## 45 **Abstract**

46 Human trophoblast stem (**TS**) cells are an informative in vitro model for the generation  
47 and testing of biologically meaningful hypotheses. The goal of this project was to derive patient-  
48 specific TS cell lines from clinically available chorionic villus sampling biopsies. Cell outgrowths  
49 were captured from human chorionic villus tissue specimens cultured in modified human TS cell  
50 medium. Cell colonies emerged early during the culture and cell lines were established and  
51 passaged for several generations. Karyotypes of the newly established chorionic villus-derived  
52 trophoblast stem (**TS<sup>CV</sup>**) cell lines were determined and compared to initial genetic diagnoses  
53 from freshly isolated chorionic villi. Phenotypes of **TS<sup>CV</sup>** cells in the stem state and following  
54 differentiation were compared to cytotrophoblast-derived TS (**TS<sup>CT</sup>**) cells. **TS<sup>CV</sup>** and **TS<sup>CT</sup>** cells  
55 uniformly exhibited similarities in the stem state and following differentiation into  
56 syncytiotrophoblast and extravillous trophoblast cells. Chorionic villus tissue specimens provide  
57 a valuable source for TS cell derivation. They expand the genetic diversity of available TS cells  
58 and are associated with defined clinical outcomes. **TS<sup>CV</sup>** cell lines provide a new set of  
59 experimental tools for investigating trophoblast cell lineage development.

60

## 61 **Summary statement**

62 The chorionic villus-derived trophoblast stem cell lines described in this report enhance  
63 the genetic diversity of available trophoblast stem cell models and are linked to specific clinical  
64 outcomes. They offer a novel set of experimental tools for studying trophoblast cell lineage  
65 development and human placentation.

66

## 67 **Introduction**

68 The placenta is a critical organ that allows the fetus to develop within the female  
69 reproductive tract (Amoroso, 1968). Specialized functions attributed to the placenta are  
70 executed by trophoblast cells (Knöfler et al., 2019, Soares et al., 2018, Turco and Moffett,

71 2019). The trophoblast cell lineage arises from the initial differentiation event of the embryo  
72 (Rossant and Tam, 2017). In the human, trophoblast cells organize into villous and extravillous  
73 structures. A villous is comprised of trophoblast and non-trophoblast cell types and includes a  
74 self-renewing trophoblast cell population referred to as cytotrophoblast (Aplin and Jones, 2021,  
75 Sun et al., 2020). Cytotrophoblast are the progenitors for two differentiated cell populations:  
76 syncytiotrophoblast (**STB**) and extravillous trophoblast cells (**EVT**) (Knöfler et al., 2019, Soares  
77 et al., 2018, Turco and Moffett, 2019). STB have a fundamental role in regulating nutrient and  
78 waste transfer between mother and fetus (Aplin and Jones, 2021), whereas EVT cells exit the  
79 placenta and transform the uterus into an environment supporting placental and fetal  
80 development (Knöfler et al., 2019, Soares et al., 2018). Failures in placentation are the root  
81 cause of an assortment of disorders of pregnancy, including pregnancy loss, preeclampsia,  
82 intrauterine growth restriction, and pre-term birth (Brosens et al., 2019, Burton et al., 2016).  
83 Regulatory mechanisms underlying human cytotrophoblast self-renewal and differentiation have  
84 largely remained elusive.

85  
86 Recently, conditions for capturing and maintaining human trophoblast stem (**TS**) cells in  
87 vitro were described (Okae et al., 2018). Human TS cells have the capacity for self-renewal and  
88 differentiation into STB cells or EVT. This in vitro model system has led to the generation of new  
89 insights into mechanisms regulating human trophoblast cell development (Bhattacharya et al.,  
90 2020, Hornbachner et al., 2021, Ishiuchi et al., 2019, Jaju Bhattad et al., 2020, Muto et al.,  
91 2021, Perez-Garcia et al., 2021, Ruane et al., 2022, Saha et al., 2020, Shannon et al., 2022,  
92 Sheridan et al., 2021, Takahashi et al., 2019, Varberg et al., 2021). Initial human TS cell lines  
93 were derived from blastocysts, or first trimester placental tissue obtained from pregnancy  
94 terminations. Establishment of culture conditions for human TS cells led to the derivation of TS  
95 cells from pluripotent stem cells (Castel et al., 2020, Cinkornpumin et al., 2020, Dong et al.,  
96 2020, Guo et al., 2021, Io et al., 2021, Liu et al., 2020, Wei et al., 2021, Yanagida et al., 2021).

97 These in vitro model systems have provided new insights regarding trophoblast cell  
98 development; however, it is unknown whether the origin of these TS cells was compatible with a  
99 healthy pregnancy outcome.

100

101 Chorionic villus sampling (**CVS**) represents a standard, prenatal care procedure that is  
102 performed between 10-14 weeks of gestation (Stranc et al., 1997). Sampling involves the  
103 removal of a small amount of chorionic villus tissue, for the purpose of genetic testing. Common  
104 indications for retrieving chorionic villus tissue include advanced maternal age, history of  
105 infertility, family history (e.g., sibling with genetic anomalies), or an abnormal noninvasive  
106 prenatal test result (Pisarska et al., 2016, Stranc et al., 1997). In addition to their use in genetic  
107 diagnosis, first trimester chorionic villus tissue has become a robust platform for investigation of  
108 placental pathobiology (Flowers et al., 2021, Gonzalez et al., 2021, Pisarska et al., 2016).

109

110 In this study, we derived patient-specific human TS cell lines from clinically available  
111 chorionic villus tissue. Derivation of TS cell lines from chorionic villus tissue expands the genetic  
112 diversity of available human TS cells and importantly is linked to clinical data describing  
113 pregnancy outcomes.

## 114 **Results**

### 115 **Derivation of TS cells from chorionic villus biopsies**

116 Chorionic villus biopsies were acquired with patient consent as part of standard medical  
117 care. Surplus tissue fragments not used for clinical genetic testing were placed in culture  
118 medium used for the expansion of human TS cells (Takahashi et al., 2019); **Fig. 1A**). Tissue  
119 pieces attached to type IV collagen-coated tissue culture treated plates (**Fig. 1B**). Cell  
120 outgrowths were evident at sites of attachment and expanded over the first several weeks of  
121 culture (**Fig. 1C**). Cells and tissue fragments were passaged prior to reaching confluency and  
122 replated in 24 well plates. Cell colonies emerged after first passage and steadily expanded with  
123 culture medium changes every two days. Colony morphology and growth rates were  
124 heterogeneous for the first few passages but became more homogenous after 5-6 passages.  
125 The morphology of chorionic villus-derived TS (**TS<sup>CV</sup>**) cells was consistent with the morphology  
126 of cytotrophoblast-derived TS cells (**TS<sup>CT</sup>**; **Fig. 1B, Fig. 2A**). **TS<sup>CV</sup>** cell line expansion was  
127 carried out slowly to reduce clonal pressure on derived cells. Cell lines were slowly transitioned  
128 into 6 well and 10 cm plate formats after passages 3-4 and 7-8, respectively (**Fig. 1C**). Newly  
129 established cell lines were cryopreserved beginning at passage 6. Importantly, **TS<sup>CV</sup>** cells  
130 tolerated cryopreservation. Revived cells survived, attached, and proliferated for further  
131 expansion. Overall, **TS<sup>CV</sup>** cell line derivation required approximately three months from sample  
132 acquisition to functional assessments of derived lines.

133  
134 The success rate of **TS<sup>CV</sup>** line derivation was 42%, with ten **TS<sup>CV</sup>** lines (6 XY; 4 XX)  
135 successfully derived from 24 unique patient tissue specimens (15 XY; 9 XX; **Table S1**). Success  
136 in cell line derivation may be impacted by the negative consequences of overnight shipping or  
137 the cellular contents of the tissue fragments but did not appear to be associated with the clinical  
138 karyotype of the CVS specimens. Maternal age range was 30-46 with a mean age of 37.3  
139 years. Maternal and paternal ancestries were self-reported and varied (**Table S1**). Chorionic

140 villus specimen collection ranged from 10-14 weeks gestation with an average gestation age of  
141 12 weeks, 3 days (87 days). The earliest sample was collected at 10 weeks, 6 days gestation  
142 and the latest sample was collected at 14 weeks of gestation. The amount of starting tissue  
143 available for cell line derivation ranged from 5-20 mg with a mean of 8.5 mg of tissue. Clinical  
144 genetics performed on tissue specimens at the time of CVS indicated that 19 samples had  
145 normal karyotypes (13 samples 46, XY and 6 samples 46, XX). Clinical karyotyping of the  
146 remaining five samples reported genomic abnormalities including two samples with trisomy 18  
147 (47, XX, +18 and 47, XY, +18), one sample with trisomy 21 (47, XX, +21), and two samples with  
148 chromosomal translocations (**Table S1**). The ten derived TS<sup>CV</sup> cell lines were from eight  
149 samples with clinically normal karyotypes (TS<sup>CVK01</sup>, TS<sup>CVK05</sup>, TS<sup>CVK09</sup>, TS<sup>CVK19</sup>, TS<sup>CVK21</sup>, TS<sup>CVK22</sup>,  
150 TS<sup>CVK23</sup>, and TS<sup>CVK24</sup>), one with trisomy 21 (TS<sup>CVK08</sup>) and one with a translocation (TS<sup>CVK07</sup>).  
151 Additional phenotypic characterization was performed on a subset of TS<sup>CV</sup> cell lines with 46, XX  
152 or 46, XY karyotypes.

153

#### 154 **Characterization of TS<sup>CV</sup> cells in the stem state**

155 Karyotyping was repeated on TS<sup>CV</sup> cells following line derivation and expansion. Cell line  
156 karyotypes were largely consistent with the clinical karyotyping (**Table S1**). Karyotypes of  
157 TS<sup>CVK01</sup> and TS<sup>CVK24</sup> lines were normal and consistent with the clinical results. TS<sup>CVK09</sup> and  
158 TS<sup>CVK23</sup> cell lines exhibited mosaicism and were not consistent with the clinical results. A subset  
159 of the cells karyotyped for TS<sup>CVK09</sup> were 46, XY. The remaining cells analyzed displayed other  
160 genetic anomalies; however, each individual anomaly was restricted to 1-2 total cells (**Table**  
161 **S1**). A subset of TS<sup>CVK23</sup> cells were identified as mosaic for trisomy 20 (47, XX, +20) following  
162 cell line derivation.

163 TS<sup>CT27</sup> (XX) and TS<sup>CT29</sup> (XY) served as reference standard human TS cell lines (Okoe et  
164 al., 2018) used for comparative characterization of the TS<sup>CV</sup> cell lines. TS<sup>CV</sup> cells were

165 maintained in a stem/proliferative state and propagated beyond the Hayflick limit of 50 cell  
166 divisions for non-stem cells, which is consistent with TS<sup>CT</sup> cell proliferation (Okae et al., 2018).  
167 Established TS<sup>CV</sup> cell lines were assessed for presence of mycoplasma by quantitative  
168 polymerase chain reaction (**qPCR**) and no evidence of contamination was detected. TS<sup>CV</sup> cells  
169 in the stem state grew in discrete colonies and displayed a cobblestone morphology, consistent  
170 with the morphology of cytotrophoblast-derived cell lines, TS<sup>CT27</sup> and TS<sup>CT29</sup> ((Okae et al., 2018);  
171 **Fig. 2A**). TS<sup>CV</sup> cells displayed additional characteristics consistent with their trophoblast cell  
172 identity (Lee et al., 2016), including expression of microRNAs from the Chromosome 19  
173 microRNA cluster (**Fig. 2B; C19MC**; hsa-miR-517a-3p, has-miR-517-5p, and hsa-miR-526b-3p)  
174 and hypomethylation of the E74 Like ETS Transcription Factor 5 (**ELF5**) promoter relative to  
175 induced pluripotent stem (**iPS**) cells (**Fig. 2C**). Overall, TS<sup>CV</sup> and TS<sup>CT</sup> cells cultured in the stem  
176 state displayed similar proliferative, morphologic, microRNA expression, and methylation  
177 properties.

178

### 179 **Analysis of the differentiation capacity of TS<sup>CV</sup> cells**

180 Comparisons of TS<sup>CV</sup> and TS<sup>CT</sup> cell capacities for differentiation into STB and EVT cell  
181 lineages, were performed following cell line derivation (**Fig. 1C**). Assessments of cell  
182 differentiation were routinely performed following 10 passages. Differentiation was assessed at  
183 morphological and functional levels.

184

185 **STB differentiation.** The ability of TS<sup>CV</sup> cells to differentiate into STB was assessed  
186 using the previously described three-dimensional STB (**ST3D**) protocol (Okae et al., 2018). STB  
187 differentiation elicited significant morphological changes, including the formation of suspended  
188 spheroid cell clusters (**Fig. 3A**). Complementary to the morphological changes observed, TS<sup>CV</sup>-  
189 derived STB displayed downregulation of stem state transcripts **TEAD4**, **LRP2**, and **LIN28A**  
190 (**Fig. 3B**) and upregulation of STB lineage-specific transcripts, including cytochrome P450

191 Family 11 Subfamily 1 (**CYP11A1**), chorionic gonadotropin beta 7 (**CGB7**), and syndecan 1  
192 (**SDC1**; **Fig. 3C**). STB differentiated from TS<sup>CV</sup> cells secreted chorionic gonadotropin (**CG**) at  
193 levels comparable to STB differentiated from TS<sup>CT</sup> cells as measured by ELISA (**Fig. 3D**).  
194 Overall, TS<sup>CV</sup>-derived STB had similar cell morphology, expression patterns of signature STB  
195 transcripts, and CG production that is observed in TS<sup>CT</sup>-derived STB.

196

197 **EVT cell differentiation.** Canonical features of EVT cell differentiation observed in TS<sup>CT</sup>  
198 cells were evident in TS<sup>CV</sup> cell lines with normal karyotypes (TS<sup>CVK01</sup>, TS<sup>CVK09</sup>, TS<sup>CVK23</sup>, and  
199 TS<sup>CVK24</sup>), including elongated cell morphology (**Fig. 4A**; **Videos 1-3**) and expression of major  
200 histocompatibility complex, class I, G (**HLA-G**) protein (**Fig. 4B**). EVT cells displayed  
201 downregulation of stem state transcripts **TEAD4**, **LRP2**, and **LIN28A** (**Fig. 4C**). Characteristic  
202 EVT transcripts were upregulated, including **HLA-G**, matrix metalloproteinase 2 (**MMP2**), and C-  
203 C motif chemokine receptor 1 (**CCR1**; **Fig. 4D**). Overall, these TS<sup>CV</sup> stem cell derived EVT cells  
204 were comparable to EVT cells derived from TS<sup>CT</sup> cells.

205

## 206 **Transcriptomic analysis of the developmental potential of TS<sup>CV</sup> cells**

207 To obtain a broad comparative assessment of TS<sup>CV</sup> and TS<sup>CT</sup> in stem, STB, and EVT  
208 differentiated cell states, transcriptomes were captured using RNA-sequencing (**RNA-seq**). STB  
209 differentiation from the stem state resulted in broad changes in gene expression in TS<sup>CT</sup> cells  
210 (TS<sup>CT27</sup>, TS<sup>CT29</sup>; **Fig. 5A**; **Table S2**) and TS<sup>CV</sup> cells (TS<sup>CVK01</sup>, TS<sup>CVK09</sup>, TS<sup>CVK23</sup>, and TS<sup>CVK24</sup>; **Fig.**  
211 **5B**; **Table S3**), including downregulation of stem markers **EPCAM**, **LIN28A**, **LRP2**, **PEG10**, and  
212 **TEAD4** and upregulation of STB markers **CGB2**, **CGB7**, **CYP11A1**, **CYP19A1**, and **SDC1**. STB  
213 differentiation-induced changes in gene expression were consistent between TS<sup>CT</sup> (TS<sup>CT27</sup> and  
214 TS<sup>CT29</sup>) and TS<sup>CV</sup> (TS<sup>CVK01</sup>, TS<sup>CVK09</sup>, TS<sup>CVK23</sup>, and TS<sup>CVK24</sup>) cells (R=0.87, p<2.23-16; **Fig. 5C**).

215 EVT cells successfully differentiated from the stem state exhibited broad gene  
216 expression changes in TS<sup>CT</sup> (TS<sup>CT27</sup>, TS<sup>CT29</sup>; **Fig. 5D**; **Table S4**) and TS<sup>CV</sup> cell lines with normal

217 karyotypes (TS<sup>CVK01</sup>, TS<sup>CVK09</sup>, TS<sup>CVK23</sup>, and TS<sup>CVK24</sup>; **Fig. 5E**; **Table S5**). These changes included  
218 the downregulation of stem markers *EPCAM*, *LIN28A*, *LRP2*, *PEG10*, and *TEAD4* and  
219 upregulation of EVT cell markers *CCR1*, *HLA-G*, *ITGA1*, *MMP2*, and *NOTUM*. Gene expression  
220 changes induced by EVT cell differentiation were consistent between TS<sup>CT</sup> (TS<sup>CT27</sup> and TS<sup>CT29</sup>)  
221 and TS<sup>CV</sup> (TS<sup>CVK01</sup>, TS<sup>CVK09</sup>, TS<sup>CVK23</sup>, and TS<sup>CVK24</sup>) cells (R=0.85, p<2.23-16; **Fig. 5F**).

222 Principal component analysis of TS<sup>CT</sup> and TS<sup>CV</sup> cell lines identified three primary cell-  
223 state specific clusters (**Fig. 5G**). TS<sup>CV</sup> cells displayed consistent clustering in the stem state and  
224 following STB and EVT cell lineage differentiation (**Fig. 5G**). Results from correlation analyses  
225 performed to compare cell expression profiles are indicative of comparable transcriptomic  
226 changes across TS<sup>CV</sup> and TS<sup>CT</sup> cell lines (**Fig. 5H**). Overall, these results indicate that TS<sup>CV</sup> cells  
227 are capable of self-renewal and effective differentiation into both STB and EVT cell lineages and  
228 can be considered bonafide TS cells.

229

## 230 **Discussion**

231 Our understanding of placenta development and function has benefitted from the  
232 availability of in vitro model systems. In the human, these model systems have included primary  
233 cell and explant cultures, choriocarcinoma-derived cell lines, and immortalized cell lines (Ringler  
234 and Strauss, 1990, Shibata et al., 2020). Each in vitro approach has had merits but also  
235 limitations (Lee et al., 2016, Soares et al., 2018). Over two decades ago, Rossant and  
236 colleagues reported a procedure for culturing TS cells from the mouse (Tanaka et al., 1998).  
237 These cells could be maintained in a proliferative stem state or induced to differentiate.  
238 Furthermore TS cells could be reintroduced into blastocysts and shown to possess the capacity  
239 to contribute to mouse placentas (Tanaka et al., 1998). Mouse TS cells became an effective  
240 model system to elucidate gene regulatory networks controlling trophoblast cell differentiation  
241 and placental development (Hada et al., 2022, Hemberger et al., 2020, Latos and Hemberger,  
242 2016, Lee et al., 2019). Efforts ensued to establish TS cells in other species with some success

243 (Asanoma et al., 2011, Grigor'eva et al., 2009) but human TS cells represented an enigma  
244 (Kunath et al., 2014, Shibata et al., 2020). Culture protocols for sustaining mouse TS cells were  
245 ineffective in the human (Kunath et al., 2014). The discovery of culture conditions for  
246 propagating and differentiating human TS cells represented a major advancement (Okae et al.,  
247 2018). Utilizing these human TS cell culture tools, we have demonstrated the feasibility of  
248 capturing and expanding authentic TS cells from human chorionic villus specimens. Unique to  
249 these newly derived stem cells is the ability to obtain clinical outcomes that can be used to study  
250 placental development leading to healthy outcomes and disease states.

251

252         The initial human TS cell lines were derived from either blastocysts or first trimester  
253 pregnancy terminations (Okae et al., 2018). These human TS cell lines represent the  
254 benchmark for all TS cell lines subsequently derived. Chorionic villus biopsies are an alternative  
255 tissue source for deriving TS cells. They are retrieved during the first trimester of pregnancy as  
256 part of standard medical care (Adusumalli et al., 2007, Dong et al., 2003, McIntosh et al., 1993,  
257 Pisarska et al., 2016, Stranc et al., 1997, Wang et al., 1994, Williams et al., 1992, Williams et  
258 al., 1987). Thus, chorionic villus-derived TS cell lines can be connected to robust pregnancy  
259 outcome information. Human TS cell lines have also been derived from miscarriages (Saha et  
260 al., 2020), term human placenta tissue (Wang et al., 2022), and reprogrammed from pluripotent  
261 stem cells (Castel et al., 2020, Cinkornpumin et al., 2020, Dong et al., 2020, Guo et al., 2021, lo  
262 et al., 2021, Jang et al., 2022, Liu et al., 2020, Soncin et al., 2022, Viukov et al., 2022, Wei et  
263 al., 2021, Yanagida et al., 2021). These alternative TS cell models are potentially useful tools for  
264 investigating trophoblast cell development but each offer caveats for consideration. TS cells  
265 derived from trophoblast tissue obtained from miscarriages may best contribute to  
266 understanding trophoblast cell-related mechanisms linked to pregnancy failure and the impact of  
267 a failed pregnancy on TS cells. TS cells recovered from term placental tissue reflect the  
268 culmination of events transpiring throughout the duration of pregnancy, as epigenomic

269 differences are observed in the placenta during gestation (Flowers et al., 2021, Gonzalez et al.,  
270 2021). Pluripotency is established through extensive genomic reprogramming (Hanna et al.,  
271 2010, Papp and Plath, 2013), which minimizes the impact of the epigenetic landscape  
272 established during pregnancy on the TS cell phenotype. It is reasonable to assume that genetic  
273 background and source of trophoblast tissue for TS derivation will influence TS cell behavior.  
274 Culturing TS cells under optimized conditions may normalize some features attributed to an  
275 adverse pregnancy and maternal environment, whereas in other cases the aberrant behavior  
276 may persist. Advantages of using chorionic villus-derived TS cells for investigating trophoblast  
277 cell-gene regulatory networks contributing to placental development are evident.

278  
279 TS cell lines were successfully derived from chorionic villus biopsies possessing both  
280 normal and abnormal karyotypes. TS cells with a triploid karyotype have also been established  
281 from human blastocysts (Kong et al., 2022). Most recently, trophoblast organoids with abnormal  
282 karyotypes have been derived from chorionic villus biopsies (Schaffers et al., 2022). Chorionic  
283 villus-derived TS cell lines could be interrogated in the stem state and following differentiation  
284 into either STB or EVT cell lineages. The phenotypic and functional parameters evaluated  
285 revealed similarities between cytotrophoblast and chorionic villus-derived TS cells when  
286 cultured for stem state maintenance or following STB and EVT cell differentiation. Some  
287 differences in the capacity for EVT cell differentiation among chorionic villus-derived TS cells  
288 were noted. Variability in the capacity for human TS cell line differentiation into EVT cells has  
289 been previously reported (Cinkornpumin et al., 2020, Haider et al., 2022, Okae et al., 2018,  
290 Shannon et al., 2022). Numerous factors such as unreported clinical characteristics, undetected  
291 genomic differences, or inherent sample variability could be contributing to the differences  
292 observed. Thus, chorionic villus-derived TS cells represent a unique in vitro model to investigate  
293 functional variability in TS cells isolated from a temporally relevant tissue source. The true  
294 impact of the chromosomal abnormalities on TS cells and their differentiation into STB or EVT

295 cells will require successful cultivation and characterization of multiple cell lines possessing the  
296 same abnormal karyotype.

297

298 Mosaicism is a characteristic feature of the human placenta (Coorens et al., 2021,  
299 Robinson and Del Gobbo, 2021, Yuen and Robinson, 2011). Trophoblast cells possess a  
300 tolerance for karyotypic abnormalities not evident in the embryo or fetus (Coorens et al., 2021,  
301 Shahbazi et al., 2020, Yuen and Robinson, 2011). Each cotyledon of the placenta exhibits  
302 elements of trophoblast cell clonality (Coorens et al., 2021). Placental mosaicism is manifested  
303 in genetic and functional differences among cotyledons within a human placenta (Coorens et al.,  
304 2021, Huang et al., 2009, Rubin et al., 1993, Wang et al., 1993). Among the TS cell lines  
305 derived from chorionic villus biopsies, some exhibited a karyotype consistent with the karyotype  
306 of chorionic villus tissue used for the clinical genetic analysis, whereas others differed. Chorionic  
307 villus biopsies contain a mixture of trophoblast and extraembryonic mesoderm (Aplin and Jones,  
308 2021). Thus, differences in TS cell versus chorionic villus tissue could be attributed to confined  
309 placental mosaicism or alternatively, linked to an unappreciated consequence of culture  
310 conditions required to establish the TS cell lines.

311

312 In summary, the generation of chorionic villus biopsy-derived human TS cell lines  
313 expand the genetic diversity of existing TS cell lines available for basic research and importantly  
314 provides an opportunity to associate pregnancy outcomes with trophoblast cell biology. The  
315 research also offers insights into the significance of genetic anomalies and mosaicism in  
316 trophoblast cell development and introduces a novel precision medicine approach to the study  
317 of placentation.

318

## 319 **Materials and Methods**

### 320 **Chorionic villus tissue collections, karyotypic analysis, and clinical phenotyping**

321 Chorionic villus tissue was obtained by highly experienced perinatologists as part of  
322 standard medical care between 10-14 weeks of gestation for clinical genetic diagnosis at  
323 Cedars-Sinai Medical Center (Huang et al., 2009, Pisarska et al., 2016). Clinical cytogenetic  
324 analysis was performed on tissue specimens by direct and long-term culture and reviewed by a  
325 team of cytogeneticists (Huang et al., 2009). Residual trophoblast tissue fragments not required  
326 for clinical cytogenetic analysis were recovered, suspended in Complete TS Cell Medium  
327 [DMEM/F12 (11320033, Thermo Fisher, Waltham, MA), 100  $\mu$ M 2-mercaptoethanol, 0.2%  
328 (vol/vol) fetal bovine serum (**FBS**), 50  $\mu$ M penicillin, 50 U/mL streptomycin, 0.3% bovine serum  
329 albumin (**BSA**, BP9704100, Thermo Fisher), 1% Insulin-Transferrin-Selenium-Ethanolamine  
330 (**ITS-X**) solution (vol/vol, 51500056, Thermo Fisher)], 8.5  $\mu$ M L-ascorbic acid (A8960, Sigma-  
331 Aldrich, St. Louis, MO), 50 ng/mL epidermal growth factor (**EGF**, E9644, Sigma-Aldrich), 2  $\mu$ M  
332 CHIR99021 (04-0004, Reprocell, Beltsville, MD), 0.5  $\mu$ M A83-01 (04-0014, Reprocell), 1  $\mu$ M  
333 SB431542 (04-0010, Reprocell), 800  $\mu$ M valproic acid (P4543, Sigma-Aldrich), and 5  $\mu$ M  
334 Y27632 (04-0012-02, Reprocell)] (Okae et al., 2018), shipped overnight to the University of  
335 Kansas Medical Center, and used for TS cell derivation. Demographic data was collected from  
336 patients and included, parental ages, races and ethnicities, and ancestry (**Table S1**).

337

### 338 **Derivation of TS cells from chorionic villus tissue specimens**

339 Chorionic villus biopsy tissue fragments were dissected and transferred in complete  
340 human TS cell medium. Briefly, individual villus fragments were minced and transferred to a  
341 1.7mL tube, washed with PBS, and centrifuged at 500 x g for 3 min. Tissue pellets were  
342 resuspended in HBSS (with  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ ) supplemented with 1.25U/ml dispase II, 0.4mg/ml  
343 collagenase IV and 80 U/ml DNase I. Samples were then agitated for 15 min at 37°C. After  
344 incubation, tissue suspensions were centrifuged at 500 x g for 3 min. and washed with basal TS  
345 cell medium. Finally, cells and tissue suspensions were centrifuged at 500 x g for 3 min,  
346 resuspended in complete human TS cell medium and plated in 5 mg/mL Corning® mouse type

347 IV collagen (35623, Discovery Labware Inc., Billerica, MA) coated dishes containing complete  
348 human TS cell medium. Cells and remaining tissue fragments attached within 2-5 days. Medium  
349 was replaced with fresh TS cell culture medium after initial attachment and every two days  
350 thereafter. Time to first passage was unique to each sample and determined by the extent of the  
351 outgrowth, but commonly occurred around 21 days post plating. Cells and attached tissue  
352 fragments were washed with PBS and detached with TrypLE Express (12604021, Thermo  
353 Fisher). Cell and tissue fragments were replated in human TS cell culture conditions in a 24 well  
354 plate format. Colonies emerged after the first passage. Cells were maintained in 24 well plate  
355 format for 3-5 passages and then expanded into 6 well plate format.

356

### 357 **TS cell culture**

358       Following TS cell derivation, TS cells were cultured in dishes pre-coated with iMatrix511  
359 (1:2000 dilution; NP892-01, Reprocell). TS cells were maintained in Modified Complete TS Cell  
360 Medium [DMEM/F12 (11320033, Thermo Fisher), 50 U/mL penicillin, 50 µg/mL streptomycin,  
361 0.15% BSA (BP9704100, Thermo Fisher), 1% ITS-X solution (vol/vol; 51500056, Thermo  
362 Fisher)], 200 µM L-ascorbic acid (A8960, Sigma-Aldrich), 1% KnockOut Serum Replacement  
363 (**KSR**, 10828028, Thermo Fisher), 25 ng/mL EGF (E9644, Sigma-Aldrich), 2 µM CHIR99021  
364 (04-0004, Reprocell), 5 µM A83-01 (04-0014, Reprocell), 800 µM valproic acid (P4543, Sigma-  
365 Aldrich), and 2.5 µM Y27632 (04-0012-02, Reprocell)] (Takahashi et al., 2019) medium was  
366 replaced every two days of culture. TS<sup>CT27</sup> (XX) and TS<sup>CT29</sup> (XY) (Okoe et al., 2018) were used  
367 as reference lines.

368

### 369 **STB differentiation**

370       To induce STB cell differentiation, TS cells were plated into 6 cm petri dishes at a  
371 density of 300,000 cells per dish and cultured in ST3D Medium [DMEM/F12 (11320033, Thermo  
372 Fisher), 50 U/mL penicillin, 50 µg/mL streptomycin, 0.15% BSA (BP9704100, Thermo Fisher),

373 1% ITS-X solution (vol/vol; 51500056, Thermo-Fisher)], 200  $\mu$ M L-ascorbic acid (A8960, Sigma-  
374 Aldrich), 5% KSR (10828028, Thermo Fisher), 2.5  $\mu$ M Y27632 (04-0012, Reprocell), 2  $\mu$ M  
375 forskolin (F6886, Sigma-Aldrich), and 50 ng/mL of EGF (E9644, Sigma-Aldrich)](Okae et al.,  
376 2018). On day 3 of cell differentiation, 3 mL of fresh ST3D medium was added to the culture  
377 dishes. Cells were analyzed on day 6 of STB cell differentiation.

378

### 379 **EVT cell differentiation**

380 EVT cell differentiation was induced by plating human TS cells onto 6-well plates pre-  
381 coated with 1  $\mu$ g/mL of mouse type IV collagen at a density of 80,000 cells per well. Cells were  
382 cultured in EVT Differentiation Medium [DMEM/F12 (11320033, Thermo Fisher), 100  $\mu$ M 2-  
383 mercaptoethanol, 50 U/mL penicillin, 50  $\mu$ g/mL streptomycin, 0.3% bovine serum albumin  
384 (BP9704100, Thermo Fisher), 1% Insulin-Transferrin-Selenium-Ethanolamine solution (vol/vol;  
385 51500056, Thermo Fisher)], 100 ng/mL of neuregulin 1 (**NRG1**, 5218SC, Cell Signaling,  
386 Danvers, MA), 7.5  $\mu$ M A83-01 (04-0014, Reprocell), 2.5  $\mu$ M Y27632 (04-0012, Reprocell), 4%  
387 KSR (10828028, Thermo Fisher), and 2% Matrigel<sup>®</sup> (CB-40234, Thermo Fisher). On day 3 of  
388 EVT cell differentiation, the medium was replaced with EVT Differentiation Medium excluding  
389 NRG1 and with a reduced Matrigel<sup>®</sup> concentration of 0.5%. On day 6 of EVT cell differentiation,  
390 the medium was replaced with EVT Differentiation Medium with a Matrigel<sup>®</sup> concentration of  
391 0.5% and excluding NRG1 and KSR. Cells were analyzed on day 8 of EVT cell differentiation.

392

### 393 **Cell line karyotyping**

394 Chromosome analysis of TS<sup>CV</sup> cells was performed using standard cytogenetic methods  
395 (Huang et al., 2009, Pisarska et al., 2016). GTG banded chromosomes were analyzed at 450-  
396 550 band levels. Cytogenetic and fluorescence in situ hybridization results were described  
397 according to the current International Standing Committee on Human Cytogenetic  
398 Nomenclature (ISCN, 2009).

399

#### 400 **Immunocytochemical analysis**

401 Cells were fixed with 4% paraformaldehyde (Sigma-Aldrich) for 15 min at room  
402 temperature. Fixed cells were incubated with primary antibody against HLA-G (ab52455,  
403 Abcam), followed by Alexa488-conjugated goat-anti-mouse immunoglobulin G (**IgG**; A32723,  
404 Thermo Fisher Scientific) secondary antibody and 4',6-diamidino-2-phenylindole (**DAPI**;  
405 Molecular Probes, Eugene, OR). Fluorescence images were captured on a Nikon 80i upright  
406 microscope (Nikon) with a Photometrics CoolSNAP-ES monochrome camera (Roper  
407 Technologies, Inc., Sarasota, FL).

408

#### 409 **iPS cell culture**

410 Human iPS cells were propagated in tissue culture plates pre-coated with Matrigel<sup>®</sup>  
411 (1:100 dilution; 356231, Corning Life Sciences, Tewksbury, MA). iPS cells were maintained in  
412 complete iPS Cell Medium [mTeSR1 Basal Medium + mTeSR1 5X Supplement (85850,  
413 STEMCELL Technologies, Inc., Vancouver, CA) and 10  $\mu$ M Y27632 (04-0012-02, Reprocell)]  
414 and incubated at 37°C and 5% CO<sub>2</sub>. After the first day of culture, cells were cultured in complete  
415 iPS cell medium without Y27632. Medium was replaced every other day of culture. Cells were  
416 passaged or harvested at 80% confluency.

417

#### 418 **miRNA isolation, cDNA preparation, and quantitative real-time PCR**

419 Total RNA was isolated using mirVana kit (AM1560, Thermo Fisher), and RNA  
420 concentration was measured with the Qubit<sup>™</sup> RNA BR Assay Kit (Thermo Fisher). cDNA  
421 synthesis was performed with TaqMan<sup>®</sup> Advanced miRNA cDNA Synthesis kit (A28007,  
422 Thermo Fisher). RT-qPCR was performed using TaqMan<sup>™</sup>Fast Advanced Master Mix  
423 (4444556, Thermo Fisher) and targeted miRNAs MIR517a-3p, MIR517-5p, MIR-526b-3p, and  
424 housekeeping miRNA MIR103a-3p (479485\_mir, 478996\_mir, and 478253\_mir; TaqMan<sup>™</sup>

425 Advanced miRNA Assays, Thermo Fisher; **Table S6**). Relative expression of each transcript  
426 was calculated using  $\Delta\Delta CT$  method and normalized to hsa-miR-103a-3p.

427

#### 428 **Methylation analysis**

429 Genomic DNA was isolated using the DNeasy Blood and Tissue Kit (69504, Qiagen,  
430 Germantown, MD), and 500 ng of DNA was bisulfite converted using the EZ DNA Methylation-  
431 Gold Kit (D5005, Zymo Research, Irvine, CA) according to instructions. Following bisulfite  
432 conversion, the ELF5 promoter region was amplified using a nested PCR approach with  
433 previously reported primers (Primer Set A: forward: 5'-GGAAATGATGGATATTGAATTTGA-3';  
434 reverse: 5'-CAATAAAAATAAAAACACCTATAACC-3' Primer Set B: forward: 5'-  
435 GAGGTTTTAATATTGGGTTTATAATG-3'; reverse: 5'-ATAAATAACACCTACAAACAAATCC-3';  
436 **Table S7**; (Lee et al., 2016, Soncin et al., 2022). PCR was performed with a hot start DNA  
437 polymerase, ZymoTaq (E2001, Zymo Research). After the second PCR, Taq polymerase-  
438 amplified PCR products were gel-purified with QIAquick Gel Extraction Kit (28706X4, Qiagen),  
439 using manufacturer protocols. The purified DNA was inserted directly into a plasmid vector  
440 using TOPO® TA Cloning® Kits for Sequencing (450030, Thermo Fisher) according to  
441 manufacturer instructions. One microliter of purified PCR product was cloned into the plasmid  
442 vector (pCR™4-TOPO®) for 5 min at room temperature. Competent *E. coli* cells were  
443 transformed with the pCR4-TOPO construct, cultured, and minipreps were prepared using the  
444 QIAprep Spin Miniprep Kit (27106X4, Qiagen). Purified DNA was sequenced (GENEWIZ, South  
445 Plainfield, NJ).

446

#### 447 **CG enzyme-linked immunosorbent assay (ELISA)**

448 Conditioned medium was collected following six days of STB culture for each cell line.  
449 CG levels were measured using an ELISA kit (HC251F, Calbiotech), following the  
450 manufacturer's protocol. The measurements were normalized to total cell protein content.

451

## 452 **RNA isolation and RT-qPCR**

453 Total RNA was isolated using TRIzol<sup>®</sup>/chloroform precipitation (15596018, Thermo  
454 Fisher) as previously reported (Varberg et al., 2021). cDNA was synthesized from 1 µg of total  
455 RNA using the High-Capacity cDNA Reverse Transcription Kit (4368813, Thermo Fisher) and  
456 diluted 10 times with ultra-pure distilled water. qPCR was performed using PowerSYBR<sup>®</sup> Green  
457 PCR Master Mix (4367659, Thermo Fisher) and primers (250 nM each). RT-qPCR primer  
458 sequences are presented in **Table S8**. Amplification and fluorescence detection were measured  
459 with a QuantStudio 5 Flex Real-Time PCR System (Thermo Fisher). An initial step (95°C, 10  
460 min) preceded 40 cycles of a two-step PCR (92°C, 15 s; 60°C, 1 min) and was followed by a  
461 dissociation step (95°C, 15 s; 60°C, 15 s; 95°C 15 s). The comparative cycle threshold method  
462 was used for relative quantification of the amount of mRNA for each sample normalized to the  
463 housekeeping genes *B2M* or *POLR2A*.

464

## 465 **RNA library preparation and RNA-Seq**

466 Stranded mRNA-sequencing was performed on the Illumina NovaSeq 6000 Sequencing  
467 System in the Genomics Core at the University of Kansas Medical Center. Quality control was  
468 completed with the RNA Screen Tape Assay kit (5067-5576, Agilent Technologies, Santa Clara,  
469 CA) on the Agilent TapeStation 4200. Total RNA (1 µg) was processed in the following steps: i)  
470 oligo dT bead capture of mRNA, ii) fragmentation, iii) reverse transcription, iv) cDNA end repair,  
471 v) Unique Dual Index (**UDI**) adaptor ligation, vi) strand selection, and vii) library amplification  
472 using the Universal Plus mRNA-Seq with NuQuant library preparation kit (0520-A01, Tecan  
473 Genomics, Männedorf, Switzerland). Library validation was performed with the D1000 Screen  
474 Tape Assay kit (5067-5582, Agilent Technologies) on the Agilent Tape Station 4200. Library  
475 concentrations were determined with the NuQuant module using a Qubit 4 Fluorometer (Thermo

476 Fisher). Libraries were pooled based on equal molar amounts and the multiplexed pool was  
477 quantified, in triplicate, using the Roche Lightcycler96 with FastStart Essential DNA Green  
478 Master (06402712001, Roche, Indianapolis, IN) and KAPA Library Quant (Illumina, Inc., San  
479 Diego, CA) DNA Standards 1-6 (KK4903, KAPA Biosystems, Wilmington, MA). Using the qPCR  
480 results, the RNA-Seq library pool was adjusted to 2.125 nM for multiplexed sequencing. Pooled  
481 libraries were denatured with 0.2 N NaOH (0.04N final concentration), neutralized with 400 mM  
482 Tris-HCl, pH 8.0, and diluted to 425 pM. Onboard clonal clustering of the patterned flow cell was  
483 performed using the NovaSeq 6000 S1 Reagent Kit (200 cycle, 20012864, Illumina). A 2x101  
484 cycle sequencing profile with dual index reads was completed using the following sequence  
485 profile: Read 1 – 101 cycles x Index Read 1 – 8 cycles x Index Read 2 – 8 cycles x Read 2 –  
486 101 cycles. Sequence data were converted from .bcl to FASTQ file format using bcl2fastq  
487 software and de-multiplexed. Raw FASTQ files were trimmed using default parameters (-r 0.1 -d  
488 0.03) in Skewer (Version 0.2.2) and reads shorter than 18 bp were discarded. Transcripts were  
489 quantified using Kallisto (Version 0.46.2). Differentially expressed genes (FDR of 0.05) were  
490 discovered using the Bioconductor package DESeq2 in R (Version 1.32.0).

491

## 492 **Live cell imaging**

493 Cells were placed into an EVOS Onstage Incubator attached to an EVOS FL Automated  
494 Imaging System (Thermo Fisher). The live cell chamber was maintained at constant  
495 temperature (37°C), humidity, and 5% CO<sub>2</sub>. For stem culture, TS cells were maintained in stem  
496 state culture conditions described above and images were acquired 1-2 days after passage and  
497 immediately following culture medium change. EVT cell differentiation was induced as described  
498 above. On the fourth day of the EVT cell differentiation protocol, cells were placed into the live  
499 cell chamber. Phase contrast images were acquired every 10 min continuously from days 2-4 of  
500 stem cell growth or day 4-6 of EVT cell differentiation.

501

502 **Mycoplasma testing**

503 Mycoplasma presence was assessed using the LookOut® Mycoplasma qPCR Detection  
504 Kit (MP0040A, Sigma-Aldrich). Kit protocols were followed as described.

505

506 **Data availability**

507 All raw and processed sequencing data generated in this study have been submitted to  
508 the NCBI Gene Expression Omnibus (GEO; <https://www.ncbi.nlm.nih.gov/geo/>).

509

510 **Code availability**

511 Only publicly available tools were used for data analysis and are described where  
512 relevant in the methods.

513

514 **Materials availability**

515 Materials will be made available upon reasonable request to the investigators.

516

517 **Statistical analysis**

518 Statistical analysis was completed with the GraphPad Prism 9 software. Welch's *t* tests,  
519 Brown-Forsythe and Welch ANOVA tests were applied when appropriate. The figures depict the  
520 data represented as mean  $\pm$  standard deviation with a statistical significance level of  $p < 0.05$ .

521

522 **Study Approval**

523 All human tissue specimens used for research purposes were collected following  
524 informed written consent, deidentified, and approved by institutional review boards at both  
525 Cedars-Sinai Medical Center and at the University of Kansas Medical Center.

526

527 **Acknowledgements**

528 We thank Stacy Oxley and Brandi Miller for their administrative assistance and Clark  
529 Bloomer and Rosanne Skinner in the KUMC Genome Sequencing Facility for their work in  
530 library preparation and DNA sequencing. The research was supported by a National Institutes of  
531 Health (NIH) National Research Service Award postdoctoral fellowship (F32HD096809) and  
532 pathway to independence award (K99HD107262) to K.M.V., NIH grants (MDP: AI154535; MJS:  
533 HD020676, HD099638, HD105734), and the Sosland Foundation.

#### 534 **Author contributions**

535 K.M.V., A.M., M.D.P, and M.J.S. conceived and designed the research; A.N., J.W., and  
536 M.D.P. collected and obtained tissue specimens. J.G., I.S., H.O., and T.A. provided reagents,  
537 protocols, or equipment; K.M.V., A.M., B.M., and K.I., performed experiments and/or analyzed  
538 data; K.M.V, A.M., J.G, I.S., M.D.P, and M.J.S. interpreted results of experiments; K.M.V., A.M.,  
539 J.M.V., and M.J.S. prepared figures and drafted manuscript; K.M.V., A.M., M.D.P, and M.J.S.  
540 edited and revised manuscript; All authors approved final version of manuscript.

541

#### 542 **Competing Interest Statement**

543 There is no conflict of interest that could be perceived as prejudicing the impartiality of  
544 the research reported.

545

#### 546 **Diversity and inclusion statement**

547 We are committed to promote diversity and inclusion in our research. Our team  
548 comprises individuals from varied backgrounds, and we seek to ensure equitable representation  
549 and recognition in our work and collaborations.

804 **Fig. 1 Deriving TS cells from chorionic villus tissue specimens. A)** Simplified schematic  
 805 depicting the process of obtaining chorionic villi tissue fragments, derivation of TS cells, and  
 806 then subsequent differentiation into STB and EVT cell lineages. Created with BioRender.com.  
 807 **B)** Chorionic villus tissue fragments attach and form cellular outgrowths within a few days of  
 808 initial plating. Within one to two weeks the outgrowths expand and proliferate across the well.  
 809 Two to three weeks after plating, the cells were passaged, and colonies emerged. Colony  
 810 clusters were initially small but proliferated and grew rapidly. Significant heterogeneity is present  
 811 initially, but subsequent passaging selects for a TS cell population that displays a similar  
 812 morphology to the original TS cell lines (Okoe et al., 2018), which possess the ability to

813 differentiate into STB and EVT cell lineages. Scale bar represents 250  $\mu\text{m}$  in first panel. All  
814 other scale bars represent 500  $\mu\text{m}$ . **C)** An example timeline for TS cell line derivation and  
815 characterization.

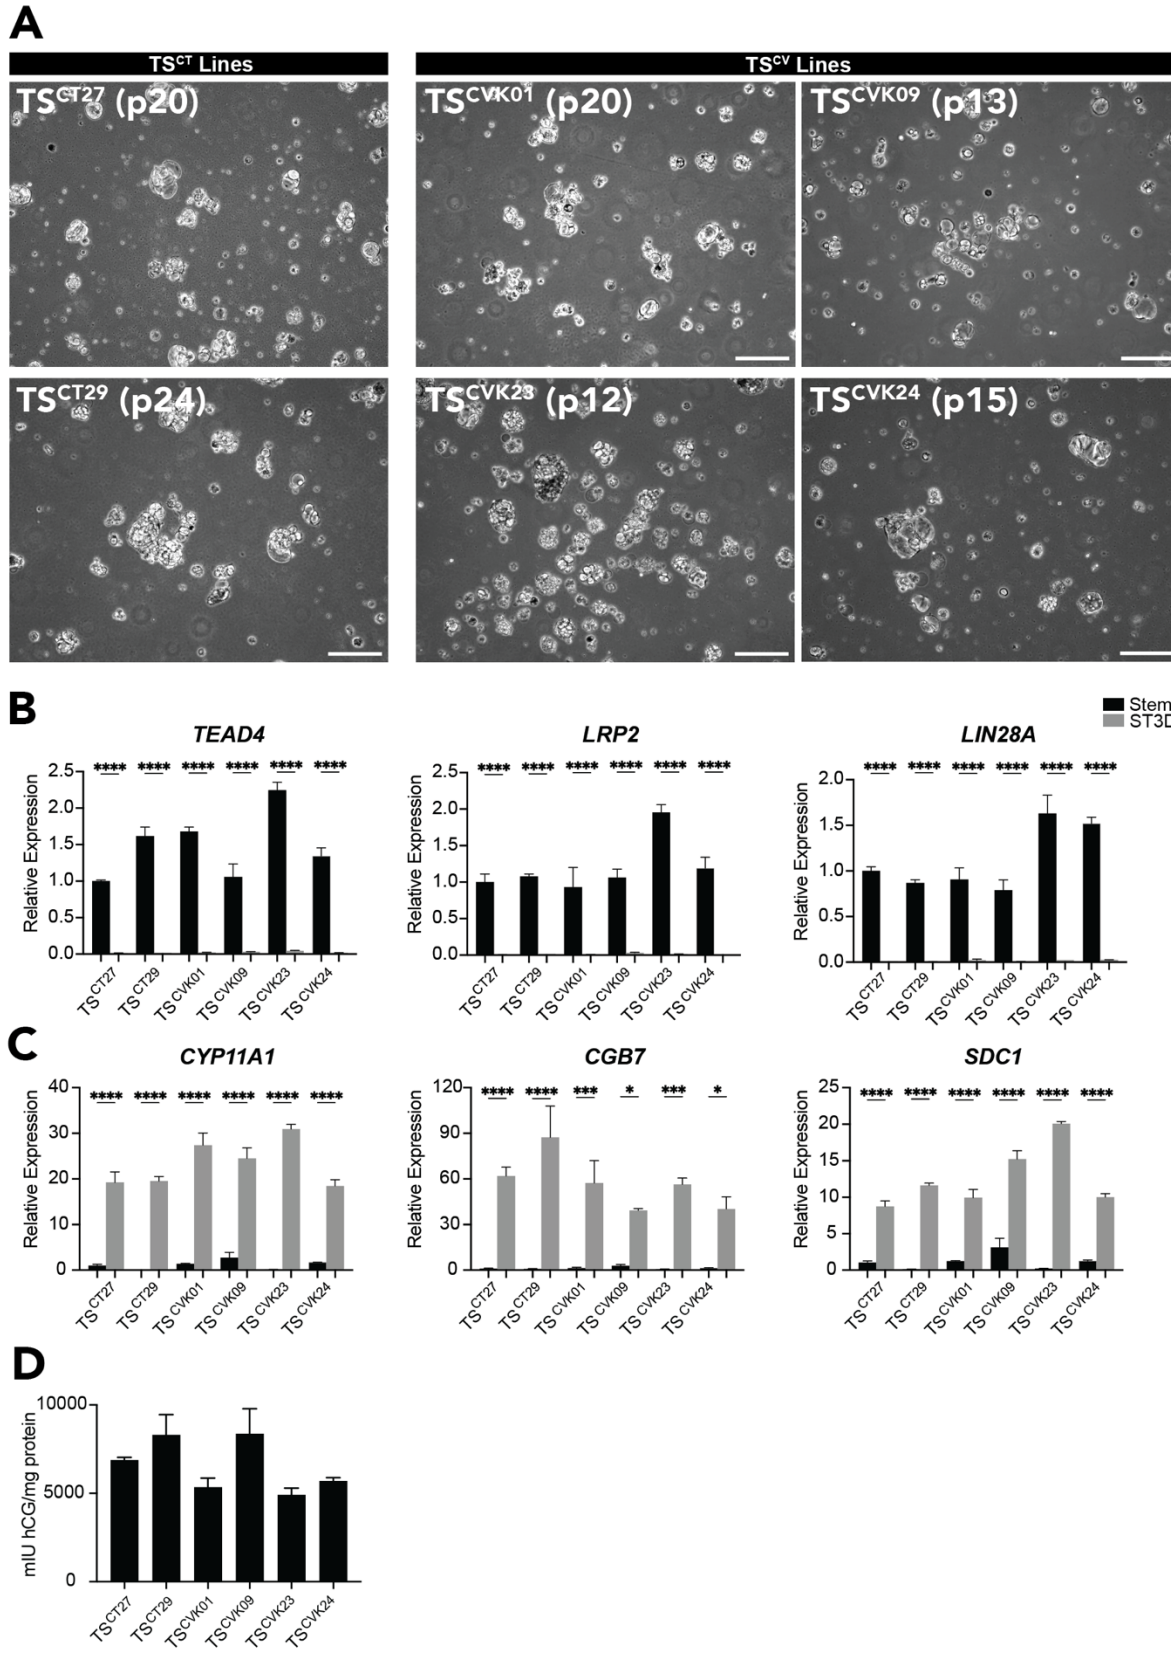

816

817 **Fig. 2 Characterization of TS<sup>CV</sup> cells.** **A)** Stem state phase contrast images of four chorionic  
 818 villus-derived TS cell lines (TS<sup>CVK01</sup>, TS<sup>CVK09</sup>, TS<sup>CVK23</sup>, TS<sup>CVK24</sup>) alongside images of the  
 819 reference cytotrophoblast-derived TS cell lines (TS<sup>CT27</sup> and TS<sup>CT29</sup>) at different passage

820 numbers (13-20). Scale bars represent 500  $\mu\text{m}$ . **B)** Bar graphs depicting expression of three  
821 microRNAs (**miR**) from the C19MC cluster (hsa-miR-517a-3p, has-miR-517-5p, and hsa-miR-  
822 526b-3p) in TS<sup>CT</sup> and TS<sup>CV</sup> cell lines relative to induced pluripotent stem (**iPS**) cells, measured  
823 by RT-qPCR. Data were normalized to the control miRNA, hsa-miR-103a-3p (n=3 samples per  
824 group; \*p<0.05, \*\*p<0.01, \*\*\*p<0.001, \*\*\*\*p<0.0001). **C)** Plots representing DNA methylation  
825 levels in the ELF5 promoter at 11 sites in TS<sup>CT</sup> and TS<sup>CV</sup> cell lines compared to iPS cells.  
826 Methylated sites (black) and unmethylated sites (white) are shown for 10 replicates and the  
827 average percent methylation is listed.

**Fig. 3**

830 **TS<sup>CV</sup> cell line differentiation into STB. A)** Representative phase contrast images of

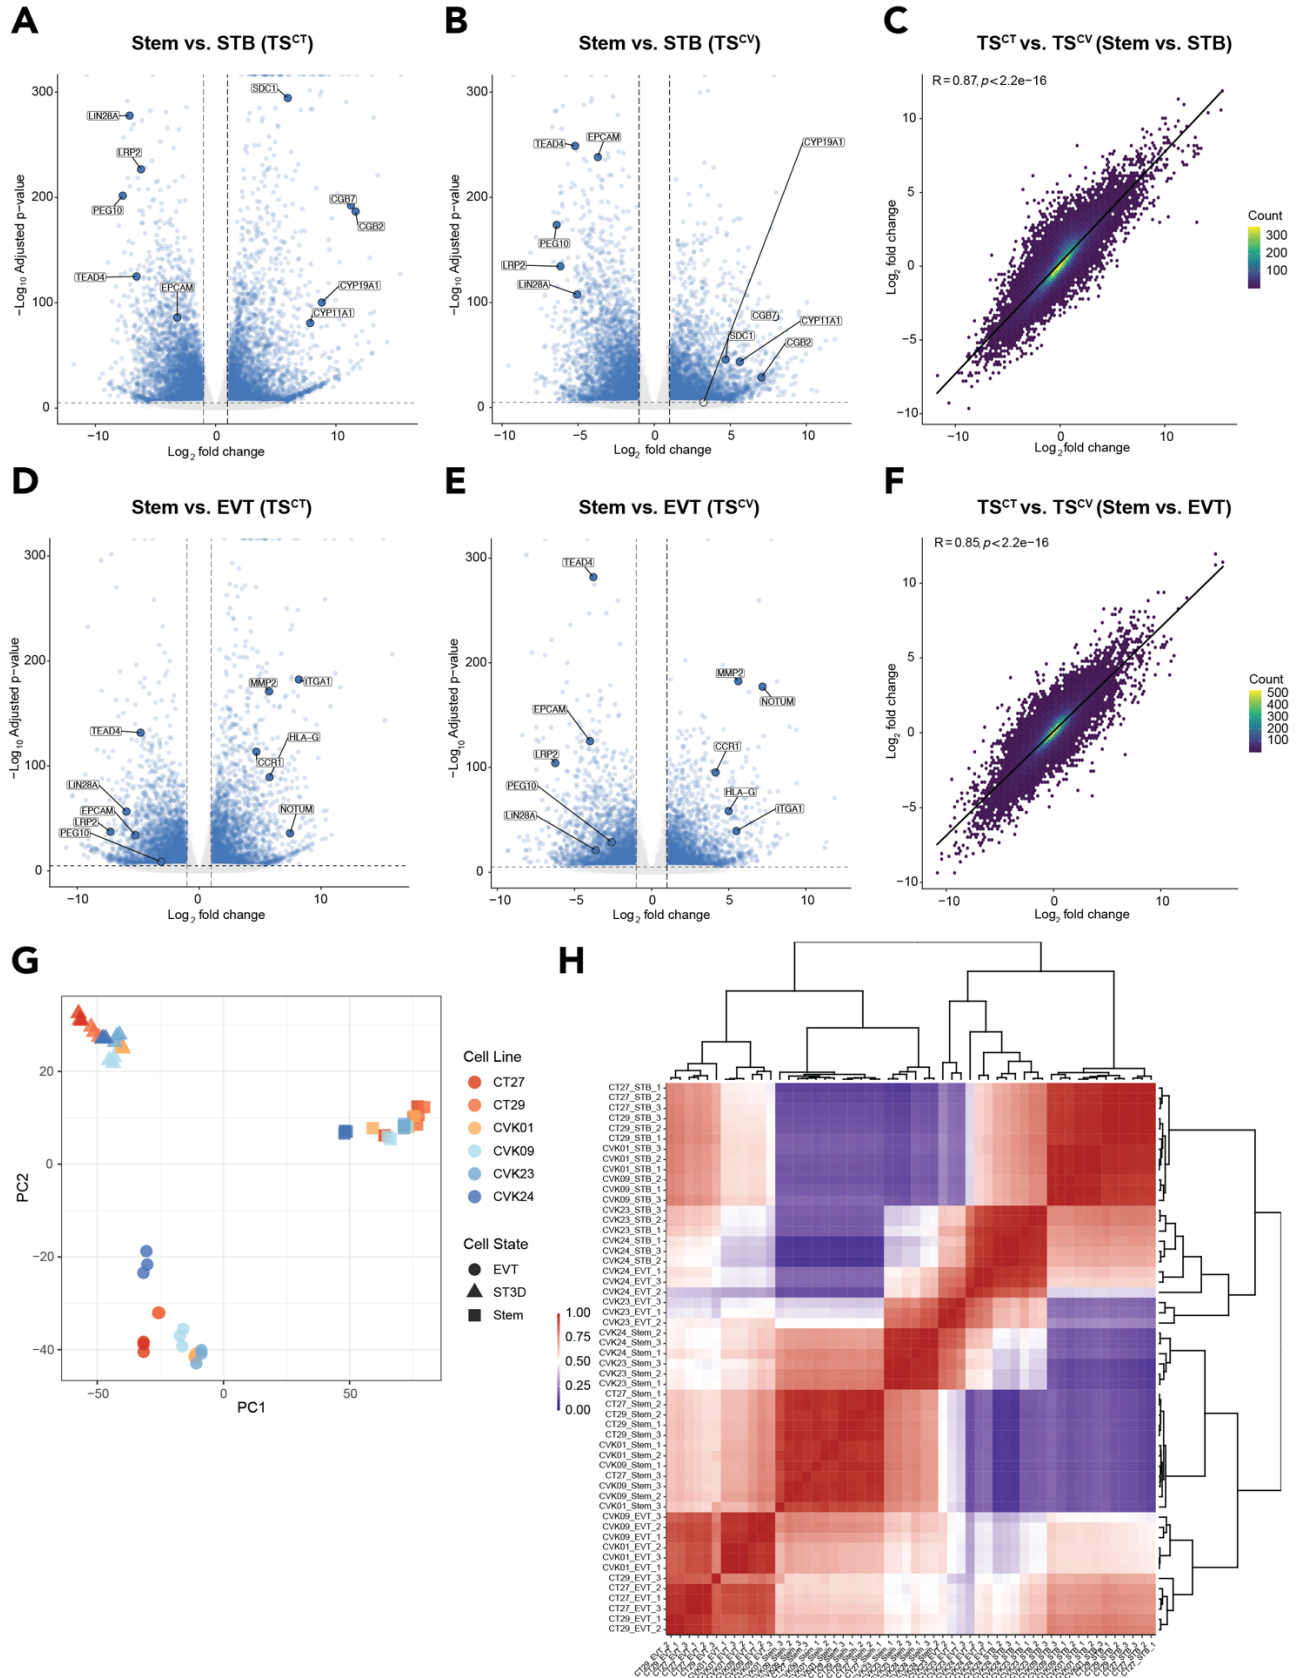

831 cytotrophoblast-derived TS<sup>CT27</sup> and TS<sup>CT29</sup> cells and four chorionic villus-derived TS cell lines  
832 possessing a normal karyotype, TS<sup>CVK01</sup>, TS<sup>CVK09</sup>, TS<sup>CVK23</sup>, and TS<sup>CVK24</sup> cultured under STB  
833 differentiation conditions. Scale bars represent 250  $\mu$ m. **B-C** Stem cell-associated transcripts  
834 (**B**; *TEAD4*, *LRP2*, and *LIN28A*) and STB cell-associated transcripts (**C**; *CYP11A1*, *CGB7*, and  
835 *SDC1*) were quantified by RT-qPCR in stem (black) and STB differentiated (gray) TS<sup>CT27</sup>,  
836 TS<sup>CT29</sup>, TS<sup>CVK01</sup>, TS<sup>CVK09</sup>, TS<sup>CVK23</sup>, and TS<sup>CVK24</sup> cells (n=3 samples per group; \*\*p<0.01,  
837 \*\*\*p<0.001, \*\*\*\*p<0.0001). **D** Chorionic gonadotropin (**CG**) protein levels (mIU/mg protein) were  
838 quantified by ELISA in cell culture supernatants collected from TS<sup>CT</sup> and TS<sup>CV</sup> cultured cells.

839 **Fig. 4** TS<sup>CV</sup> cell line differentiation into EVT cells. **A)** Representative phase contrast images  
 840 of cytotrophoblast-derived TS<sup>CT27</sup> and TS<sup>CT29</sup> cells and four chorionic villus-derived TS cell lines  
 841 possessing a normal karyotype, TS<sup>CVK01</sup>, TS<sup>CVK09</sup>, TS<sup>CVK23</sup>, and TS<sup>CVK24</sup> cells cultured under EVT

842 cell differentiation conditions. Scale bars represent 250  $\mu\text{m}$  **B**) Immunofluorescence detection of  
843 HLA-G (gray) by immunocytochemistry in  $\text{TS}^{\text{CT}}$  and  $\text{TS}^{\text{CV}}$  cells cultured in the stem state and on  
844 day 8 of EVT cell differentiation. DAPI (magenta) stains cell nuclei. Scale bars represent 100  
845  $\mu\text{m}$ . **C-D**) Stem cell-associated transcripts (**C**; *TEAD4*, *LRP2*, and *LIN28A*) and EVT cell-  
846 associated transcripts (**D**; *HLA-G*, *MMP2*, and *CCR1*) were quantified by RT-qPCR in stem  
847 (black) and EVT differentiated (gray)  $\text{TS}^{\text{CT27}}$ ,  $\text{TS}^{\text{CT29}}$ ,  $\text{TS}^{\text{CVK01}}$ ,  $\text{TS}^{\text{CVK09}}$ ,  $\text{TS}^{\text{CVK23}}$ , and  $\text{TS}^{\text{CVK24}}$  cells  
848 (n=3 samples per group; \*p<0.05, \*\*p<0.01, \*\*\*p<0.001, \*\*\*\*p<0.0001).

850 **Fig. 5 TS<sup>CV</sup> and TS<sup>CT</sup> cells cluster by cell state and share similar transcriptomes. A-B)**  
851 Volcano plots depicting significantly up- and down-regulated genes based on transcripts  
852 measured by RNA-seq in stem versus STB state TS<sup>CT</sup> (A) and TS<sup>CV</sup> (B) cells. Gene transcript  
853 levels unchanged between stem and STB state cells are depicted in gray (n=3 per group;  
854 absolute Log<sub>2</sub> fold change >1, adjusted p<0.05). C) Two-dimensional density plot comparing  
855 gene expression changes between stem and STB cell states in TS<sup>CT</sup> (TS<sup>CT27</sup> and TS<sup>CT29</sup>) cells  
856 versus TS<sup>CV</sup> (TS<sup>CVK01</sup>, TS<sup>CVK09</sup>, TS<sup>CVK23</sup>, and TS<sup>CVK24</sup>) cells (Pearson correlation coefficient  
857 (R)=0.87, p<2.2e-16). D-E) Volcano plots depicting significantly up- and down-regulated genes  
858 based on transcripts measured by RNA-seq in stem versus EVT states of TS<sup>CT</sup> (E) and TS<sup>CV</sup> (E)  
859 cells. Gene transcript levels unchanged between stem and EVT state cells are depicted in gray  
860 (n=3 per group; absolute Log<sub>2</sub> fold change >1, adjusted p<0.05). F) Two-dimensional density  
861 plot comparing gene expression changes between stem and EVT cell states in TS<sup>CT</sup> (TS<sup>CT27</sup> and  
862 TS<sup>CT29</sup>) cells versus TS<sup>CV</sup> (TS<sup>CVK01</sup>, TS<sup>CVK09</sup>, TS<sup>CVK23</sup>, and TS<sup>CVK24</sup>) cells (Pearson correlation  
863 coefficient (R)=0.85, p<2.2e-16). G) Principal component analysis based on RNA-seq datasets  
864 generated from TS<sup>CT</sup> and TS<sup>CV</sup> cells cultured in the stem state or following differentiation into  
865 STB and EVT cell lineages. H) Heat map showing scaled normalized read counts representing  
866 gene expression profiles of stem state, STB, and EVT differentiated cells across TS<sup>CT</sup> and TS<sup>CV</sup>  
867 cell lines.

868 **Video Legends**

869

870 **Video 1. Stem state and EVT-differentiated TS<sup>CT27</sup> cell growth and motility.** Phase contrast  
871 images were acquired every 10 min for 53 h of TS<sup>CT27</sup> cells cultured under stem state or EVT  
872 cell-differentiation conditions (EVT cell differentiation protocol days 4-6).

873

874 **Video 2. Stem state and EVT cell differentiated TS<sup>CVK01</sup> cell growth and motility.** Phase  
875 contrast images were acquired every 10 min for 53 h of TS<sup>CVK01</sup> cells cultured under stem state  
876 or EVT cell differentiation conditions (EVT cell differentiation protocol days 4-6).

877

878 **Video 3. Stem state and EVT cell differentiated TS<sup>CVK09</sup> cell growth and motility.** Phase  
879 contrast images were acquired every 10 min for 53 h of TS<sup>CVK09</sup> cells cultured under stem state  
880 or EVT cell differentiation conditions (EVT cell differentiation protocol days 4-6).
