Contributorship

MERS, FS, WT, and NV collected data, reviewed source manuscripts, and helped analyze data. MS, FS and SA contributed to the creation of online resources. OF and RJS performed statistical analyses. RT, NWM and SJM contributed to the planning, organization, and funding of the study. ES conceptualized and organized the study, performed data analyses, funded the study, and takes responsibility for the integrity of the work as a whole. All authors contributed to the writing and critical revision of the manuscript. The corresponding author attests that all listed authors meet authorship criteria and that no others meeting the criteria have been omitted.

Acknowledgements

We thank Ms Natalie Doughty, Mr Chris Davies, Dr Benjamin Dunmore, and Mr Nikita Zubkov who provided general public and patient input into accessibility of data, website, and software.

Many thanks also to all root study authors, patients and essential workers who have selflessly shared their time and data.

Copyright for publication

The Corresponding Author has the right to grant on behalf of all authors and does grant on behalf of all authors, a worldwide licence to the Publishers and its licensees in perpetuity, in all forms, formats and media (whether known now or created in the future), to (i) publish, reproduce, distribute, display and store the Contribution, (ii) translate the Contribution into other languages, create adaptations, reprints, include within collections and create summaries, extracts and/or, abstracts of the Contribution, (iii) create any other derivative work(s) based on the Contribution, (iv) to exploit all subsidiary rights in the Contribution, (v) the inclusion of electronic links from the Contribution to third party material where-ever it may be located; and, (vi) licence any third party to do any or all of the above.

Disclosures

All authors have completed the ICMJE uniform disclosure form at <http://www.icmje.org/disclosure-of-interest/> and declare: no support from any commercial organisation for the submitted work; no financial relationships with any organisations that might have an interest in the submitted work in the previous three years; no other relationships or activities that could appear to have influenced the submitted work.

Ethics approval

Ethical approval was obtained from the National Health System (UK) Health Research Authority via the Integrated Research Application System (reference 281880) for analysis of the Cambridge (UK) data. All the other data has been published and is in the public domain.

Funding

ES and MS are supported by the UK Medical Research Council (MR/R008051/1); the British Medical Association (the Josephine Lansdell Award); and the Association of Physicians of Great Britain and Ireland (Young Investigator Award to ES); the Wellcome Trust ISSF and the Cambridge BHF Centre of Research Excellence (RE/18/1/34212). MES and WT are full-time NHS physicians who have volunteered their time for this work. FS received in-kind funding by the AWS Diagnostic Development Initiative and Google TPU Research Cloud. NV is supported by a BLF-Papworth Fellowship from the British Lung Foundation and the Victor Dahdaleh Foundation (VPDCF17-18). AART is supported by a British Heart Foundation Intermediate Clinical Fellowship (FS/18/13/33281). OF is funded by the StatScale programme (EP/N031938/1). RJS is supported by Engineering and Physical Sciences Research Council grants EP/P031447/1 and EP/N031938/1, as well as ERC Advanced Grant 101019498. SA and SJM are funded by the British Lung Foundation (VPDCF17-18), the Medical Research Council, UK (MR/V028669/1), the NIHR Cambridge Biomedical Campus (BRC-1215-20014) and the Royal Papworth NHS Trust. NWM is supported by the British Heart Foundation (SP/12/12/29836), the Cambridge BHF Centre of Research Excellence (RE/18/1/34212), the UK Medical Research Council (MR/K020919/1), the Dinosaur Trust, BHF Programme grants to NWM (RG/13/4/30107), and the NIHR Cambridge Biomedical Research Centre.

The funders did not have a role in the study design, data collection or analyses or the decision to submit for publication.

Summary box

What is already known on this topic

Biomarkers such as CRP, D-dimer, and interleukin-6 have been proven to have prognostic value in SARS-CoV-2. However prognostic scores using these as building blocks have performed unevenly in different locations.

What this study adds

Commonly used biomarkers for SARS-CoV-2 have different efficacies in different parts of the world. For example, admission CRP and interleukin-6 levels are good prognostic markers for mortality in Asian countries but only average in Europe and North America. Prognostic markers and scores cannot be 'transplanted' from one region to another. This has implications not just for SARS-CoV-2 but also for scores in other conditions. We note a significant lag from the pandemic advent to data availability and this has no doubt impacted on patient care.

How this study might affect research, practice, or policy

Biomarkers and by extension prognostic scores should be validated in their target country/population before use. The infrastructure for data collection and analysis should be put in place so that this process can happen rapidly (ideally in an automated manner), in case of another pandemic.

ABSTRACT

Rationale: Sophisticated prognostic scores have been proposed for SARS-CoV-2 but do not always perform consistently. We conducted these meta-analyses to uncover why and to investigate the impact of vaccination and variants.

Methods: We searched the PubMed database for the keywords 'SARS-CoV-2' with 'biomarker' and 'mortality'. All studies published from 01/12/2020 to 31/03/2023 were surveyed. To aggregate the data, the *meta* library in R was used, and a random effects model fitted to obtain pooled AUCs and 95% confidence intervals for the European/North American, Asian, and overall datasets.

Results: Biomarker effectiveness varies significantly in different continents. Admission CRP levels are a good prognostic marker for mortality in Asian countries, with a pooled area under curve (AUC) of 0.83 (95%CI 0.80-0.85), but only an average predictor of mortality in Europe/North America, with a pooled AUC of 0.67 (95%CI 0.63-0.71, $P < 0.0001$). We observed the same pattern for D-dimer and IL-6. This variability explains why the proposed prognostic scores did not perform evenly. Notably, urea and troponin had pooled AUCs ≥ 0.78 regardless of location, implying that end-organ damage at presentation is a key prognostic factor. Very little data is available for vaccinated and variant cohorts but it appears that inflammatory biomarkers are performing less well. We note a significant lag from the pandemic advent to data availability and this has no doubt impacted on patient care.

Conclusions: Biomarker efficacies vary considerably by region. It is imperative that the infrastructure for collecting clinical data should be put in place ahead of a future pandemic.

Introduction

SARS-CoV-2 is a novel beta coronavirus of zoonotic origin first identified in Wuhan, China at the end of 2019, which led to the introduction of a Public Health Emergency of International Concern between February 2020 and May 2023. SARS-CoV-2 differs from previous viral threats in showing marked transmissibility during the asymptomatic/very early symptomatic stage¹ and person-to-person transmission by both airborne and fomite routes². At the beginning of the pandemic, there was no previous immunity, no known effective antiviral treatment, and no vaccine, resulting in a global death toll of over six million (<https://covid19.who.int/>).

Due to the overwhelming number of cases and the significant morbidity and mortality associated with SARS-CoV-2, reliable prognostic scores are critically important to maximize survivorship and optimize the use of limited resources. Sophisticated scoring systems have been proposed but have not performed consistently³⁻⁶. For example, El-Solh³ tested 4 prognostic models constructed to predict in-hospital mortality for SARS-CoV-2 patients; proposed by Chen *et al*⁷, Shang *et al*⁸, Yu *et al*⁹, and Wang *et al*¹⁰. All models had been peer-reviewed and were based on a cohort size of ≥ 100 . All the models examined had validation area under curves (AUCs), which were significantly worse than the area under curves of their derivation cohorts. For example, the AUC of the validation cohort using the model proposed by Chen *et al*⁷ was at best 0.69 (95% confidence interval [CI] 0.66-0.72) compared to the derivation AUC, which was 0.91 (95% CI 0.85-0.97). A similar pattern was noted in the other 3 models.

Gupta⁴ tested 20 candidate prognostic models using data derived from 411 consecutively admitted adults with a PCR-confirmed diagnosis of SARS-CoV-2 in a major London hospital. Five of these models were pre-existing point-based scores not specific for Covid19 (MEWS, REMS, qSOFA, CURB65 and NEWS2) and the remainder of which were a combination of point-based scores and logistic regression models specifically derived from SARS-CoV-2 patients. None of these methods overlapped with those previously tested by El-Solh and 9 of the 15 Covid-specific models had been developed in China. The most discriminating univariable predictor for in-hospital mortality was age (AUC 0.76 [95% CI 0.71-0.81]) and for in-hospital deterioration was oxygen saturation on room air (AUC 0.76 [95% CI 0.71-0.81]). More importantly, none of the models tested performed consistently better than these univariable predictors.

These inconsistencies are an ongoing issue. Bradley⁶ concluded that the overall prognostic performance of established clinical scores (CURB-65, NEWS2 and qSOFA) was generally poor with reference to SARS-CoV-2, while Fan¹¹ concluded the opposite. To illustrate the AUC for CURB65 prognostic score was 0.85 (Fan¹¹), 0.75 (Bradley⁶) and 0.698 (Kodama¹²). This begs the question - why are prognostic scores performing so inconsistently even when tested against cohorts who are similar clinically? We ran these meta-analyses to uncover possible reasons for these inconsistencies. As a secondary goal, we also sought an easily measurable, dependable single-parameter biomarker to predict mortality in swab-positive SARS-CoV-2 patients; especially as there is not always time or resources available to calculate a full prognostic model¹³.

Methods

Data collection

We searched the PubMed database for the keywords 'SARS-CoV-2' in combination with 'biomarker name' and 'mortality'. The period for the first data tranche was set from the emergence of the SARS-CoV-2 pathogen on the 01st December 2019 to 30th June 2021. Two independent reviewers analyzed studies for relevance. All papers reporting mortality data for hospitalized patients swab-positive for SARS-CoV-2 with a biomarker level at presentation (0-48h of admission) were examined for a Receiver Operating Characteristic (ROC) analysis and a corresponding Area under Curve (AUC). When studies failed to quote the margin of error for AUCs, corresponding authors were contacted and their AUC data was included in pooled AUCs if confidence intervals or standard deviations were forthcoming. All studies are displayed in summary figures for completeness. Ethical approval was obtained from the Integrated Research Application System (reference 281880) for analysis of the Cambridge (UK) data. To ensure biomarkers were applicable to acute adult general admissions, we excluded reports of patients already admitted to intensive care or restricted to specific groups (pregnancy, hemodialysis, or transplant patients). Mortality (30-day or in-hospital) was used as the endpoint. The following data was collected from the root studies: a) Area under curve and 95% confidence intervals for the biomarkers examined (admission D-dimer, CRP, IL-6, troponin, urea); b) age of cohort (mean and standard deviation) and number of patients in cohort; c) geographical location of cohort (if a multi-center study, the location of the hospital of the first author was used). Europe/North America and Asia were the sources of most studies and were therefore the focus

of subsequent meta-analyses. This process is summarized in a PRISMA flowsheet depicted in Fig.1. This study is registered with PROSPERO with the CRD42022366893.

To determine the impact of multiple rounds of vaccination and new variants in the SARS-CoV-2 virus, we subsequently repeated the search using the PubMed database from 01st December 2019 to 31st March 2023 using the following combinations of keywords:

- a) 'SARS-CoV-2' in combination with 'vaccination' and 'biomarker name'
- b) 'SARS-CoV-2' in combination with 'variant' and 'biomarker name'
- c) 'Covid19' in combination with 'vaccination' and 'biomarker name'
- d) 'Covid19' in combination with 'variant' and 'biomarker name'

The results were then aggregated and individual papers were checked for a Receiver Operating Characteristic (ROC) analysis and a corresponding Area under Curve (AUC) with respect to a vaccinated cohort or to a proven or very likely variant. As there were very few papers with these data ($n < 5$), we have elected not to perform any analyses but have displayed the raw data in Fig.5 and Table 2. A more detailed explanation is available in the online Supplement.

Statistical analysis

We have used area under curve (AUC) of the Receiver Operating Characteristic as the different studies we examined used different methods of biomarker analyses and/or presented data in

different units of measurement and, hence, were not directly comparable. Also, studies reported biomarker efficacies differently - for example, as odds ratios per unit increase (such as per ng/ml), odds ratio per block unit increase (such as per 5ng/ml) or by dividing at the median and comparing the top half with the bottom half. We needed a simple, reproducible estimate of efficacy that would discount the different methods and units of measurement and the AUC fulfilled this requirement.

To aggregate the data on age and biomarkers from individual studies, the *meta* library in R was used to report overall mean values and 95% confidence intervals and the statistical significance of differences between mean values in the joint European and North American cohort and the Asian cohort. This analysis was based on estimates of standard errors for each study, obtained by assuming values for individual subjects were normally distributed in each study with a study-specific mean. In this way, measures of spread (IQR, SD and range) were converted into estimates of within-study standard deviations. Since the estimates of the study-specific means exhibited high levels of heterogeneity within both categories, a *random effects model* was fitted as opposed to a fixed effects model in the meta-analysis.

Sensitivity analyses

Sensitivity analyses were performed by serially excluding each study to determine the implications of individual studies on the pooled AUC. No individual study had a significant implication for pooled AUCs for either European/North American or the Asian cohorts

(Supplementary Tables 1-5). Note that when fitting a random effects meta-analysis model, the individual study means are assumed to be random, and the between-study heterogeneity (τ^2) needs to be estimated. For the pooled AUC, we used a single estimate of τ^2 based on the overall dataset (both European/North American and the Asian studies) due to small sample sizes, so removing a study affects this and thereby may shift the confidence intervals very slightly for the other subgroup.

Patient and public involvement

We discussed how best to display our data and results with the members of the public and patients. Following this, we have created a free-to-access, publicly-available website (<https://covid19.cimr.cam.ac.uk/>), with a map displaying the source data and links back to the original studies. Root study authors have also volunteered that statistical software is expensive and hence inaccessible. Therefore, we have written a programme in R that allows for the calculation of the AUC of a biomarker which is free to download from the same website. Our intention is that everyone will be able to view the most effective biomarkers for their locale from the website and to calculate an AUC for their own data. Volunteers have also tested the website and software for accessibility and ease of use.

Results

Initially we examined 1,930 articles that were published from the beginning of the SARS-CoV-2 pandemic in 01st December 2019 to 30th June 2021, and selected 131 papers that met our pre-specified selection criteria. This process is summarized in Fig.1 and all reference papers are listed in the References (Meta-analyses) section.

Our meta-analyses have revealed differences in the effectiveness of biomarkers in different regions of the world. These are summarized in Fig.2. For example, admission CRP levels are a good prognostic marker for mortality in Asian countries, with a pooled AUC (area under curve) of 0.83 (95% CI 0.80-0.85) from 34 studies, but only an average predictor of mortality in Europe and North America, with a pooled AUC of 0.67 (95% CI 0.63-0.71) from 21 studies ($P<0.0001$, Fig.3A, Table 1). We see the same pattern for admission D-dimer and IL-6 levels – they are good predictors of mortality in Asian countries (pooled AUCs of 0.78 [95% CI 0.76-0.82]) and 0.86 [95% CI 0.81-0.90] respectively) but not in Europe and North America (pooled AUCs of 0.69 [95% CI 0.66-0.72] and 0.70 [95% CI 0.64-0.75] respectively; $P<0.0001$ for both compared to Asian counterparts; Fig.3B and Fig.4A). This explains why the prognostic scores that are being proposed for SARS-CoV-2 do not perform evenly in different countries, as the ‘building blocks’ underpinning these prognostic scores have intrinsically different effectiveness in different populations.

There are two biomarkers that performed well in all cohorts regardless of geographical location. Admission troponin levels had a pooled AUC of 0.81 [95% CI 0.77-0.85] in Asian

countries and a pooled AUC of 0.79 [95% CI 0.74-0.83] in European and North American countries (Fig.4B). Similarly, urea levels on admission had a pooled AUC of 0.79 [95% CI 0.70-0.85] in Asian countries and a pooled AUC of 0.78 [95% CI 0.74-0.81] in European and North American countries (Fig.4C). This implies that end-organ damage at the time of presentation is a key prognostic indicator of severity for SARS-CoV-2.

It was noted very early on that the elderly fared worse in this pandemic. Therefore, it was reasonable to evaluate whether age itself was a reasonable predictor of mortality, given that this is usually instantaneously available directly from the patient. Interestingly, in the Asian cohorts, age fared less well when compared to all 5 biomarkers examined (Table 1, Fig.2). The exact opposite was seen in the European/North American cohorts, with age (AUC 0.78 [95% CI 0.77-0.80]) outperforming the inflammatory biomarkers (D-dimer, CRP, and IL-6) and being equivalent to the biomarkers showing end-organ damage (urea and troponin).

Pooling all the results from Asian, European, and North American studies gave a false impression of overall effectiveness for CRP, D-dimer, and IL-6 (Table 1). As an example, the pooled AUC for CRP for the entire dataset is 0.78 (95% CI 0.74-0.81). When separated into the regional blocks as previously described it becomes obvious that the Asian studies are skewing the results and masking the fact that admission levels of CRP, D-dimer and IL-6 are simply not very effective in predicting mortality in European and North American countries.

We expected that multiple rounds of vaccinations and ongoing mutations into different strains would significantly impact biomarker efficacy. Therefore, further analyses were conducted to examine this in further detail. There was a paucity of studies where information on vaccination status and viral variant was available, and we could only find 4 studies with sufficient numbers to conduct mortality analyses, which were relevant (Table 2 and Fig.5). It appears that in both the N. American/European and Asian cohorts that the efficacy of D-dimer and CRP as a biomarker for mortality is declining in the vaccinated *versus* the unvaccinated groups. This 'blunting' effect is also observed in the Delta and Omicron waves compared to the original data (Table 2).

Discussion

SARS-CoV-2 represented an unprecedented challenge to the medical, financial, and social frameworks of countries around the world. At the same time, the pandemic has triggered rapid and significant advances in medical technology, including but not limited to messenger RNA vaccines, pragmatic multi-armed trials of interventions, and large-scale production and use of lateral flow testing. From our point of view, SARS-CoV-2 has offered an opportunity to test biomarkers on a worldwide scale; as it is a single clearly defined clinical entity (*e.g.* by PCR-positivity or lack thereof), and a huge amount of data (including mortality data) was available in a very short timeframe from multiple countries.

Therefore we are able to demonstrate what we have long suspected - that biomarker effectiveness for mortality in SARS-CoV-2 varies significantly by geographical location. This important finding has an impact for clinicians using biomarkers and/or prognostic scores derived in other regions to assist the process of decision-making (e.g. whether to admit to intensive care) particularly when 'waves' of infection risk overwhelming local health resources. Consistent with our findings, Marino *et al*¹⁴ demonstrated that a prognostic score developed in the same country (PREDI-CO, Bartoletti *et al*¹⁵, Italy) had reasonable predictive power (AUC of 0.76, 95% CI 0.58-0.93) while a prognostic score developed in another country (Yan-XGBoost, Yan *et al*¹⁶, China) did not perform satisfactorily (AUC of 0.57, 95% CI 0.37-0.76) when applied to their cohort.

This likely applies to other conditions. CURB-65 is well-known and validated as a tool for predicting mortality in community-acquired pneumonia¹⁷, developed in the UK, New Zealand, and the Netherlands. However, it performs less satisfactorily in older populations¹⁸. For example, Shirata *et al*¹⁹ demonstrated that CURB-65 had an AUC of 0.672 (95% CI 0.607-0.732) when applied to patients ≥ 65 years. Since Japan has one of the world's highest life expectancies, it is likely that CURB-65 would not perform as well if applied to a Japanese cohort. Interestingly, CURB-65 also performs poorly when applied to Colombian patients (AUCs of 0.629-0.669 when tested against 3 cohorts)²⁰. Hincapie suggested that this may be due to the factors underpinning a significant difference in community-acquired pneumonia-associated mortality (9.5%¹⁷ versus 17-32%²⁰). Although it has been suspected that this is the case, we note that biomarkers and prognostic scores developed in large multi-center trials in

predominantly developed countries continue to be used in other countries and be incorporated into national guidelines without prior validation. Therefore, we suggest that prognostic biomarkers and scores must be explicitly validated before being used in novel populations. To make this easier, it might be reasonable to suggest that standardized documents for collecting information for the purpose of biomarker validation (such as in the form of downloadable online supplements) be provided by the authors whenever a new biomarker or score is proposed. Then the original manuscript could be updated easily (online) to state that such a score has now been validated in a particular country or target population.

It is not possible to know from these descriptive meta-analyses why there are these regional differences in biomarker effectiveness. The differences might be due to cohort age, different modes of death, genetic backgrounds, treatment effects, and/or various combinations of the above. The Asian cohorts were universally younger than the European/North American cohorts in all five parameters we investigated (CRP, D-dimer, troponin, urea, and IL-6; Table 1). It is possible that younger patients in Asia were dying from cytokine storm (hence the marked prognostic value of the ‘inflammatory’ markers such as CRP, D-dimer, and IL-6), while older people were dying from multi-organ failure in Europe. It is also possible that there has been a ‘training effect’, with the West having had prior warning from the Asian experience. The earlier use of specific anti-inflammatory approaches, in particular steroids and tocilizumab, has most probably blunted the effectiveness of markers such as IL-6 and CRP as predictors of death. Social contact-limiting measures (‘lockdowns’) have likely changed the composition of people falling ill and hence seeking hospital admission.

Our initial study has some limitations that need to be stressed. First, a significant number of studies did not quote 95% confidence intervals (14 of 78 for D-dimer, 18 of 75 for CRP, 3 of 35 for troponin, 1 of 16 for urea, 8 of 38 for IL-6), and we were unable to obtain them despite best efforts to communicate with the authors. These studies are included in Figs.3-4 but are not included in the calculation of the pooled AUCs. Second, insufficient numbers of studies were located in other continents to perform an adequate meta-analysis. Third, the majority of studies in the Asian section were from China (so 34 of 47 studies for CRP were on the Chinese population), and so the result may be representative of the Chinese population rather than of Asian populations in general. Finally, due to the nature of our representative characteristic, we are unable to suggest threshold values for the biomarkers in question.

The other important point we would like to make is that we were woefully underprepared for a health emergency on this scale. Most of the data we have shown is pertinent to the initial viral lineages, and by the time the meta-analyses were performed, novel lineages of clinical relevance, such as Alpha, Delta, and Omicron, have emerged. Moreover, one should note that the area under the curve may not give a complete picture of biomarker efficacy, and there are other measures that could be alternatively applied, e.g., relative risk increase per unit increase of a biomarker, relative risk increase compared to the lower 50%.

The key then lies in being prepared in the case of future threats. We propose that information frameworks be set up ahead of time, and then clinicians and scientists can simply ‘slot in’ their data as it becomes available, such as on a freely accessible website that is publicly available in real-time or as close to that as possible. It may also be wise to have designated centres and staff who will act to provide such data. For example, we mapped the root studies on the following website (<https://covid19.cimr.cam.ac.uk/>) and wrote a free-to-use software program that the healthcare community can use to check whether their biomarker of choice is effective in their population. Given that medical and research staff are likely to be incredibly busy if another pandemic strikes, it would make sense to make sure that as much of the process is as automated as possible, *e.g.* by using dedicated programmes to automatically harvest demographics, biomarkers, and mortality data from medical software administration systems where these are in use. It could be agreed beforehand what data is needed, and this could be set out in modular stages. For example, basic requirements could be age, sex, biomarker(s) levels, and outcome, while secondary outcomes (such as imaging data, complications, and long-term sequelae) could be ‘bolt-on’ options. Furthermore, specific centres could be designated to collect data from specific groups, *e.g.* pregnant women, children, and immunocompromised people. In this way, data collection can be standardized and organized rather than growing organically as was the case in SARS-CoV-2. The availability of such data would not just aid in biomarker identification but also allow the rapid organization of clinical trials by pinpointing ‘at-risk’ groups early who could be targeted for vaccination or intervention programmes. Planning ahead would also allow the ethical permissions for gathering and analysing such data to be applied for and granted beforehand; and for public opinion to be sought in how data can be

used while protecting the confidentiality of individual patients. A good analogy would be preparing for disasters such as earthquakes or fires – plans for these are now accepted as a mandatory part of keeping people safe around the world.

There are drawbacks associated with this approach. Firstly, these steps may only be possible in countries with the funding and resources to undertake them. We note that even now there still is very little data regarding SARS-CoV-2 from less-developed countries. We would urge large health and charitable organisations such as the World Health Organisation to pinpoint this as an area requiring further funding and development, ideally before another pandemic. Second, there would have to be international agreements regarding the use and protection of patient data. There will also be much commercial interest in this kind of data, particularly for the development of vaccines and treatments, and there should be protocols to protect data-harvesting/selling without commensurate benefit to patients who have provided the data.

In short, the SARS-CoV-2 pandemic exerted a terrible toll worldwide. We owe it to ourselves and to future generations to learn from this experience. The principle take-home messages are that biomarkers should be tailored to and validated in their target populations; and that we need to be prepared for rapid information gathering and analyses ahead of another pandemic.

Table 2: Summary of studies with vaccinated cohorts and variant data for the 5 biomarkers investigated.

AUC: area under curve

IL-6: interleukin-6

CRP: C-reactive protein

The reference AUC has been displayed in a coloured font (red for Asian and blue for European/N.American so as to be consistent with the other figures in the manuscript).

*The European/N.American figures have been shown as a reference as approximately 90% of Australia's population has European ancestry.

Figure legends

Figure 1: PRISMA flow diagram for paper review, selection, and inclusion in these meta-analyses.

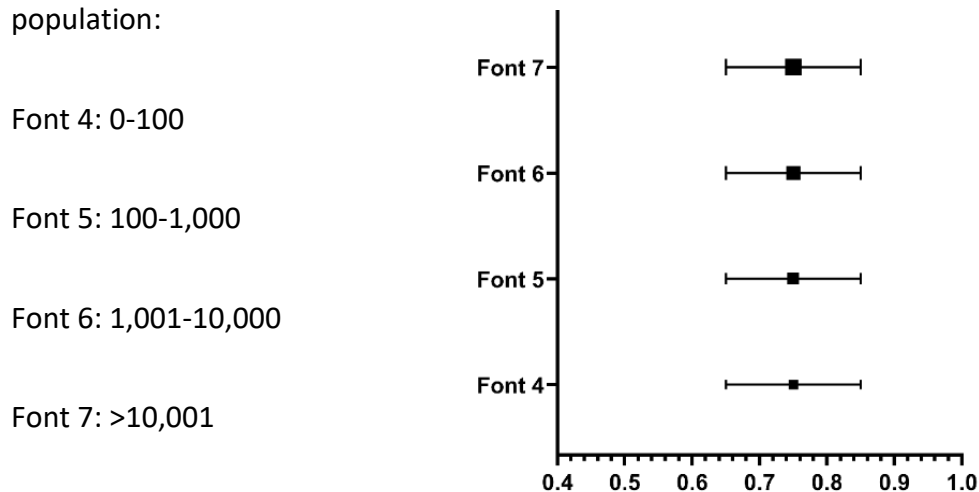

Figure 2: Summary forest plot demonstrating pooled area under curves for the five biomarkers being meta-analyzed (CRP, D-dimer, troponin, urea, and IL-6) and age. For ease of comparison values for Asian countries are shown in red and values for European/North American countries are shown in blue. There was insufficient data to accurately construct pooled AUCs for other geographical regions.

Figure 3: Forest plot demonstrating all individual studies contributing to the meta-analyses for (A) CRP and (B) D-dimer in Asian and European/North American countries for the first tranche of data (from Jan 2020 – June 2021).

Blue diamond: pooled AUC for European/North American countries

Red diamond: pooled AUC for Asian countries

The size of each square representing an individual study corresponds with the size of the study population:

For the reader's ease the data sources are arranged alphabetically both within the figure and in the references (meta-analyses) sections.

Figure 4: Forest plot demonstrating all individual studies contributing to the meta-analyses for (A) IL-6, (B) urea (C) troponin, and (D) age in Asian and European/North American countries for the first tranche of data (from Jan 2020 – June 2021).

Blue diamond: pooled AUC for European/North American countries

Red diamond: pooled AUC for Asian countries

The size of each square representing an individual study corresponds with the size of the study population:

For the reader's ease, the data sources are arranged alphabetically both within the figure and in the references (meta-analyses) sections.

Figure 5: Forest plot demonstrating all individual studies with data relating to a vaccinated cohort or to a cohort with a known variant.

Blue diamond: pooled AUC for European/North American countries

Red diamond: pooled AUC for Asian countries

The size of each square representing an individual study corresponds with the size of the study

population:
