 (Gupta et al., 2018)) and reproductive abnormalities (reviewed in (Rattan et al., 2017)). Of 92 significant concern, fetal exposure to PCBs via maternal blood has been associated with adverse 93 health outcomes in the offspring, including increased risk of neurodevelopmental disorders such 94 as autism spectrum disorder (ASD) (Panesar et al., 2020; Pessah et al., 2019).

95

96 ASD is a group of neurodevelopmental disorders characterized by impairments in social 97 reciprocity and communication, restrictive interests, and repetitive behaviors. Risk for and 98 protection from ASD is influenced by a wide variety of genetic and environmental factors as well 99 as gene by environment interactions (reviewed in (Chaste & Leboyer, 2012; Cheroni et al., 2020; 100 Lyall, Croen, Daniels, et al., 2017)). Diagnoses of ASD have been increasing over the past several 101 decades and are currently estimated to affect approximately 1 in 44 children in the United States 102 (Maenner, 2021). These sobering statistics are a primary premise for the hypothesis that 103 gestational exposure to environmental chemicals influence individual risk for ASD. However, the 104 mechanisms by which environmental factors influence risk remain controversial (Lein, 2015).

105

106 Epigenetic marks are widely posited as one mechanism mediating gene by environment 107 interactions that confer ASD risk (Lein, 2015; Panesar et al., 2020) with the placental epigenome 108 functioning as a potential biological substrate (Zhu et al., 2022). The placenta is a fetal tissue 109 that invades the uterus and is responsible for providing nutrients and oxygen to the fetus as well 110 as removing waste. While the placenta filters out many toxic chemicals from the maternal 111 bloodstream, small lipophilic chemicals, such as PCBs, can cross the placental barrier and enter 112 the bloodstream of the fetus (Guvenius et al., 2003; Park et al., 2008; Soechitram et al., 2004). 113 Indeed, PCB levels in human placenta have been found to significantly correlate with those in 114 maternal blood and umbilical cord blood (Jeong et al., 2018). This placental exposure can alter 115 patterns of DNA methylation, a tissue-specific epigenetic mark that is influenced by both genetic 116 and environmental factors. DNA methylation marks are dynamic during development when they 117 are being established and then remain mostly stable, affecting gene expression throughout the 118 lifetime (Moore et al., 2013).

119

120 Recently, differential DNA methylation has been identified in human placenta and umbilical cord

- blood of individuals later diagnosed with ASD (Mordaunt et al., 2020; Zhu et al., 2022). Moreover,
- maternal PCB levels have been associated with altered DNA methylation in human placenta (Ouidir et al., 2020) and in mouse placenta and fetal brain (Laufer et al., 2022). Both Ouidir et al.
- 123 (Ouidir et al., 2020) and in mouse placenta and fetal brain (Laufer et al., 2022). Both Ouidir et al. 124 and Laufer et al. found enrichment for pathways related to neurodevelopment and neuronal/brain

4

functions. However, no human study to date has examined associations between maternal PCB exposure, whole-epigenome placenta DNA methylation, and offspring neurodevelopmental outcomes.

128

129 In this study, we measured 209 130 PCB congeners from 104 131 samples of maternal serum 132 collected delivery and at 133 analyzed DNA methylation 134 networks from 147 placental 135 samples using weighted gene 136 network analysis correlation 137 (WGCNA) (Langfelder & 138 Horvath, 2008) (Figure 1). We 139 correlated placental DNA 140 methylation modules with 141 maternal serum PCB values, as 142 well as participant traits related 143 to child neurodevelopment, 144 maternal health, demographic 145 factors, and birth factors. Using 146 this approach, we identified 147 known ASD risk genes CSMD1 148 and AUTS2 and other potential 149 biomarkers of PCB exposure 150 relevant to neurodevelopment. 151

Eligible MARBLES mother-child pairs enrolled between 2006 and 2016 (N = 397) Maternal serum Placental samples samples with PCB with whole genome measurements bisulfite sequencing (N = 104, ASD = 42,(N = 147, ASD = 52,TD = 48, non-TD = 13, TD = 74, non-TD = 21) no diagnosis = 1) Overlap between placenta and maternal serum (N = 95, ASD = 41, TD = 42, non-TD = 12) Figure 1. Sample inclusion from the MARBLES cohort

- 152 **2. METHODS**
- 153

154 **2.1. Study Population**

155

156 **2.1.1. MARBLES and EARLI cohorts**

157 This study included mother-child pairs that were enrolled in the Markers of Autism Risk in Babies 158 - Learning Early Signs (MARBLES) study from 2006-2016. As previously described (Hertz-159 Picciotto et al., 2018), MARBLES enrolls mothers in northern California who already have a 160 biological child with ASD and are therefore at increased risk of delivering another child who will 161 develop ASD. Enrollment in the MARBLES study required families to meet the following criteria: 162 1) the mother or father already had a biological child diagnosed with ASD, and the mother was 2) 163 at least 18 years of age; 3) already pregnant or planning to become pregnant; 4) living within a 2-164 hour drive of the Davis/Sacramento area; and 5) proficient in English. This study used 104 165 maternal serum samples from MARLBES for PCB analysis and 147 placentas (after quality 166 control) from MARBLES for DNA methylation analysis; 95 of the serum and placenta samples 167 came from a mother-fetus pair.

168

This study uses an independent replication cohort from the Early Autism Risk Longitudinal Investigation (EARLI) to validate results from DNA methylation analysis. Similarly to MARBLES and previously described elsewhere (Newschaffer et al., 2012), EARLI enrolls mothers who already have a biological child with ASD. Families were recruited from Drexel/Children's Hospital of Philadelphia, Johns Hopkins/Kennedy Krieger Institute, Kaiser Permanente Northern California, and University of California, Davis. Enrollment in the EARLI study required families to meet the following criteria: 1) the mother or father already had a biological child diagnosed with

placentas from EARLI to confirm the preservation and quality of the DNA co-methylation modules.

ASD, and the mother was 2) at least 18 years of age; 3) less than 29 weeks pregnant; 4) living within a 2-hour drive of the study site; and 5) proficient in English or Spanish. This study used 47

- 178 179
- 180 **2.1.2.** Diagnostic classification for autism spectrum disorder

181 Children enrolled in MARBLES and EARLI were clinically assessed for autism spectrum disorder 182 (ASD) around 36 months of age by professional examiners. Diagnosis was based on the Autism 183 Diagnostic Observation Schedule (ADOS) (Lord et al., 2000), Autism Diagnostic Interview -184 Revised (ADI-R) (Lord et al., 1994), and Mullen Scales of Early Learning (MSEL) (Mullen, 1995). 185 ADOS is a standardized assessment tool that uses structured and semi-structured activities that 186 allow the examiner to evaluate communication skills, social interaction, and imaginative use of 187 materials. The ADOS module 2 scores range from 0 to 28, with scores equal to or higher than 7 188 meeting the cut-off for ASD. ADI-R is a structured interview with a parent or caregiver to discuss 189 the developmental history and current behavior of the child; this interview can be useful to 190 distinguish ASD from other developmental disorders. MSEL is a standardized evaluation whereby 191 the child completes a set of motor, visual, and language tasks which are assessed by the 192 examiner. MSEL has four subscale scores (fine motor, expressive language, receptive language, 193 and visual reception) as well as an overall early learning composite score, which is referred to as 194 Mullen Score in this manuscript. The composite score range is 49 to 155, with scores below 70 195 indicating neurodevelopmental delays.

196

197 Based on ADOS and MSEL scores, children in MARBLES and EARLI were categorized into three 198 outcome groups: ASD, typical development (TD), and non-typical development (non-199 TD)(Chawarska et al., 2014; Ozonoff et al., 2014; Schmidt et al., 2019). Children classified in the 200 ASD group had ADOS scores above the cut-off and met the DSM-5 criteria for ASD. Children 201 classified in the TD group had MSEL scores that were all within 2 SD and no more than one MSEL 202 subscale score that was 1.5 SD below the normative mean, as well as ADOS scores that were 3 203 or more points below the cut-off score for ASD. Children that met the criteria for neither ASD nor 204 TD were classified as non-TD; these children had low MSEL scores (two or more MSEL subscale 205 scores more than 1.5 SD below the normative mean or at least one MSEL subscale score more 206 than 2 SD below the normative mean) and/or high ADOS scores (within 3 points of the cut-off 207 score for ASD).

208

209 **2.1.3.** Participant traits

MARBLES participants provided demographic, nutritional, environmental, pregnancy, and medical information through telephone-assisted interviews and mailed questionnaires. We selected particular traits of interest, coded them numerically for analysis, and grouped them into four categories for ease of discussion: demographics, maternal health, birth factors, and child neurodevelopment. Information on some traits was not available for all participants, in which case the data were removed and statistical analyses performed on the data available.

216

217 Demographic traits evaluated include both parents' birthplace (California/not California), race 218 (white/non-white), ethnicity (Hispanic/non-Hispanic), education level (less than high school/high 219 school diploma or GED/some college/Bachelor's degree/graduate or professional degree), and 220 age at time of the child's birth, as well as home ownership (renter/owner), delivery payer 221 (public/private insurance at time of child delivery), and sex assigned at birth of the enrolled child 222 (male/female). Maternal health factors evaluated include diagnosis of gestational diabetes 223 (yes/no), pre-eclampsia (yes/no), or chronic hypertension (yes/no), as well as maternal BMI pre-224 pregnancy (continuous; calculated from weight and height), maternal plasma polyunsaturated 225 fatty acid (PUFA) levels (DPA + DHA + EPA measured in maternal serum), maternal omega 3s 226 (high/low), prenatal vitamin use in month 1 of pregnancy (yes/no), and maternal smoking during

pregnancy (yes/no). PUFA and omega 3 data have been previously reported (Huang et al., 2020). 227 228 Birth factors evaluated include delivery method (vaginal/C-section), birth month, birth season (fall, 229 winter, spring, summer), birth year (2006-2016), parity (number of pregnancies over 20 weeks 230 gestation prior to this pregnancy), Apgar score at 5 minutes, Apgar score at 1 minute, birth weight 231 (grams), birth length (cm), and gestational age at delivery (number of weeks into pregnancy when 232 delivery occurs). Factors related to child neurodevelopment include age at which ADOS and 233 MSEL tests were performed, MSEL composite score, ADOS comparison score, and diagnosis of 234 ASD (ASD, TD, non-TD).

235

236 Participant traits were correlated with one another using Pearson and Spearman correlations and 237 p-values were corrected for multiple testing by FDR using the psych R package v2.2.5 corr.test 238 function (Revelle, 2022). Pearson measures linear correlation, whereas Spearman measures 239 monotonic correlation, providing less restrictive but also less powerful results. Given the structural 240 diversity of our data, we elected to use both correlation measures to capture as many potential 241 relationships as possible. We adjusted p-values by FDR due to its power to detect true positives 242 (Benjamini & Hochberg, 1995, 2000; Chen et al., 2010; Korthauer et al., 2019). GraphPad Prism 243 version 9.4.1, GraphPad Software, San Diego, California USA, www.graphpad.com, chi-squared 244 test was used to test if prenatal vitamin use differed among ASD, non-TD, and TD diagnostic 245 groups, while one-way ANOVA and Tukey's multiple comparisons test were used to test 246 differences in MSEL scores across diagnostic groups.

247 248

248 2.2. PCB measurements and analysis249

250 **2.2.1. Serum collection and storage**

251 Maternal serum was collected in red-top serum-separator vacutainers at time of delivery and 252 processed with centrifugation within 4 hours if possible, and stored frozen at -80 degrees 253 Fahrenheit. For this analysis, specimen aliquots were selected based on: having a minimum of 6 254 mL at delivery, child diagnosis data available, and a placenta specimen available for WGBS. 255 Serum aliquots were de-identified and shipped to the Analytical Core of the Iowa Superfund 256 Research Program frozen on dry ice. A pooled serum specimen from samples with ample volume 257 was created and included in each analysis run for quality assurance purposes. In this paper, PCB 258 congeners are referred to by their Ballschmitter and Zell number (US EPA, 2015).

259

260 **2.2.2. Chemicals and materials**

261 ¹³C-labeled PCBs, including ¹³C₁₂-PCB 3, ¹³C₁₂-PCB 15, ¹³C₁₂-PCB 31, ¹³C₁₂-PCB 52, ¹³C₁₂-PCB 262 118, ¹³C₁₂-PCB 153, ¹³C₁₂-PCB 180, ¹³C₁₂-PCB 194, ¹³C₁₂-PCB 206, and ¹³C₁₂-PCB 209, were 263 purchased from Cambridge Isotope Laboratories Inc. (Andover, Massachusetts, USA). 264 Deuterated PCB 30 (d₅-PCB 30) was obtained from C/D/N Isotopes (Pointe-Claire, Quebec, 265 Canada). A calibration standard containing all 209 PCB congeners and PCB 204 (internal 266 standard) were purchased from AccuStandard, Inc. (New Haven, Connecticut, USA). Unique 267 chemical identifiers of all 209 PCB congeners have been reported previously (Li, Westra, et al., 268 2022). Pesticide grade solvents, such as hexane and dichloromethane, were purchased from 269 Fisher Scientific (Pittsburgh, Pennsylvania, USA). The Standard Reference Material (SRM 1957) 270 was obtained from the National Institute of Standards and Technology (NIST, Gaithersburg, 271 Maryland, USA).

272 **2.2.3. Extraction of PCBs from maternal serum**

Serum samples were extracted and analyzed by gas chromatography-tandem mass spectrometry (GC-MS/MS) analysis using published procedures (Li, Hefti, et al., 2022; Marek et al., 2014;

275 Milanowski et al., 2010) in the Analytical Core of the Iowa Superfund Research Program. Briefly,

276 tissue samples were homogenized in 3 mL isopropanol. One mL of diethyl ether was added, and 277 samples were spiked with isotope-labeled PCB (5 ng/each in hexane). The tubes were inverted 278 for 5 minutes and centrifuged at 1,378 g for 5 minutes. The organic layer was transferred to a new 279 tube. The residue was re-extracted with 1 mL of isopropanol and 2.5 mL of hexane and diethyl 280 ether (9:1, vol/vol). The combined organic extracts were washed with 5 mL of phosphoric acid 281 (0.1 M in 0.9% agueous sodium chloride), and the agueous phase was re-extracted with 1 mL of 282 hexane and diethyl ether (9:1, v/v). The combined extracts were concentrated to near dryness 283 under a gentle stream of nitrogen, reconstituted in 4 mL of hexane, and 2 mL of a potassium 284 hydroxide solution (0.5 M in water-ethanol, 1:1, v/v) was added. After inversion for 5 min and 285 centrifugation at 1,378 g for 3 min, the organic phase was separated, and the bottom aqueous 286 phase was re-extracted with 3 mL of hexane. The combined organic phase contained the PCBs. 287 The PCB fraction was concentrated to ~ 0.5 mL under a gentle stream of nitrogen and passed 288 through a glass cartridge filled with 2 g of acidified silica gel (silica gel and concentrated sulfuric 289 acid, 2:1, w/w) with 0.2 g activated silica gel at the bottom and prewashed with 3 mL of hexane. 290 PCBs were eluted from the cartridge with 14 mL of hexane. The eluent was concentrated to 4 mL 291 and treated with 2 mL of concentrated sulfuric acid. After inversion for 5 min and centrifugation at 292 1,378 g for 3 min, the organic phase was collected, and the sulfuric acid layer was re-extracted 293 with 3 mL of hexane. The combined organic extract was concentrated to about 50 µL and 294 transferred to a glass autosampler vial with an insert. Before analysis, the sample was spiked with 295 the internal standards (d5-PCB 30 and PCB 204; 5 ng each in hexane).

296 **2.2.4. GC-MS/MS determination of PCBs**

297 PCB samples were analyzed on an Agilent GC system coupled with an Agilent 7000 Triple Quad 298 in the multiple reaction monitoring (MRM) mode on an SPB-Octyl capillary column (30 m length, 299 250 µm inner diameter, 0.25 µm film thickness; Sigma-Aldrich, St. Louis, Missouri, USA). The 300 following temperature program was used: 45 °C, hold for 2 min, 100 °C/min to 75 °C, hold for 5 301 min, 15 °C/min to 150 °C, hold for 1 min, 2.5 °C/min to 280 °C, and hold for 5 min. The injector 302 temperature program is as follows: start at 45 °C, hold for 0.06 min, 600 °C/min to 325 °C and 303 hold for 5 min. The transfer line temperature was 280 °C. Helium was used as a carrier gas with 304 a constant flow rate of 0.8 mL/min. The precursor-product ion transitions of all PCB analytes used 305 for the MS/MS analysis have been reported previously (Li, Hefti, et al., 2022).

306 **2.2.5.** Quality assurance/quality control for the GC-MS/MS analysis

Extraction efficiency, reproducibility, and accuracy were assessed using ¹³C-labeled surrogate standards, method blanks, and analysis of a standard reference material (SRM 1957, NIST). Limits of quantification (LOQs) were calculated as $LOQ = \overline{x_b} + k \times s_b$, where $\overline{x_b}$ indicates the mean of method blank results, *k* indicates the Students' *t*-value appropriate for the single-tailed 99th percentile *t* statistic and a standard deviation estimate with n-1 degree of freedom, and s_b indicates the sample standard deviation of the replicated method blank samples. The recovery rates of the surrogate standards ranged from 70±10 % to 97±9 %.

314

315 **2.2.6.** Statistical analysis of PCBs and PCB-participant trait relationships.

PCB congeners were assessed for detection frequency, defined as the percent of the 104 materal serum samples with PCB values over the LOQ, and labeled as detected (non-censored) or nondetected (censored) for each sample. Individual or co-eluting congeners that were detected in $\geq 50\%$ (n=52) of samples were selected for further analysis due to the increased robustness of statistical methods. PCBs 153+168, 170, 180+193, and 187 met this cutoff. All PCB congener values (ng) were then adjusted by maternal serum weight (g), and these serum weight-adjusted values were used in all remaining analyses. PCB analyses described in this section were

323 completed with the NADA R Package v1.6-1.1 using R v4.1.3, unless otherwise specified (Helsel,
 324 2005). NADA is optimized for censored environmental data (Lee, 2020)

325

326 Summary statistics (mean, median, standard deviation) were estimated for PCBs 153+168, 170, 327 180+193, and 187 using the censtats function, which reports statistics from three methods: 328 reverse Kaplan-Meier (a non-parametric test that does not assume a normal distribution of the 329 data), Robust Regression on Order Statistics (ROS; a semi-parametric model that assumes the 330 detected data is normally distributed but makes no assumptions about the censored data), and 331 Maximum Likelihood Estimation (MLE; a parametric model that assumes a normal distribution of 332 all data). The data were log-transformed for ROS and MLE to attain normality, due to the right-333 skew of the non-transformed data. All three models avoid removal, replacement, or imputation of 334 the nondetected values, instead estimating statistics using all data points.

335

336 PCBs 153+168, 170, 180+193, and 187 were correlated with one another using Kendall's tau for 337 left-censored data, a nonparametric correlation coefficient that measures the monotonic 338 association between two variables, one or both of which may include censored data. Both 339 detected and non-detected data were included in the correlations. MARBLES participant traits 340 (related to demographics, maternal health, birth factors, and child neurodevelopment) were 341 correlated with PCBs 153+168, 170, 180+193, and 187 values using Kendall's tau for left-342 censored data, and p-values were corrected by FDR. To assess which participant traits most 343 contributed to the levels of PCBs in the maternal serum, we computed fitted multiple linear 344 regression models. First, trait-PCB congener pairs were filtered to those that were associated with 345 a raw p-value < 0.2. If multiple trait-PCB congener pairs met this cut-off and the traits were 346 correlated with each other, r > 0.5, the trait-PCB pair with the less significant p-value was removed 347 from the analysis. This was done to remove multicollinearity and increase the reliability of the 348 model. With the remaining PCB-trait pairs, a fitted multiple linear regression equation for censored 349 data was computed using the cenmle function. We then assessed detection frequencies and 350 congener levels for all congeners across maternal age groups (>35 vs ≤35), offspring birth year 351 (2006-2011 vs 2012-2016), maternal BMI (>25 vs ≤25), offspring ASD diagnosis (ASD vs non-TD 352 vs TD), and offspring sex (male vs female) using coin R package v1.4.2, VGAM R package v1.1.6, 353 and censReg R package v0.5.34.

354

355 To further examine the relationship between maternal serum PCB levels and diagnosis of ASD in 356 the offspring, the Peto-Prentice non-parametric test was used to test the means of PCB values 357 between diagnostic groups (ASD/non-TD/TD). The Peto-Prentice test reports two-sided p-values 358 which were divided in two to produce one-sided *p*-values. To further examine the relationship 359 between maternal serum PCB levels and maternal pre-pregnancy BMI, we correlated PCB-BMI 360 tau with Kow, the octanol-water partition coefficient, for each PCB: 153+168, 170, 180+193, and 361 187 (Hawker & Connell, 1988). For co-eluting PCB congeners (PCBs 153+168 and 180+193), 362 we averaged the Kow of the two congeners.

363

364 **2.3. Placental DNA methylation analysis**

365

2.3.1. Whole genome bisulfite sequencing (WGBS)

The placental samples and WGBS data used in this study were previously described (Ladd-Acosta et al., 2021; Zhu et al., 2022). Briefly, 157 MARBLES and 47 EARLI placental samples were frozen within 4 hours of birth. DNA was extracted from the placental samples and treated with sodium bisulfite. Following whole genome sequencing of bisulfite-treated DNA, sequencing files were processed, aligned to the hg38 genome, and converted to CpG methylation count matrices.

374 **2.3.2.** Placental DNA co-methylation network analysis

375 We analyzed placental DNA methylation using Comethyl, v1.1.1 with R v 4.1.0, a published R 376 package that performs weighted gene correlation network analysis (WGCNA) for whole-genome 377 bisulfite sequencing (WGBS) data (Mordaunt et al., 2022). Comethyl forms modules from groups 378 of genomic regions that have correlated methylation, meaning that the proportion of CpGs that 379 are methylated in a given region correlate with the proportion of CpGs methylated in other regions 380 across samples. Modules are biologically informative because regions with correlated methylation 381 tend to be part of the same biological pathways and are less susceptible to random variations in 382 methylation than are individual CpG sites. In order to build modules from genomic regions that 383 are particularly informative, we filter regions to include only those that have variable methylation 384 across samples and therefore, may contribute to differential phenotypes. Methylation of a given 385 module is represented by a single value for each sample, called the "eigennode", where a more 386 positive eigennode value reflects higher methylation levels and a more negative value reflects 387 lower methylation.

388

389 Specifically, 157 individual placenta Bismark CpG reports were read into a single BSseq object 390 that was used to calculate the number of CpGs at different filtering options for both sequencing 391 coverage and number of samples. Ten samples were removed due to low sequencing coverage, 392 resulting in 147 samples being used for analysis. CpGs with at least 4x coverage in at least 80% 393 of the 147 samples were selected to form regions, resulting in 13,056,694 filtered CpGs (44% of 394 CpGs). Regions, defined as 3 or more CpGs separated by no more than 150 base pairs, were 395 filtered for those with at least 12x coverage and a methylation standard deviation of at least 5%, 396 resulting in 199,944 filtered regions. The methylation data was then adjusted for the top 26 397 principal components to adjust for potential confounding variables (Parsana et al., 2019). Using 398 the adjusted methylation data, scale-free topology with Pearson correlations was assessed to 399 evaluate fit and connectivity of the model. A soft power threshold of 15 was selected, meaning 400 that all correlations were raised to the power of 15 to increase the strength of strong correlations 401 and minimize weak correlations and background noise. Finally, modules were identified using a 402 two-phase clustering approach that reduces computational intensity: filtered regions were 403 grouped into 6 blocks using k-means clustering, then a full network analysis was performed for 404 each block. Modules were identified in each block through hierarchical clustering and adaptive 405 branch pruning, then were merged if their eigennode values were highly correlated (r > 0.9). 406 Eigennode values are a single value that summarizes the methylation of a module for each 407 sample. Regions not assigned to a module were assigned to the grey module. 408

409 **2.3.3. Co-methylation module, sample, and trait correlations**

410 Once modules were identified, we correlated module eigennode values with one another to 411 identify highly related pairs. Correlations were calculated by Bicor, and *p*-values were derived 412 based on Fisher's transformation.

413

We then correlated module eigennode values with MARBLES participant traits (related to demographics, maternal health, birth factors, and child neurodevelopment) as well as measured maternal serum PCB values. Module eigennode values were correlated with participant traits using Bicor, and with PCB values using Kendall's tau for left-censored data (NADA R package).

418

419 **2.3.4.** Co-methylation module annotation

420 Module regions were annotated to genes using the Genomic Regions Enrichment of Annotations 421 Tool (GREAT) and the hg38 genome (McLean et al., 2010). A region assigned to a module was 422 annotated to a gene if its genomic coordinates fell within the gene's regulatory domain, defined 423 as 5 kb upstream and 1 kb downstream from its transcription start site, or up to 1 Mb from the 424 transcription start site until the nearest gene's regulatory domain. Regions can map to zero, one,

10

425 or multiple genes. Gene information was provided by BioMart while gene context and CpG context 426 were provided by annotatr (Cavalcante & Sartor, 2017). Genic features include promoters (<1kb 427 upstream of a transcription start site), 5'UTRs, exons, introns, 3'UTRs, enhancers, intergenic 428 regions, and regions 1kb-5kb upstream of a transcription start site (Cavalcante & Sartor, 2017). 429 CpG features include CpG islands (regions of the genome with a high frequency of CpG sites as 430 defined by UCSC Golden Path), CpG shores (the 2kb upstream and downstream of CpG island 431 boundaries), CpG shelves (the 2kb upstream and downstream of CpG shores), and the open sea 432 (beyond 4kb from CpG island boundaries) (Cavalcante & Sartor, 2017).

433

We analyzed the overlap between module regions and partially methylated domains (PMDs) using placenta PMDs previously identified by a machine learning approach on the hg18 genome (Schroeder et al., 2013). We used the UCSC liftover tool to lift the hg18 PMDs to hg38, then compared regions assigned to modules to PMDs; a region was considered within a PMD if the entire region fit in the PMD.

439

440 **2.3.5. Co-methylation module preservation**

441 To assess the consistency of modules generated by the MARBLES samples we performed 442 module preservation using an independent dataset from the EARLI study. We called modules from 443 the EARLI dataset using CpGs and regions restricted to those covered in the MARBLES dataset. 444 Methylation data was corrected for the top 16 principal components, and a soft power threshold 445 of 23 was selected to achieve a high fit for the model. Pearson correlation was then used to 446 identify associations between regions and to call modules. We evaluated the MARBLES and 447 EARLI modules through multiple statistics, assessing the quality, preservation, separability, and 448 accuracy of each module (Langfelder et al., 2011). Module assignments are permuted 100 times 449 to calculate Z-scores and P-values. Based on simulation studies by Langfelder et al., 2011, we 450 considered Z-scores over 10 to be strong evidence for module preservation and Z-scores 451 between 2 and 10 to be weak-moderate evidence.

452

453 3. RESULTS and DISCUSSION

454

455 **3.1.** Highly chlorinated PCB congeners are most frequently detected in maternal serum

456 We measured levels of all 209 PCB congeners in 104 MARBLES study samples of maternal 457 serum collected at time of delivery (Figure 2A) (Supplemental Tables S1 and S2) (Hertz-458 Picciotto et al., 2018). While most human PCB studies use serum collected during pregnancy, 459 delivery serum provides a unique timepoint to study lipid-soluble PCBs because maternal plasma 460 free fatty acids have been found to double during labor (Kashyap et al., 1976). In 27 instances, 461 two-four PCB congeners co-eluted, resulting in 173 PCB measurements per sample. Each 462 sample had between zero and 41 PCB congeners detected, with a mean of 6.68 and a median of 463 4 congeners detected per sample. Eighty-one single or co-eluting PCB congeners were detected 464 in zero samples; 76 in 1-10% of samples; 5 in 11-20% of samples; 7 in 21-50% of samples; and 465 4 in ≥50% of samples (Supplemental Table S1). These detection frequencies are lower than 466 those in postmortem human brain using similar methods (Li, Hefti, et al., 2022). In both studies, 467 highly chlorinated PCBs were more likely to be detected than lower chlorinated PCBs, despite the 468 decreased response of the instrument as the degree of chlorination increases. This may be 469 explained by highly chlorinated PCB congeners' resistance to metabolization, leading to 470 bioaccumulation in the body (Kato et al., 1980; Mathews & Anderson, 1975; Mills et al., 1985).

471
472 The four PCB congeners/congener pairs that were detected in ≥50% (n=52) of samples were
473 selected for further analysis due to the increased robustness of statistical methods when censored
474 data points represent less than half the data: PCBs 153s + 168, 170, 180 + 193, and 187. These
475 PCB congeners were also detected in ≥50% of postmortem brain samples (Li, Hefti, et al., 2022)

and found at high concentrations in maternal blood plasma, cord blood plasma, breast milk
(Guvenius et al., 2003), and placenta (Naqvi et al., 2018). No PCB congeners were detected in
fewer than 50% of all samples but in greater than 50% of one of the ASD diagnostic groups
(ASD/non-TD/TD), indicating that we did not miss a congener that may discriminate between
diagnostic groups.

481

482 3.2. Highly detected PCB congeners (153 + 168, 170, 180 + 193, and 187) have variable but 483 correlated levels in maternal serum

484 We estimated summary statistics (mean, median, standard deviation) for PCBs 153 + 168, 170, 485 180 + 193, and 187 (Table 1 and Supplemental Table S3) using both the detected and non-486 detected data in the models, which has been shown to be more effective than substituting or 487 replacing non-detected data points (Ahmadi et al., 2021; Canales et al., 2018). Inputted PCB 488 values were adjusted by serum weight, which did not differ significantly across ASD diagnostic 489 groups (ASD/non-TD/TD) (Supplemental Figure S4). PCBs 153 + 168 and 180 + 193 had higher 490 median and mean concentrations than PCBs 170 or 187. PCB 153 and PCB 180 have previously 491 been detected as among the 12 most abundant PCB congeners in maternal serum in the 492 MARBLES cohort (Sethi et al., 2019), as well as highly detected in brain tissue (Chu et al., 2003; 493 Corrigan et al., 1998; Dewailly et al., 1999; Li, Hefti, et al., 2022; Mitchell et al., 2012). Additionally, 494 PCB 153 + 168 are the least lipophilic of this group, meaning they are more readily released from 495 adipose tissue into the blood, potentially resulting in higher average serum levels (Louis et al., 496 2016).

497

498 Table 1. Estimated summary statistics for PCB congeners in maternal serum by 499 Regression on Order Statistics

DCB Congonor	DOD Converses Detected ($n 0$) Medice ($n n/n$) Mean ($n n/n$) CD ($n n/n$)											
PCB Congener	Detected (n,%)	Median (ng/g)	Mean (ng/g)	ວມ (ng/g)								
PCB 153 + 168	54 (51.9)	0.0283	0.0368	0.0301								
PCB 170	53 (51.0)	0.0069	0.0114	0.0091								
PCB 180 + 193	80 (76.9)	0.0192	0.0272	0.0240								
PCB 187	56 (53.8)	0.0078	0.0104	0.0086								

500

501 We next tested the hypothesis that measured values of PCB congeners in serum correlate with 502 one another. Confirming previous findings (DeVoto et al., 1997; Pauwels et al., 1999), PCBs 153 503 + 168, 170, 180 + 193, and 187 were all significantly correlated (tau correlation coefficients ranged 504 from 0.48 to 0.63, with all *p*-values < 10^{-12}), though correlation coefficients were lower than in 505 previous studies, likely due to our inclusion of non-detected data points (Figure 2B) 506 (Supplemental Table S4).

507

508 **3.3.** Participant traits related to demographics, maternal health, birth factors, and child 509 neurodevelopment are correlated

510 Next, we took advantage of the large volume of metadata collected within the MARBLES study to 511 explore relationships between traits related to demographics, maternal health, birth factors, and 512 child neurodevelopment (Supplemental Tables S5 and S6). To identify linear and monotonic 513 relationships, we correlated all numerically-coded participant traits using Pearson (linear) (Figure 514 3A) (Supplemental Tables S7, S9) and Spearman (monotonic) (Supplemental Figure S2) 515 (Supplemental Tables S8, S10) correlations. Spearman detected 54 significant trait-trait 516 correlations (FDR < 0.05), two of which were not detected by Pearson, while Pearson detected</p>

It is made available under a CC-BY-NC 4.0 International license .

13

518 55, three of which were not detected by Spearman, indicating the value of performing both 519 methods. Unsurprisingly, traits within a given category were often strongly correlated, including 520 demographic traits of parental ages, parental education levels, home ownership, and delivery 521 payer (public or private insurance), as well as paired demographic traits of the two parents such 522 as birthplace, race, ethnicity, age, and education. Birth factors, including birth weight and birth 523 length, as well as maternal health factors, including omega 3 and plasma PUFA levels, were also 524 strongly correlated (FDR < 0.05).

525

526 ASD diagnosis strongly correlated with ADOS comparison score (FDR = 0) and Mullen score 527 (FDR = 0), which are both used to diagnose ASD, as well as birth year (FDR < 0.01), with rates 528 of diagnosis increasing from 2006 to 2016. This aligns with previous findings that ASD is 529 increasing in prevalence and/or diagnostic rates (CDC, 2022). ADOS comparison score 530 correlated (FDR < 0.05) with prenatal vitamin use, which has previously been shown to be 531 protective for ASD (Levine et al., 2018; Schmidt et al., 2011, 2019). To further examine this 532 relationship in our cohort, we used chi-squared to test if prenatal vitamin use in month 1 of 533 pregnancy (yes/no) was significantly different for ASD diagnostic groups (TD/non-TD/ASD). 534 Aligning with previous findings, prenatal vitamin use was associated with ASD diagnosis in the 535 protective direction (P = 0.0062) (Supplemental Figure S3). Additionally, Mullen Score was 536 significantly associated with mom education (FDR = 0.02), with greater educational attainment as 537 child Mullen Score increased. Higher Mullen scores indicate greater cognitive development and 538 decreased likelihood of ASD diagnosis (Supplementary Figure S4). Low maternal education has 539 been associated with increased risk and severity of ASD in previous studies (Dong et al., 2022; 540 Leonard et al., 2005; Schoultz et al., 2010).

541

542 **3.4.** PCB levels in maternal serum are correlated with participant traits, particularly 543 maternal age, but not child ASD diagnosis

544 Next, we explored associations between participant traits and levels of PCBs 153 + 168, 170, 180 545 + 193, and 187 in maternal serum collected at delivery (Figure 3B). Based on existing literature, 546 we hypothesized that maternal serum PCB levels would be positively associated with diagnosis 547 of ASD in the offspring (Bernardo et al., 2019; Lyall, Croen, Sjödin, et al., 2017), negatively 548 associated with maternal BMI (Koh et al., 2016; Lan et al., 2021; Mullerova et al., 2008), and 549 negatively associated with child birth year (year of maternal serum sample collection), with the 550 latter prediction reflecting data indicating that environmental levels of highly chlorinated PCBs, 551 including PCBs 153 + 168, 170, 180 + 193, and 187, are decreasing over time (Brändli et al., 552 2007; Jones et al., 1992).

553

554 Kendall's tau for left-censored data was estimated for each PCB-trait pair, and p-values were 555 adjusted by FDR (Supplemental Table S11, S12, S13). PCBs 153 + 168, 170, 180 + 193, and 556 187 were not significantly (FDR < 0.05) associated with ASD diagnosis, which we confirmed by 557 the Peto-Prentice test (Supplemental Table S14). At FDR < 0.05, PCBs 153+168 and 187 were 558 significantly associated with maternal and paternal ages, paternal education level, and home 559 ownership (renter/owner); PCB 170 with maternal and paternal ages; and PCB 180+193 with 560 maternal and paternal ages and education levels (Supplemental Figure S5). Because the 561 demographic variables of maternal and paternal age and education, home ownership, and 562 delivery payer are all highly correlated with one another (Figure 3A), it was difficult to identify 563 which traits were the most significant predictors of PCB levels in maternal serum.

564

565 To address this question, we computed fitted multiple linear regression models for censored data. 566 First, we identified all PCB-trait correlations with FDR < 0.2. This cut-off was purposely lenient to 567 include all traits that may be important in affecting PCB levels. To address multicollinearity, we 568 removed a PCB-trait pair from analysis if the trait was highly correlated with another trait (r > 0.5)

569 that was more strongly associated (lower FDR) with the PCB congener. With all PCB-trait pairs 570 that met these cut-offs, we performed multiple linear regression using a log scale to normalize the 571 left-censored PCB data. Though all congeners' multiple linear regression models shared 572 characteristics, each was distinct despite the high correlation between all four PCB 573 congeners/congener pairs (Figure 2B). Maternal age (MomAge) was the most significant 574 predictor (P < 0.00001) of maternal levels of PCBs 153 + 168, 170, 180 + 193, and 187, with 575 increasing age predicting increasing serum PCB levels. PCBs 153 + 168 (P < 0.05) and 180 +576 193 (P < 0.005) were also strongly predicted by the child's birth year (year of maternal serum 577 sample collection), with decreasing levels of PCBs from 2006 to 2016. Higher maternal serum 578 levels of PCB 153 + 168 was also predicted by lower maternal BMI (P < 0.05), while higher 579 maternal serum levels of PCB 180 + 193 were predicted by higher levels of maternal plasma 580 polyunsaturated fatty acids (P < 0.05) (Figure 3B). Standard errors of the coefficients and other 581 regression model variables are reported in Supplemental Table S14. 582

- 583 Fitted multiple linear regression models:
- 584 585

586

587 588 InPCB 153 + 168 = 211 + 0.134*MomAge - 0.0322*MaternalBMI - 0.109*BirthYear^a

InPCB 170 = -8.9024 + 0.1127*MomAge

- InPCB 180 + 193 = 219.31014 + 0.09813*MomAge + 0.00588*MaternalPlasmaPUFA 0.11286*BirthYear^a
- 590 591 592

593

594

589

• InPCB 187 = -10.1156 + 0.12414*MomAge

^aBirth year refers to child birth year which is also the year of maternal serum sample collection

595 The multiple linear regression models partially confirmed our hypotheses that child diagnosis of 596 ASD, year of sample collection, and maternal BMI would be significant predictors of maternal 597 serum PCB levels. PCBs 153 + 168, 170, 180 + 193, and 187 were not significantly predicted by 598 ASD diagnosis or ADOS score, which we confirmed by the Peto-Prentice test (Supplemental 599 Table S15). However, the negative associations between PCB levels and year of sample 600 collection as well as maternal BMI confirmed our hypotheses and aligned with previous 601 publications. Due to the negative association between BMI and PCBs, we decided to not lipid-602 adjust our PCB values. Previous studies have indicated a potential causal effect of PCBs on 603 serum lipid levels (Hennig et al., 2005; Langer et al., 2003), and have found lipid standardization 604 to be prone to bias (Schisterman et al., 2005). Further, different groups of PCBs are differently 605 associated with total serum lipids, making lipid adjustment difficult for all 209 PCB congeners in 606 our study (Aminov et al., 2013).

607

608 To investigate why PCB 153 + 168 was more strongly negatively correlated with (and predicted 609 by) maternal BMI than the other three PCB congeners/congener pairs we correlated the BMI-PCB 610 tau value with the octanol-water partition coefficients (Kow) for each PCB congener/pair (Supplemental Figure S6) (Supplemental Table S16). Kow represents the lipophilicity of a 611 612 compound, with more positive values representing increased lipophilicity and decreased water-613 solubility. Of the four PCB congeners/congeners pairs, PCB 153 + 168 is the least lipophilic 614 (lowest K_{ow}) and has the strongest negative PCB-BMI correlation tau value. This inverse 615 relationship between BMI and serum levels of PCBs with lower lipophilicity is revealed among 616 individuals with lower fat stores (lower BMI) that have higher amounts of PCB 153 + 168 in their bloodstream. This may occur with PCB 153 +168 more than the other congeners because its 617 618 lower lipophilicity, meaning PCB 153 +168 has lower propensity to stay in the fat stores and 619 greater solubility in the bloodstream (Bruno et al., 2021).

15

female). The dotted line indicates the value of log $p \ge (-1)$ of Bonferroni-adjusted multiple comparisons ($p = 2.89 \ge 10^{-4}$) (Li et al., 2022). Detection frequencies were determined in 104 serum samples for 209 PCB congeners, analyzed as 173 peaks of single or co-eluting congeners. Red dots in panels (C1 and C2) indicate PCB congeners with a significant difference. PCB congeners are plotted on the x-axis in the order of their Ballschmiter and Zell number, as defined by the EPA (US EPA, 2015). Congeners with p = 1 were not plotted. The p values of the corresponding PCB congeners are presented in Table S17.

It is made available under a CC-BY-NC 4.0 International license .

16

Lastly, the multiple linear regression models showed that PCB 180 + 193 serum levels are predicted by maternal plasma polyunsaturated fatty acid levels. PCBs have previously been associated with polyunsaturated fatty acids in human serum due to the high prevalence of both PCBs and PUFAs in fish and fish oil (Ashley et al., 2013; Bourdon et al., 2010; Dellinger et al., 2018; Ge et al., 2019; Tøttenborg et al., 2015). However, we did not include dietary information in this study, so cannot validate a hypothesis for the association between PCB 180 + 193 and dietary polyunsaturated fatty acid intake.

628

629 Based on our findings with participant traits and PCBs 153 + 168, 170, 180 + 193, and 187, we 630 assessed detection frequencies (Figure 3C) and levels (Supplemental Figure S7) of all PCB 631 congeners by offspring sex, offspring ASD diagnosis, maternal age, maternal BMI pre-pregnancy. 632 and offspring birth year (year of maternal serum sample collection) (Supplemental Table S17). 633 Overall, 18 congeners were more frequently detected in women who gave birth at over age 35 634 (and therefore had their serum collected at over age 35) than those who gave birth at age 35 or 635 younger. One congener was more frequently detected in women with pre-pregnancy BMI 25 or 636 under (PCB 169), while one congener was more frequently detected in women with TD offspring 637 compared to ASD/non-TD (PCB 194). Seven congeners were more frequently detected in those 638 with sample collection (child birth year) between 2006-2011 compared to 2012-2016.

639

640 **3.5.** Placental DNA co-methylation modules map to large blocks of adjacent regions

641 We next assessed DNA methylation patterns from placental samples in the MARBLES cohort to 642 analyze the relationships between DNA methylation, maternal serum PCB levels, and participant 643 traits including those related to child neurodevelopment. Although we did not see a significant 644 association between maternal serum PCB levels and child ASD diagnosis at the population level, 645 placental DNA methylation may act as a measurable intermediary at the level of the individual. 646 To identify patterns of DNA methylation, we used the Comethyl R package (Mordaunt et al., 2022), 647 which performs weighted gene correlation network analysis (WGCNA) with WGBS data. This 648 method allowed us to look at modules of co-methylated regions instead of individual CpG sites. 649 which are more susceptible to stochastic variation. Additionally, Comethyl module eigennodes 650 can be correlated with any number of traits of interest, using a statistical method of choice.

651

652 CpGs from 157 placental samples were grouped into regions from which modules were 653 constructed. Correlations between region methylation were all raised to the power of 15 to amplify 654 strong connections and decrease the background noise of weak connections (Figure 4A). Regions formed 6 blocks (Supplemental Figure S15) from which 27 modules were identified. 655 656 plus a grey module, to which regions not assigned to another module were assigned. From 657 199,945 total filtered regions, 928 were assigned to a module (0.46%) while the remaining regions 658 (99.54%) were assigned to the grey module. Each of the 27 modules contained between 10 and 659 89 regions (Figure 4B), which is consistent with previous Comethyl findings using cord blood samples (Mordaunt et al., 2022). However, the modules generated from placenta were unique 660 661 because most modules mapped to large blocks of adjacent regions (Figure 4C) (Supplemental 662 **Table S23).** This is in contrast to other tissues, where modules typically map to short regions 663 across several chromosomes (Mordaunt et al., 2022). This unique finding led us to investigate 664 where the modules mapped on the genome.

It is made available under a CC-BY-NC 4.0 International license .

3.6. Placental DNA co-methylation modules annotate to gene introns and CpG open sea
 contexts

668 We tested the hypothesis that co-methylated modules mapped to partially methylated domains

669 (PMDs), regions of the placental genome with reduced average methylation levels (approximately

- 670 40-45% methylated) that are highly variable across individuals (Schroeder et al., 2013). Because 671 we selected for regions with a high standard deviation in methylation levels and found that filtered
- regions with the highest standard deviations had 40-60% mean methylation (Supplemental

18

673 Figure S13), we hypothesized that these regions would preferentially map to PMDs (Schroeder 674 et al., 2013). Of the 928 regions assigned to modules (excluding the grey module), 407 (43.86%) 675 mapped to PMDs (Supplemental Table S23). PMDs cover an average of 37% of the placental 676 genome (Schroeder et al., 2013), showing that PMDs are over-represented in modules compared to the placental genome (chi-squared P < 0.0001) (Supplemental Table S24). Of the 27 modules, 677 678 11 consist of 100% regions that map onto PMDs; 9 consist of 100% regions that fall outside of 679 PMDs; and 7 consist of a mixture. The average mean methylation across the regions that do not 680 map to PMDs is 0.6628 (SD 0.1142), while the average mean methylation across the regions that 681 do map to PMDs is 0.6262 (SD 0.1124). These relatively high standard deviations indicate the 682 high variability in methylation levels across regions in both PMDs and non-PMDs.

683

684 We then annotated regions within modules to genes, and identified regions' genic features (i.e. 685 promoter, exon, intron, UTR, enhancer, intergenic) and CpG features (i.e. island, shore, shelf, open sea) (Supplemental Table S23). We found that 877/928 (94.5%) of regions within modules 686 687 mapped to open sea CpG contexts, supporting previous findings that most DMRs do not reside 688 at CpG islands (Visone et al., 2019). 700/928 (75.4%) of regions in modules mapped to introns 689 of genes, while only 116,878/199,944 (58.5%) of total filtered regions mapped to introns. This 690 indicates that introns are over-represented amongst regions that co-methylate in placenta, 691 compared to background regions (chi-squared P < 0.0001) (Supplemental Table S24). The 692 enrichment for introns is likely related to the finding that the entire gene body, including introns 693 and exons, is more highly methylated over active genes in placenta (Schroeder et al, 2016), and 694 introns cover a larger genomic territory than exons.

695

696 We also correlated module eigennodes with one another to identify highly similar modules and 697 explore whether they annotated to the same or different genes (Figure 4D) (Supplemental 698 Figure S16). The most highly correlated pairs of modules were DarkTurquoise with LightCyan 699 (Bicor = 0.792, *p*-value = 6.08E-33) and Red with DarkRed (Bicor = 0.718, *p*-value = 1.44E-24). 700 Though these modules are strongly correlated, they were not combined into a single module 701 because they did not meet the Bicor cut-off of 0.9. The DarkTurguoise and LightCyan modules 702 consist of large blocks of adjacent regions that map to CSMD1, a gene that codes for a 703 complement control protein. Nearly all of CSMD1 lies within a placental PMD (Schroeder et al., 704 2013). Regions in both modules map primarily to CSMD1 introns with one region from each 705 module mapping to one of CSDM1's 69 exons. The Red and DarkRed modules both consist of 706 large blocks of adjacent regions that map to AUTS2, activator of transcription and developmental 707 regulator. The DarkRed and Red regions lie approximately 396-526kb and 364kb-1Mb upstream 708 of AUTS2, respectively, showing that regions from the two modules overlap with one another on 709 the genome. Overall, these results highlight the complexity of DNA co-methylation in the placental 710 genome.

711

3.7. Placental DNA co-methylation modules are correlated with child neurodevelopment and map to genes previously associated with ASD, including *GALC, AUTS2,* and *CSMD1*

714 explore potential relationships between placental DNA methylation and child То 715 neurodevelopment, we correlated module eigennodes with participant traits using Bicor (Figure 716 5A). We also mapped regions within modules to genes in order to relate methylation in certain 717 genes to traits of interest (Figure 5C). Four modules significantly (P < 0.05) correlated with a child 718 neurodevelopmental trait (ASD diagnosis, Mullen Score, or ADOS comparison score): Salmon, 719 DarkRed, Red, and DarkTurquoise (Figure 6 and Supplemental Figures S17-S19). These 720 modules mapped, respectively, to GALC, AUTS2, AUTS2, and CSMD1, all of which have 721 previously been associated with ASD (Cukier et al., 2014; Hori et al., 2021, p. 2; Zhu et al., 2022). 722

It is made available under a CC-BY-NC 4.0 International license .

20

724 The GALC Salmon module negatively correlated with ASD diagnosis (P < 0.01), as well as ADOS 725 comparison score (P < 0.05), but positively correlated with Mullen Score (P < 0.05). The Salmon 726 module also positively correlated with maternal education (P < 0.05), indicating that increased 727 placental DNA methylation at Salmon loci (GALC gene) correlates with more typical development 728 (and less ASD diagnosis) in the offspring and higher maternal education levels. This also fits with 729 the positive correlation of maternal education with the Mullen Score, for which higher values 730 reflect improved cognition and lower ASD diagnosis (Figure 5A). The Salmon module regions 731 map to GALC, a gene that encodes the enzyme galactosylceramidase, a component of myelin, 732 the protective coating around some nerve cells. These regions were previously identified as 733 placenta ASD hypomethylated DMRs in the MARBLES cohort using a DMR bioinformatic 734 approach (Zhu et al., 2022).

735

736 The AUTS2 Red and DarkRed modules correlated negatively with Mullen Score, indicating higher 737 methylation at AUTS2, a known ASD risk gene, when Mullen Scores are lower and ASD is more 738 likely to be diagnosed. This study may be underpowered to detect a significant correlation 739 between these modules and ASD diagnosis (Red P = 0.219, DarkRed P = 0.243), a categorical 740 variable (ASD, non-TD, TD), despite their significance with Mullen Score, a continuous variable. 741 Additionally, the correlation with Mullen Score but not with ADOS Score may reflect that 742 methylation at this loci is associated with cognitive measures, as reflected by Mullen, but not with 743 social aspects of ASD, as reflected by ADOS. The AUTS2 DarkRed module also correlated 744 negatively with maternal omega 3s, while the Red module correlated negatively with prenatal 745 vitamin use, suggesting that high omega 3s and taking prenatal vitamins are associated with lower 746 DNA methylation at this locus, in the expected protective direction for cognition.

747

748 The CSMD1 DarkTurguoise module negatively associated with both ADOS comparison score (P 749 < 0.05) and maternal chronic hypertension (P < 0.005) (Figure 6A-B). Again, a significant 750 correlation was not detected with ASD diagnosis (P = 0.080), potentially because it is a categorical 751 variable, or with Mullen Score, perhaps reflecting the sensitivity of CSMD1 methylation to the 752 social aspects of ASD that are measured by ADOS rather than the cognitive aspects that are 753 measured by Mullen. Hypertensive disorders during pregnancy have been shown to potentially 754 increase risk of ASD in offspring (Curran et al., 2018) and common variants in CSMD1 have 755 previously been associated with both hypertension (Hong et al., 2010) and ASD (Cukier et al., 756 2014), as well as schizophrenia (Liu et al., 2017; Ripke et al., 2014). CSMD1 has high expression 757 in brain, particularly in neurons (Baum et al., 2020), and was identified as a hypermethylated 758 differentially methylated gene in brain tissue from individuals with Dup15g (Dunaway et al., 2016), 759 a common CNV observed in ASD (Chaste et al., 2014; Hogart et al., 2010).

760

761 **3.8.** Placental DNA co-methylation modules are correlated with maternal serum PCBs

762 To investigate relationships between maternal serum PCBs and placenta DNA methylation, we 763 correlated module eigennodes with PCBs 153 + 168, 170, 180 + 193, and 187 using Kendall's 764 tau for left-censored data (Figure 5B). The CSMD1 DarkTurguoise module negatively correlated 765 (P < 0.05) with PCBs 153+168, 180+193, and 187 (Figure 6C-F); the AUTS2 Red (P < 0.05) and 766 ADGRD1 Tan (P < 0.05) modules significantly negatively correlated with PCB 187; the SOX11 767 DarkGreen module significantly negatively correlated with PCB 170 (P < 0.05); and the RoyalBlue 768 module significantly positively correlated with PCB 153 + 168 (P < 0.05). Of the seven significant 769 module - PCB correlations, six were negative correlations, meaning that individuals with higher 770 serum PCB levels had lower methylation levels at those loci. These findings align with a mouse 771 model of gestational PCB exposure, in which placenta displayed global hypomethylation in both 772 sexes as well as a large skew in DMRs, where 81% of female and 85% of male DMRs were 773 hypomethylated in PCB-exposed mice compared to controls (Laufer et al., 2022).

776 Interestingly, the CSMD1 DarkTurguoise and AUTS2 Red modules correlated with maternal 777 PCBs as well as measurements of child neurodevelopment. In both modules, the methylation 778 change associated with elevated maternal serum PCB levels appears to be in the opposite 779 direction as ASD in the child, which is the inverse of our hypothesis but accompanies our finding 780 that ASD diagnosis was non-significantly negatively correlated with PCBs 153+168, 170, 781 180+193, and 187 (Figure 3B). A previous study using a mouse model of prenatal PCB exposure 782 identified DMRs that mapped to CSMD1 as well as AUTS2 in male and female placentas and 783 fetal brains (Figure 5C) (Laufer et al., 2022). Several DMRs mapped to each gene for both sexes 784 and tissues and were inconsistent in the direction of differential methylation, indicating that PCB 785 exposure may dysregulate DNA methylation at CSMD1 and AUTS2 in variable ways. Additionally, 786 methylation levels of CSMD1 in sperm have been inversely correlated with serum DDE levels in 787 Faroese individuals who are exposed to high levels of organic pollutants (Maggio et al., 2021). 788 DDE and PCB exposures often occur together, and both chemicals contain phenyl groups and 789 chlorine molecules, indicating a potential convergent mechanism.

790

Additionally, it is notable that the *CSMD1* DarkTurquoise module correlated with maternal chronic hypertension and serum PCB levels **(Figure 6 B-F)**. Hypertension has previously been associated with PCBs, though correlations in the positive (Raffetti et al., 2020) and the negative (Warembourg et al., 2019) direction have both been found. Increases in systolic and diastolic blood pressure have also been previously associated with high fish intake during pregnancy (Warembourg et al., 2019), which is known to increase exposure to PCBs.

3.9. Placental DNA co-methylation modules are highly preserved in an independent dataset
 Lastly, we assessed the placental DNA methylation module quality and preservation in an
 independent WGBS ASD and TD placenta dataset from the EARLI study (Langfelder et al., 2011).
 EARLI networks were constructed using the same set of CpGs and regions as were used in the
 MARBLES dataset. The four types of features assessed were quality, preservation, accuracy,
 and separability.

804

All 27 modules had strong evidence for quality and preservation as shown by all modules having summary.qual and summary.pres Z-scores > 10. 19 modules had strong evidence for accuracy, including two of our modules of interest (*CSMD1* DarkTurquoise and *GALC* Salmon). In contrast, only eight modules showed evidence of separability in the reference set (MARBLES) and one module in the test set (EARLI), which did not include our modules of interest. These results suggest that the identified modules are of high quality and are consistent between multiple placenta datasets (Supplemental Figure S20)(Supplemental Table S25).

813 **4. CONCLUSIONS**

814

812

815 We measured all PCB congeners in maternal serum collected at delivery from an ASD enriched 816 risk cohort and detected 4 congeners/congener pairs (PCBs 153 + 168, 170, 180 + 193, 187) in 817 more than 50% of samples. While we found maternal age, year of sample collection, pre-818 pregnancy BMI, and polyunsaturated fatty acid levels to be predictive of maternal serum PCB 819 levels, we did not find an association between maternal PCBs and child ASD diagnosis. This 820 finding may be explained by the fact that PCB congener profiles in pregnant people are changing 821 over time and congeners that affect neuroevelopment may be less prevalent in our population 822 than those in previous studies. Additionally, PCBs may not alter neurodevelopment themselves, 823 but instead modify genetic risk through epigenetic marks such as DNA methylation.

824

To investigate this potential gene by environment interaction, we used a systems approach to identify regions with correlated DNA methylation in placenta. We identified and replicated 27 co-

827 methylated modules, 4 of which correlated with child neurodevelopment measurements (ASD 828 diagnosis, ADOS comparison score, or Mullen score), and 5 of which correlated with PCB 829 congener levels, as well as other variables, including maternal hypertension and prenatal vitamin 830 use. DNA co-methylation patterns in the placenta identified 2 gene loci (CSMD1 and AUTS2) that 831 were correlated with one or more PCB congeners and child neurodevelopment measures. 832 Interestingly, increased methylation at CSMD1 and AUTS2 correlated with higher rates of ASD 833 diagnosis but lower maternal serum PCB levels, indicating complex dysregulation at these loci 834 during development and the need for further investigation to clarify exact mechanisms. Together, 835 these results demonstrate the utility of comparing placental methylation patterns with multiple 836 variables to understand complex gene by environmental interactions in the etiology of ASD and 837 other neurodevelopmental disorders.

838

839 USE OF HUMAN SUBJECTS DECLARATION

This study was performed in accordance with the ethical principles for medical research involving human subjects in the Declaration of Helsinki. The University of California, Davis Institutional Review Board and the State of California Committee for the Protection of Human Subjects approved this study and the MARBLES Study protocols (IRB# 225645). Human Subjects Institutional Review Boards at each of the four sites in the EARLI Study approved this study and the EARLI Study protocols (IRB# 214753). Neither data nor specimens were collected until written informed consent to participate was obtained from the parents.
