34 ABSTRACT

35 Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by autoantibodies  
36 raised against nuclear antigens and whose production is promoted by autoreactive T follicular helper  
37 (TFH) cells. Basophils, by accumulating in secondary lymphoid organs (SLO), amplify autoantibody  
38 production and disease progression through mechanisms to be defined. Here, we demonstrate that a  
39 functional relationship between TFH cells and basophils occurs in SLO during lupus pathogenesis. On  
40 SLE patient blood basophils, PD-L1 expression was upregulated and associated with TFH and TFH2  
41 cell expansions and with disease activity. In two distinct lupus-like mouse models, TFH cell  
42 pathogenic accumulation, maintenance and function, and disease activity were dependent on  
43 basophils and their expressions of PD-L1 and IL-4. Our study establishes a direct link between  
44 basophils and TFH cells in the SLE context that promotes autoreactive IgG production and lupus  
45 nephritis pathogenesis. Altering the basophil/TFH cell axis in the SLE context may represent a  
46 promising innovative intervention strategy in SLE.

52

## 53 INTRODUCTION

54 Systemic lupus erythematosus (SLE) is a multifactorial autoimmune disease that can affect different  
55 organs including joints, skin, or kidneys (lupus nephritis). A break in tolerance to nuclear self-antigens  
56 leads to an accumulation of autoreactive B and T cells in SLE patients that drives the production of  
57 autoreactive antibodies mainly raised against nuclear antigens, such as double-stranded DNA  
58 (dsDNA) or ribonucleoproteins (RNP). These autoantibodies form circulating immune complexes (CIC)  
59 after aggregation to complement factors and autoantigens. CIC deposit in target organs where they  
60 can induce a chronic inflammation leading to tissue damage and organ dysfunction. In parallel, CIC  
61 activate innate immune cells such as plasmacytoid dendritic cells, monocytes/macrophages,  
62 neutrophils, and basophils that enhance autoantibody production through the release of various  
63 inflammatory mediators and initiate a deleterious amplification loop of the disease<sup>1,2</sup>.

64 Autoantibody production is a key event in lupus pathogenesis. Its disruption represents an intensive  
65 area of clinical development of biotherapies targeting directly the B cells or pathways promoting  
66 their survival and maturation<sup>3</sup>. Recent advances in the understanding of SLE pathogenesis have shed  
67 some light on the role of T follicular helper CD4<sup>+</sup> (TFH) cells. TFH cells are central for follicular B cell  
68 maturation into antibody-secreting cells and their numbers and functions are dysregulated in both  
69 human SLE patients and some lupus-like murine models<sup>4-8</sup>. TFH cells are characterized by their  
70 expression of the transcription factor BCL6 and their surface expression of C-X-C motif chemokine  
71 receptor 5 (CXCR5) which allows their localization into the germinal centers to provide B cell help  
72 through IL-21 production and promote the maturation of antibody-secreting cells<sup>7</sup>. TFH cells express  
73 programmed cell-death 1 receptor (PD-1) that is essential for their positioning, functions, and  
74 regulation in secondary lymphoid organs (SLO)<sup>9</sup>. GATA-3 transcription factor expression, IL-4  
75 production, and potent help provided to B cells characterize the TFH type 2 (TFH2) cell subset that is  
76 overrepresented in the lupus context and associated with disease activity<sup>6</sup>.

77 Basophils are activated during SLE pathogenesis and accumulate in SLO where they promote  
78 autoantibody production by supporting antibody-secreting plasmablast accumulation<sup>10,11</sup>. Depleting  
79 basophils in lupus-like mouse models with established disease dampens lupus-like activity by  
80 reducing plasmablast numbers, autoantibody titers, CIC deposits in glomeruli, and kidney  
81 inflammation<sup>10,11</sup>, thus demonstrating that basophils are responsible for an amplification loop driving  
82 the disease to a pathogenic threshold. In agreement, constitutive basophil deficiency prevents lupus-  
83 like disease onset in the pristane-induced lupus-like disease model<sup>12</sup>. In this context, targeting the  
84 addressing of basophils to SLO has demonstrated promising therapeutic potential<sup>11,13</sup>. In the *Lyn*<sup>-/-</sup>  
85 lupus-like mouse model, we previously showed that basophils accumulate in SLO where they express  
86 surface molecules that suggest interactions with the B and T cell compartments to promote plasma  
87 cell maturation and antibody secretion<sup>10</sup>. However, the mechanisms by which basophils, once in SLO,  
88 actually promote this disease amplification loop remains unknown.

89 Here, we screened cell surface molecules on blood basophils from SLE patients that could support a  
90 functional interaction of these cells with SLO cell partners in the lupus context. We demonstrate *in*  
91 *vitro* in humans and *in vivo* in two different SLE mouse models that PD-L1 expression and IL-4  
92 production by basophils are required to promote the cross-talk of these cells with TFH cells to sustain  
93 TFH cell pathogenic accumulation, TFH2 cell differentiation, and thereby mediate SLE disease onset  
94 and progression.

## 95 RESULTS

### 96 Human blood basophils from SLE patients overexpress PD-L1

97 TFH, and especially TFH2, cells are significant contributors to the pathophysiology of SLE. Proportions  
98 among CD4<sup>+</sup> T cells of circulating TFH (cTFH) and cTFH2 cells are increased in several SLE patient  
99 cohorts and lupus-like mouse models<sup>4-7,14,15</sup>. We first assessed these cTFH cells (CD3<sup>+</sup> CD4<sup>+</sup> CXCR5<sup>+</sup>  
100 ICOS<sup>+</sup> PD-1<sup>+</sup> cells) and cTFH2 cells (CCR6<sup>-</sup> CXCR3<sup>-</sup> TFH cells) in our SLE patient cohort (**Table S1**) and  
101 confirmed both their increased representation among CD4<sup>+</sup> T cells and a cTFH2 cell bias that was  
102 associated with disease activity (**Fig. 1a-c**).

103 We and others reported that peripheral basopenia and activation of blood basophils correlate with  
104 disease activity in SLE patients<sup>10,11,16</sup>. Our current SLE patient cohort further confirmed this blood  
105 basophil phenotype as evidenced by basopenia and overexpression of the activation marker CD203c,  
106 the chemokine receptor CXCR4, and the L-selectin CD62L, all of them being associated with disease  
107 activity (**Fig. S1a-e** and **Fig. 1d**).

108 To investigate whether, in the SLE context, human basophils were more prone to interact with TFH  
109 cells, we assessed the expression levels of several surface markers identified to be relevant  
110 interacting molecules with TFH cells. PD-L2, ICOSL, and OX40L were barely detected on the surface of  
111 human blood basophils and no difference in their expression levels on basophils from healthy donors  
112 or SLE patients was observed (**Table S2**). Nevertheless, PD-L1 was strongly upregulated on the  
113 surface of SLE patient blood basophils as compared to healthy donor blood basophils, independently  
114 of the activity of the disease (**Fig. 1e** and **Table S2**). In addition, PD-L1 expression on SLE patient  
115 blood basophils correlated with the basophil activation status (Spearman  $r=0.3113$ ,  $P < 0.0001$ ,  
116  $n=204$ ) (**Fig. S1f**). CD84, a member of the SLAM family of proteins important for TFH cell regulation<sup>17</sup>,  
117 was highly expressed by human basophils (**Fig. S1g** and **Table S2**). Although no significant increase in  
118 CD84 expression on blood basophils from the whole SLE patient cohort was found, its expression was

119 significantly increased on blood basophils from active SLE patients as compared to healthy volunteers  
120 (**Fig. S1g** and **Table S2**).

121 Altogether, these results demonstrated that basophils from SLE patients overexpress PD-L1 and  
122 CD84, suggesting that a basophil-TFH cell interaction may occur during lupus pathogenesis.

### 123 **Basophil-TFH cell axis in lupus-like mouse models**

124 We next sought to verify whether this increased expression of PD-L1 on basophils from SLE patients  
125 was also detected on basophils from lupus-like mouse models in which basophil contribution to  
126 disease activity is established<sup>10,11,18</sup>. PD-L1 expression was increased on the surface of basophils from  
127 both pristane-induced and *Lyn*<sup>-/-</sup> lupus-like mouse models in the analyzed compartments (blood,  
128 spleen, and lymph nodes) (**Fig. 2a,b**). As shown in other human studies and previous reports<sup>7,11</sup>,  
129 increased TFH cell proportions among CD4<sup>+</sup> T cells and basophil accumulation were observed in both  
130 lupus-like mouse models in blood and the secondary lymphoid organs spleen, and lymph nodes (**Fig.**  
131 **2c-f** and **Fig. S2**). These results suggest a positive correlation between basophils and TFH cells during  
132 lupus-like disease.

133 To evaluate whether a functional relationship between basophils and TFH cells was taking place  
134 during the course of the disease, we depleted basophils through diphtheria toxin injection in  
135 *Mcpt8*<sup>DTR</sup> mice in both lupus-like models during ten days before their analysis (**Fig. S2a,b**). We  
136 previously showed that basophil depletion dampens CD19<sup>+</sup>CD138<sup>+</sup> short-lived plasma cell numbers in  
137 SLO, autoantibody titers, kidney deposits and inflammation, and disease activity in these  
138 models<sup>10,11,18</sup>. Here, in agreement, efficient DT-mediated basophil depletion (**Fig. 2e,f** and **Fig. S2a,b**)  
139 resulted in a dramatic decrease in autoreactive IgG antibody titers in both pristane-induced and *Lyn*<sup>-/-</sup>  
140 *Lyn*<sup>-/-</sup> lupus-like mouse models (**Fig. 2g,h**). In addition, it abrogated the increase in TFH cell proportions in  
141 blood and SLO from lupus-like mice (**Fig. 2c,d** and **Fig. S2c,d**), strongly suggesting a functional  
142 relationship between the two cell compartments. Of note, basophil depletion in *Lyn*<sup>-/-</sup> *Mcpt8*<sup>DTR</sup> mice

143 did not modify the proportion of regulatory TFH (TFR) cells among the TFH cell population (**Fig.**  
144 **S3a,b**).

145 We recently showed that basophils play a nonredundant role in pristane-induced lupus-like disease  
146 and that basophil-deficient mice (*Mcpt8<sup>CT/+</sup> Rosa26<sup>DTA/+</sup>* mice) are resistant to pristane-induced lupus-  
147 like disease onset<sup>12</sup>. The functional relationship between basophils and TFH cells was further  
148 confirmed in this mouse model since no increase in the TFH cell proportion was observed in pristane-  
149 injected basophil-deficient mice as compared to control mice (*Mcpt8<sup>CT/CT</sup> Rosa26<sup>+/+</sup>*) in any of the  
150 analyzed compartments (**Fig. 2i**).

151 The functional interaction between the two cell types seemed restricted to the lupus-like  
152 environment. Indeed, basophil depletion in WT animals in both models or constitutive basophil  
153 deficiency did not modify the basal proportions of TFH cells in the observed compartments (**Fig.**  
154 **2c,d,i**). Moreover, basophils, which are not involved in the humoral response to the ovalbumin (OVA)  
155 protein after intraperitoneal immunization in alum<sup>19</sup>, did not influence the rise in TFH cell numbers in  
156 these conditions. Indeed, we could measure the induction of TFH cells in OVA-immunized mice which  
157 was associated with the production of anti-OVA IgG antibodies but not with the accumulation of  
158 basophils in the spleen nor in the draining (mesenteric) lymph node (**Fig. S3c-f**). DT-mediated  
159 basophil depletion starting the last 48 hours of the immunization procedure did not modify the TFH  
160 cell response nor the anti-OVA IgG titers in immunized mice, suggesting that basophils were not  
161 involved in the support of TFH cells in a protein-immunization setting, unlike what we observed in  
162 the lupus-like context (**Fig. S3c-f** and **Fig. 2**).

163 Altogether, these data strongly suggest that basophils, by accumulating in SLO, enable the expansion  
164 of the TFH cell population in two distinct lupus-like mouse models and that basophils and TFH cells  
165 may share a functional relationship in the lupus-like context.

166 **Basophils control TFH cell ability to produce IL-21 and IL-4 in a lupus-like context**

167 We next assessed whether basophils could influence the cytokine production abilities of the  
168 expanded TFH cells during the disease. First, the proportions of spleen TFH cells producing IL-21  
169 without any restimulation were significantly increased in both lupus-like models and further  
170 amplified after phorbol myristate acetate (PMA) and ionomycin restimulation as compared to spleen  
171 TFH cells from control mice (**Fig. 3a-c**). This suggested that in the lupus-like context, TFH cells are  
172 more prone to provide IL-21 to surrounding cells in these mouse models. Second, the same  
173 observations were done concerning IL-4 production by TFH cells showing a TFH2 bias in these two  
174 lupus-like models (**Fig. 3d-f**), as was also observed in the SLE patient cohort (**Fig. 1c**). Of note, no such  
175 bias was observed for IFN $\gamma$  production by TFH cells in any of the mouse models (**Fig. 3g,h**). Third,  
176 basophil depletion dramatically dampened both constitutive and PMA-ionomycin-induced IL-21 and  
177 IL-4 productions by TFH cells only in the lupus-like context, without significantly influencing their IFN $\gamma$   
178 production ability (**Fig. 3a-h**). These results strongly suggest that, in the lupus-like context, basophils  
179 promoted TFH cell-derived IL-21 and IL-4 production ability and were responsible for a TFH2 cell bias  
180 of this T cell population.

181 Both IL-6 and IL-4 are involved, respectively, in TFH and TFH2 cell differentiation<sup>7,15</sup>. Basophils are  
182 potent producers of these cytokines<sup>20,21</sup>. We next assessed whether basophils in both pristane-  
183 injected and Lyn-deficient animals were more prone to produce these cytokines with or without  
184 PMA-ionomycin restimulation. Unlike what was observed in basophils from control mice, constitutive  
185 IL-4 and IL-6 productions were significantly detected in non-restimulated basophils from both lupus-  
186 like models, whereas no major differences were noticed after PMA-ionomycin restimulation (**Fig. 3i-**  
187 **m**). These results suggested that during the course of the disease, along with their increased  
188 expression of PD-L1 (**Fig. 2a,b**), basophils produce IL-6 and IL-4 *in vivo* which may explain some of  
189 their effects on the expansion of the TFH cell population and its TFH2 cell bias.

190 **Basophils promote *ex vivo* TFH cell differentiation through IL-4- and PD-L1-dependent mechanisms**

191 Next, we evaluated the effects of basophils and basophil-expressed mediators on the differentiation  
192 of TFH cells *ex vivo* in a co-culture system. The presence of basophils induced a clear differentiation  
193 of the CD3/CD28-activated naïve CD4<sup>+</sup> T cells towards the TFH cell subset with an increased ability of  
194 these TFH cells to produce IL-21 and IL-6 (Fig. 4a-c). Moreover, the basophil-induced TFH cell  
195 differentiation was biased towards the TFH2 cell subset as evidenced by an increased ability to  
196 produce IL-4 and IL-13 (Fig. 4d,e). We next bred CT-M8 (or *Mcpt8<sup>CT/CT</sup>*) mice<sup>12</sup> with *Il4<sup>fl/fl</sup>*<sup>22</sup>, *Il6<sup>fl/fl</sup>*<sup>23</sup>, or  
197 *Pdl1<sup>fl/fl</sup>*<sup>24</sup> mice and generated mice deficient for IL-4, IL-6, or PD-L1 selectively in the basophil  
198 compartment (Fig. S4a-c). IL-4-deficient basophils could not induce any of the effects on the TFH cell  
199 differentiation as compared to WT basophils (Fig. 4a-e). IL-6-deficient basophils could still induce TFH  
200 cell differentiation despite reduced IL-6, but increased IL-21, production by TFH cells (Fig. 4a-c) and  
201 had a limited effect on the TFH2 cell differentiation (Fig. 4d,e). Interestingly, PD-L1 expression by  
202 basophils was mandatory to induce TFH cell differentiation but had a limited impact on the TFH2 cell  
203 differentiation that was completely dependent on basophil-expressed IL-4 (Fig. 4a-e). Of note, PMA-  
204 ionomycin restimulation of the co-cultured cells in the aforementioned conditions led to the same  
205 conclusions (Fig. S4d-g).

206 Altogether, these results demonstrated that basophils induce *ex vivo* TFH cell differentiation in an IL-  
207 4- and PD-L1-dependent manner and that basophil-derived IL-6 is dispensable for these effects.

#### 208 **CD4<sup>+</sup> T cells promote basophil ability to induce TFH cell differentiation *ex vivo***

209 In parallel, we analyzed the effects of the CD4<sup>+</sup> T cells on the basophil compartment. The presence of  
210 CD4<sup>+</sup> T cells up-regulated PD-L1 expression on basophils and induced constitutive IL-4, IL-6, and IL-13  
211 productions by these cells (Fig. 4f-k). The CD4<sup>+</sup> T cell-induced up-regulation of PD-L1 on basophils  
212 was partially dependent on the IL-4 produced by basophils themselves, but independent of basophil-  
213 derived IL-6 (Fig. 4f,g). Conversely, the CD4<sup>+</sup> T cell-induced IL-4 (and IL-6) production by basophils  
214 was partially dependent on PD-L1 expressed by basophils without impacting their maximal  
215 production ability (Fig. 4h-i, and Fig. S4h,i). IL-6 deficiency in basophils did not alter their ability to

216 produce IL-4 constitutively in the presence of CD4<sup>+</sup> T cells nor after PMA-ionomycin restimulation but  
217 enhanced their IL-13 production only in the former situation (**Fig. 4h-k** and **Fig. S4h-j**). These results  
218 suggest that PD-L1 engagement on basophils by CD4<sup>+</sup> T cells, beyond promoting IL-21 production by  
219 TFH cells (**Fig. 4b**), was responsible for the extent of T cell-induced cytokine production by basophils.  
220 This may explain why PD-L1 deficient basophils could not promote TFH cell differentiation (**Fig. 4a**).  
221 Of note, CD4<sup>+</sup> T cells induced IL-13 production by basophils and enhanced their maximal ability to  
222 produce this cytokine independently of their IL-4 or PD-L1 expression (**Fig. 4k** and **Fig. S4j**).

223 Altogether, these results strongly suggest that a bi-directional interaction between naïve CD4<sup>+</sup> T cells  
224 and basophils leads to the differentiation of TFH cells via a mechanism mainly depending on IL-4 and  
225 PD-L1 expression by basophils but independent of the basophil-derived IL-6.

#### 226 **PD-L1 controls the basophil-TFH cell functional relationship during lupus-like disease**

227 We next sought to validate *in vivo* the relevance of PD-L1 expression by basophils in their functional  
228 relationship with TFH cells in the lupus-like context. Pristane injection did not lead to TFH cell  
229 accumulation in SLO in mice with basophil-restricted PD-L1-deficiency (*Mcpt8<sup>CT/+</sup> Pdl1<sup>f/f</sup>*) as  
230 compared to WT animals (*Mcpt8<sup>CT/+</sup>*) (**Fig. 5a** and **Fig. S5**). However, PD-L1 expression by basophils  
231 was not required for basophil accumulation in SLO (**Fig. 5b**). Both the lupus-like context *in vivo* (**Fig.**  
232 **3l,m**) and the co-culture system *in vitro* (**Fig. 4h-k**) induced IL-4 and IL-6 production by basophils.  
233 Here, PD-L1 deficiency on basophils completely prevented these cytokine basal productions in the  
234 lupus-like context (**Fig. 5c,d**). This was associated with a non-expansion of CD19<sup>+</sup>CD138<sup>+</sup> cells in SLO  
235 (**Fig. 5e**) leading to dramatically reduced anti-RNP autoreactive IgG titers in the blood (**Fig. 5f**).  
236 Moreover, increased IgG and C3 glomerular deposits were barely detectable in the kidney of  
237 pristane-injected *Mcpt8<sup>CT/+</sup> Pdl1<sup>f/f</sup>* mice as compared to their WT counterparts (**Fig. 5g,h**).

238 Altogether, these results strongly suggest that PD-L1 basophil expression and up-regulation during  
239 lupus development were not involved in basophil accumulation in SLO but were responsible for the

240 basophil-induced promotion of TFH and short-lived plasma cell expansions and subsequent  
241 pathological parameters.

## 242 **Basophil-derived IL-4 exerts a dual effect during lupus-like disease development**

243 Since TFH cell differentiation *ex vivo* depended on IL-4 expression by basophils (**Fig. 4**), we next  
244 sought to verify whether basophil-derived IL-4 was mandatory for the basophil-TFH cell functional  
245 relationship in the lupus-like context. As suggested above, IL-4 deficiency selectively in the basophil  
246 compartment (*Mcpt8<sup>CT/+</sup> Il4<sup>fl/fl</sup>*) prevented the pristane-induced TFH cell accumulation in SLO as  
247 compared to WT (*Mcpt8<sup>CT/+</sup>*) animals (**Fig. 6a**). By contrast, basophil recruitment into SLO upon  
248 pristane treatment of the mice was not dependent on basophil-derived IL-4 since basophil  
249 accumulation in these locations in mice was similar in *Mcpt8<sup>CT/+</sup> Il4<sup>fl/fl</sup>* and *Mcpt8<sup>CT/+</sup>* WT animals (**Fig.**  
250 **6b**). Surprisingly, CD19<sup>+</sup>CD138<sup>+</sup> cells still accumulated in SLO despite selective basophil IL-4 deficiency  
251 (**Fig. 6c**). This phenotype was associated with a still significant constitutive IL-6 production by IL-4-  
252 deficient basophils in the lupus-like context (**Fig. 6d**). However, no significant titers of anti-RNP IgG  
253 autoantibodies were detected in the blood of pristane-injected *Mcpt8<sup>CT/+</sup> Il4<sup>fl/fl</sup>* mice as compared to  
254 their WT counterparts. In line with this feature, no IgG deposits were present in the glomeruli of  
255 pristane-treated mice with basophil-specific IL-4 deficiency but C3 deposits, although reduced, were  
256 still detected (**Fig. 6f** and **Fig. S6a,b**). Along with the accumulation of CD19<sup>+</sup>CD138<sup>+</sup> cells in the SLO,  
257 the latter result led us to assess the presence of autoreactive IgM in the pristane-treated *Mcpt8<sup>CT/+</sup>*  
258 *Il4<sup>fl/fl</sup>* mice. As suspected, increased titers of anti-RNP IgM in the plasma of mice with IL-4 deficient  
259 basophils were observed as compared to pristane-treated *Mcpt8<sup>CT/+</sup>* WT mice (**Fig. 6g**). These  
260 autoreactive IgM were not detected in the blood from pristane-injected basophil-specific PD-L1-  
261 deficient mice nor constitutive basophil-deficient mice (**Fig. 6g**) in line with the absence of  
262 plasmablast accumulation in SLO from these mice (**Fig. 5e** and <sup>12</sup>). These anti-RNP IgM titers  
263 correlated with the presence of IgM deposits in the glomeruli of the corresponding mice (**Fig. 6h,i**).

264 Altogether, these results strongly suggest that TFH cell pathogenic accumulation in SLO and  
265 autoreactive IgG titers induced by pristane were dependent on the basophil-derived IL-4. However,  
266 CD19<sup>+</sup>CD138<sup>+</sup> short-lived plasma cell accumulation, which is dependent on basophils (**Fig. 2** and  
267 <sup>11,12,18</sup>), was not dependent on IL-4 production by basophils. This led to an accumulation of plasmatic  
268 autoreactive anti-RNP IgM, with no IgG deposits but increased C3 deposits in glomeruli of the  
269 *Mcpt8<sup>CT/+</sup> Il4<sup>fl/fl</sup>* mice, suggesting that basophil-derived IL-4 was both enabling autoreactive antibody  
270 switch towards the IgG isotype and TFH cell accumulation that promoted this phenomenon as  
271 well<sup>7,15</sup>.

### 272 **Human basophils drive *ex vivo* TFH cell and TFH2 cell differentiation through IL-4, IL-6, and PD-1-** 273 **dependent mechanisms**

274 We next sought to validate the ability of basophils to promote TFH cell differentiation in a human co-  
275 culture system. First, CD3- and CD28-activated human naïve CD4<sup>+</sup> T cells were cultured for three days  
276 without or with increasing numbers of purified human basophils demonstrating the capacity of  
277 human blood basophils to induce TFH cell differentiation (**Fig. 7a-c**) more potently than mouse  
278 spleen basophils (**Fig. 4a**). Next, cultures of CD3- and CD28-activated human naïve CD4<sup>+</sup> T cells alone  
279 or together with basophils were repeated in the presence of blocking antibodies targeting IL-4, IL-6,  
280 PD-1, or their corresponding isotype controls. As seen in the murine system, IL-4 and PD-1  
281 antagonisms led to a dramatic decrease in the ability of human basophils to drive CD4<sup>+</sup> T cell  
282 differentiation into TFH cells (**Fig. 7d**). IL-6 blockade also decreased basophil-induced TFH cell  
283 differentiation, probably due to its effects on the T cell-derived IL-6 (**Fig. 7d**). Most of the basophil-  
284 induced TFH cells were belonging to the TFH2 cell subset expressing neither CCR6 nor CXCR3 (**Fig.**  
285 **7e,f**). This TFH2 cell subset differentiation was dramatically dampened by the blockade of IL-4, IL-6,  
286 or PD-1 (**Fig. 7e,f**).

287 Altogether, these data demonstrate that human basophils could induce human naïve CD4<sup>+</sup> T cell  
288 differentiation into TFH cells, especially into the TFH2 cell subset, and that this was dependent on IL-

289 4 and PD-1. Together with the PD-L1 overexpression by blood basophils from SLE patients (**Fig. 1e**),  
290 these results strongly suggest that, as demonstrated in the lupus-like mouse models (**Figs. 2-6**),  
291 basophils promote the pathogenic accumulation of TFH cells during SLE pathogenesis through their  
292 expression of PD-L1 and IL-4.

## 293 **DISCUSSION**

294 In this study, we have identified mechanisms by which basophils control the pathogenic  
295 accumulation of TFH cells in SLO to promote autoreactive IgG production during SLE pathogenesis.

296 In a normal antigen-driven immunization process, germinal centers (GC) are key structures that allow  
297 B cell maturation into high affinity and class-switched antibody-secreting cells<sup>25</sup>. The formation and  
298 maintenance of these structures depend on TFH cells<sup>7</sup>. Basophils are dispensable to mount an  
299 efficient humoral response to OVA protein immunization<sup>19</sup> and do not control basal TFH or OVA-  
300 induced TFH cell populations (this study). Importantly, in the latter conditions, basophils do not  
301 accumulate in SLO in contrast to the lupus-like context. Dysregulated expansion of TFH cells in an  
302 SLE-like context occurs through spontaneous GC-like reactions which are favored by the abnormal  
303 cytokine milieu and mainly in the extrafollicular (EF) area<sup>7</sup>. Our results indicate that the pathogenic  
304 accumulation of TFH cells in SLO in a lupus-like context, and thus spontaneous TFH cell responses, are  
305 fully dependent on SLO-localized basophils and more precisely mediated by basophil expression of  
306 PD-L1 and IL-4.

307 The impairment of this basophil-dependent pathogenic accumulation of TFH cell in SLO led to a  
308 dramatic reduction in autoreactive anti-RNP IgG production and IgG kidney deposits, further  
309 validating the relevance of both cell types in autoantibody and pathogenic CIC productions in a lupus-  
310 like context. Investigating whether basophils control spontaneous EF TFH cell responses in other  
311 autoimmune diseases such as rheumatoid arthritis or multiple sclerosis may lead to developing  
312 common therapeutic strategies for these different autoimmune conditions that may share some  
313 pathophysiological pathways<sup>26</sup>.

314 Recently, Kim *et al.* showed that TFH2 cells are induced by, and produce some, IL-4. These TFH2 cells  
315 are central in humoral autoimmunity, promote autoreactive IgE production with their frequencies  
316 increased in both SLE patients and also some SLE-like mouse models<sup>15</sup>. Accordingly, systemic IL-4  
317 blockade dampened TFH2 cell accumulation and their deleterious effects in the *Ets1<sup>ΔCD4</sup>* lupus-like

318 mouse model. As exogenous IL-4 induces Gata3 expression in T cells enabling TH2 cell  
319 differentiation<sup>27</sup>, exogenous IL-4 enabled Gata3<sup>+</sup> TFH2 cell accumulation in an SLE-like context in a  
320 similar way<sup>15</sup>. Our data strongly suggest that basophils deliver the required IL-4-induced priming to  
321 CD4<sup>+</sup> T cells in a PD-L1-dependent manner that allows TFH and TFH2 cell accumulation in the lupus-  
322 like context. Further studies will be required to validate this feature in other lupus-like mouse models  
323 including *Ets1*<sup>ΔCD4</sup> mice. This IL-4 mediated basophil-TFH pathogenic axis is important since basophil  
324 depletion may represent a safer therapeutic strategy than global IL-4 neutralization. Indeed, this  
325 cytokine controls a large number of physiologically protective processes<sup>28,29</sup> and other deleterious  
326 pathways involved in SLE pathophysiology may limit the benefits for the patients of long-term IL-4  
327 blockade<sup>2</sup>.

328 Both human and murine basophils promoted CD3/CD28 activated naïve CD4<sup>+</sup> T cell differentiation  
329 into TFH cells *ex vivo* in the absence of specific antigen or recognized potent antigen-presenting cells.  
330 These effects depended on basophil-expressed IL-4 and PD-L1 (but not on IL-6) for murine cells and  
331 were dampened by IL-4, IL-6, or PD-1 blocking antibodies for human cells. This setting may resume  
332 spontaneous TFH cell responses occurring in the SLE context<sup>7</sup>. TCR repertoire analysis of these  
333 basophil-induced TFH cells may help to decipher whether these spontaneous TFH cell responses  
334 favor autoreactivity of the TFH cell compartment.

335 pDC and type I IFN have recently been shown to promote EF T-dependent B cell responses to  
336 extracellular self DNA<sup>30</sup>. Our data suggest that basophils and their PD-L1 expression are mandatory to  
337 induce TFH cell pathogenic accumulation and B cell response to nuclear antigens. PD-L1 expression  
338 by CD11c-expressing cells inhibits TFH cell response in experimental autoimmune  
339 encephalomyelitis<sup>31</sup>. Type I IFN promotes human basophil apoptosis, but this effect is rescued by IL-  
340 3<sup>32</sup> whose production (mainly by T cells<sup>33</sup>) is increased during SLE pathogenesis<sup>34,35</sup> and acts as well  
341 on pDC survival<sup>36</sup>. Thus, it may be relevant to study the interplay between basophils and DC subsets  
342 in this process. pDC or follicular DC and basophils may indeed compete to engage PD-1 on TFH cells

343 to respectively inhibit or promote TFH cell expansion and TFH2 cell differentiation in EF responses in  
344 an autoimmune context.

345 PD-L1 expression by basophils is known in humans and may be induced by IFN $\gamma$ <sup>37</sup>. PD-L1 upregulation  
346 on human basophils has recently been described during SARS-CoV2 infections<sup>38</sup> although it is not  
347 directly induced by the virus<sup>39</sup>. Interestingly, basopenia occurs in acute SARS-CoV2 infection  
348 suggesting putative recruitment of basophils to SLO<sup>40</sup>. This hypothesis is further supported by  
349 basophil overexpression of CXCR4 and CD62L in the SARS-CoV-2 infection setting, similar to what we  
350 described in SLE patients<sup>10,11,40,41</sup>. Normalization of both blood basophil numbers and activation  
351 markers is associated with the humoral response and recovery of COVID-19 patients<sup>40,42</sup>. This may  
352 indicate a role for PD-L1-overexpressing basophils in TFH cell induction to promote antiviral humoral  
353 response. EF responses occurring in lupus-prone mice and during some infections can quickly  
354 involute if new plasmablasts are not generated<sup>25</sup>. Thus, controlling basophil function or localization in  
355 SLO during viral infections may represent interesting therapeutic strategies to promote or sustain the  
356 antiviral humoral response.

357 Unexpectedly, when injected with pristane, mice with IL-4-deficient basophils still showed some  
358 plasmablast accumulation in SLO and C3 kidney deposits despite the absence of TFH cell  
359 accumulation, anti-RNP IgG induction, and IgG kidney deposits. Unlike pristane-injected basophil-  
360 deficient mice or mice with PD-L1-deficient basophils, *Mcpt8<sup>CT/+</sup>Il4<sup>fl/fl</sup>* mice developed high titers of  
361 anti-RNP IgM. This indicates that basophils express factors other than IL-4 in SLO during lupus-like  
362 disease responsible for their PD-L1-dependent action on B cell maturation into plasmablast in the  
363 absence of TFH cell pathogenic accumulation. However, it strongly suggests as well that basophil-  
364 derived IL-4 is mandatory for autoantibody class switch towards IgG in the lupus-like context. Further  
365 characterization of this B cell–basophil relationship in SLO in the SLE context will be required to  
366 identify basophil-derived factors that contribute to TFH-independent plasmablast proliferation.

367 Our study establishes a direct link between basophils and TFH cells in the SLE context that promotes  
368 autoreactive IgG production and lupus nephritis pathogenesis. Altering the basophil/TFH cell axis in  
369 the SLE context may represent a promising innovative intervention strategy in SLE.

474 **differentiation**

475 (a-k) Purified wild-type naïve CD4<sup>+</sup> T cells were cultured in plates coated with anti-CD3 and anti-CD28  
476 antibodies for three days without (–, grey filled bars) or with purified basophils from the following  
477 mice: *Mcpt8*<sup>CT/+</sup> (WT) (blue filled bars), *Mcpt8*<sup>CT/+</sup> *Il4*<sup>fl/fl</sup> (*Il4*<sup>fl/fl</sup>, IL-4-deficient basophils) (red filled bars),  
478 *Mcpt8*<sup>CT/+</sup> *Il6*<sup>fl/fl</sup> (*Il6*<sup>fl/fl</sup>, IL-6-deficient basophils) (orange filled bars), or *Mcpt8*<sup>CT/+</sup> *Pdl1*<sup>fl/fl</sup> (*Pdl1*<sup>fl/fl</sup>, PD-L1-  
479 deficient basophils) (green filled bars). (a) Proportions (%) of TFH among CD4<sup>+</sup> T cells after three days  
480 of culture as described in **methods**. (b-e) Proportions (%) of IL-21- (b), IL-6- (c), IL-4- (d), and IL-13- (e)  
481 producing cells among TFH cells non-restimulated and incubated with brefeldin A for the last 4 hours  
482 of the culture. (f) Representative histograms of PD-L1 expression on purified spleen basophils, from  
483 mice with the indicated genotype, co-cultured for three days without (dotted lines) or with activated  
484 naïve CD4 T cells (solid lines) (as described above). (g) PD-L1 expression levels on basophils, from  
485 mice as described above, cultured without (–, light colors) or with (+, dark colors) purified wild-type  
486 CD3/CD23-activated naïve CD4<sup>+</sup> T cells for three days. (h) Representative contour plots showing IL-6  
487 and IL-4 spontaneous production of basophils of the indicated genotype after three days of culture  
488 without (–) or with activated CD4<sup>+</sup> T cells and in the presence of brefeldin A for the last 4 hours of  
489 culture. (i,j,k) Proportions (%) of spontaneous IL-4- (i), IL-6- (j), and IL-13- (k) producing cells among  
490 basophils of the indicated genotypes cultured as described above. (a-k) Results for the same cells but  
491 re-stimulated with PMA and ionomycin are shown in **Fig. S4d-j**. (a-e, g, i-k) Results are from at least  
492 three independent experiments and presented as individual values in bars representing the mean ±  
493 s.e.m.. (a) Statistical analyses were done by a Kruskal-Wallis test followed by Dunn's multiple  
494 comparisons tests. (b-e, g, i-k) Statistical analyses were done by Mann-Whitney U test between the  
495 indicated groups. NS: not significant, p>0.05; \*: p<0.05; \*\*: p<0.01; \*\*\*: p<0.001; \*\*\*\*: p<0.0001.

496

541 **Figure 7: Human basophils drive TFH differentiation through IL-4, IL-6, and PD-L1 dependent**  
542 **mechanisms *ex vivo***

543 (a,b) Representative contour plots showing CD3/CD28-activated human CD4<sup>+</sup> T cells cultured for  
544 three days without (a) or with (b) purified human basophils at a 5:1 ratio (left panels) and the  
545 condition-induced TFH differentiation of the CD4<sup>+</sup> T cells (right panels). Basophils were defined as  
546 FcεRIα<sup>+</sup> CRTH2<sup>+</sup> CCR3<sup>+</sup> cells and TFH cells were defined as CD4<sup>+</sup> PD1<sup>+</sup> CXCR5<sup>+</sup> ICOS<sup>+</sup> cells. (c)

547 Proportions (%) of TFH among CD3/CD28-activated CD4<sup>+</sup> T cells after three days of culture without  
548 (0:1) or with the indicated ratio of purified human basophils. **(d)** Proportions (%) of TFH cells among  
549 CD3/CD28-activated CD4<sup>+</sup> T cells after three days of culture without (CD4<sup>+</sup> T cells alone) or with  
550 purified human basophils at a ratio of 1:5 in the absence (–) (blue filled bars) or presence of  
551 antibodies blocking IL-4 (αIL-4) (red filled bars), IL-6 (αIL-6) (orange filled bars) or PD-1 (αPD-1) (green  
552 filled bars) or the corresponding isotype controls (Iso) (blue filled bars). **(e)** Representative contour  
553 plots showing subsets of TFH cells as defined in the upper left panel based on CCR6 and CXCR3  
554 expressions on cells as in **(a)**. **(f)** Proportions (%) of TFH2 cells among TFH cells after culture as  
555 described in **(d)**. TFH2 cells were defined as CD4<sup>+</sup> PD1<sup>+</sup> CXCR5<sup>+</sup> ICOS<sup>+</sup> CCR6<sup>–</sup> CXCR3<sup>–</sup> cells. **(c,d)** Data  
556 are presented as individual values in bars representing the mean values ± s.e.m. **(c)** One  
557 representative experiment with cells from 4 different donors is shown. **(d,f)** Results are from three  
558 independent experiments. **(c,d,f)** Statistical analyses were done by one-way ANOVA test followed by  
559 Tukey's multiple comparisons tests between the indicated groups. NS: not significant, p>0.05; \*\*:  
560 p<0.01; \*\*\*: p<0.001; \*\*\*\*: p<0.0001.

561

562

## 563 MATERIAL AND METHODS

### 564 Patients

565 Blood samples were collected from adult patients enrolled in a prospective long-term study of  
566 systemic lupus erythematosus (SLE) and chronic renal diseases. All SLE patients fulfilled the American  
567 College of Rheumatology (ACR) classification criteria for SLE. SLE and healthy control (CT) donor  
568 characteristics are shown in **Table S1**. SELENA-SLEDAI (Safety of Estrogens in Lupus Erythematosus  
569 National Assessment - SLE Disease Activity Index) scores were assessed to evaluate patients' lupus  
570 activity who were classified as inactive (0-1), mild (2-4), and active (> 4). The study was approved by  
571 the Comité Régional de Protection des Personnes (CRPP, Paris, France) under the reference ID-RCB  
572 2014-A00809-38. SLE samples were obtained from in- and outpatients and clinical data were  
573 harvested after approval by the Commission Nationale de l'Informatique et des Libertés (CNIL). All  
574 samples were collected in heparinized tubes (BD vacutainer) and processed within 4 hours. Written  
575 informed consent was obtained from all individuals.

### 576 Mice

577 *Mcpt8<sup>DTR</sup>*<sup>43</sup>, *Lyn<sup>-/-</sup> Mcpt8<sup>DTR</sup>*<sup>11,44</sup>, *Il4<sup>fl/fl</sup>*<sup>22</sup>, *Il6<sup>fl/fl</sup>*<sup>23</sup>, and *Pdl1<sup>fl/fl</sup>*<sup>24</sup> mice were on a pure C57BL/6J  
578 background and bred in our animal facilities. Rosa26-loxP-Stop-loxP-DTA C57BL/6J (*R26<sup>DTA/DTA</sup>* or *R26<sup>DTA/+</sup>*)  
579 mice<sup>45</sup> were purchased from The Jackson Laboratory through Charles River Laboratories. CT-M8  
580 (*Mcpt8<sup>tm1.1(cre)lcs</sup>* or *Mcpt8<sup>CT/CT</sup>* or *Mcpt8<sup>CT/+</sup>*) mice were recently described<sup>12</sup>. The mice crossed in our  
581 animal facilities (*Mcpt8<sup>CT/+</sup>*, *Mcpt8<sup>CT/+</sup> Il4<sup>fl/fl</sup>*, *Mcpt8<sup>CT/+</sup> Il6<sup>fl/fl</sup>*, *Mcpt8<sup>CT/+</sup> Pdl1<sup>fl/fl</sup>* and *Mcpt8<sup>CT/+</sup> R26<sup>DTA/+</sup>*)  
582 were on a C57BL6J/N mixed genetic background at the F2 generation. For lupus-like disease analysis  
583 of the *Lyn<sup>-/-</sup>* model, "aged" *Mcpt8<sup>DTR</sup>* and *Lyn<sup>-/-</sup> Mcpt8<sup>DTR</sup>* age-matched and sex-matched mice  
584 were analyzed between 30 and 45 weeks of age (50% males and 50 % females). Mice were  
585 maintained under specific pathogen-free conditions in our animal facilities. The study was conducted  
586 in accordance with the French and European guidelines and approved by the local ethics committee

587 comité d'éthique Paris Nord N°121 and the Ministère de l'enseignement supérieur, de la recherche  
588 et de l'innovation under the authorization number APAFIS#14115.

### 589 **Human samples handling**

590 Heparinized human blood samples were centrifuged at 600 g for 5 minutes and 2 mL of plasma were  
591 collected and stored at -80°C for later analysis. Red blood cells (RBC) were lysed in RBC lysing buffer  
592 (150 mM NH<sub>4</sub>Cl, 12 mM NaHCO<sub>3</sub>, 1 mM EDTA, pH 7.4) in a ratio of 5mL of blood for 20mL of ACK  
593 lysing buffer. After 5 min of incubation at room temperature (rt), 25mL of PBS were added and cells  
594 were centrifuged at 600 g for 5 min, and the supernatant was discarded. This procedure was  
595 repeated 3 times. Leukocytes were then resuspended in fluorescence-activated cell sorting (FACS)  
596 buffer (PBS 1% BSA, 0.01% NaN<sub>3</sub>, 1mM EDTA) and prepared for flow cytometry (see below).  
597 Leukocyte count and viability (>95%) were assessed by trypan-blue staining on a Malassez  
598 hemacytometer.

### 599 **Pristane-induced lupus-like mouse model**

600 Pristane-induced lupus-like disease was initiated by injecting 500 µL of 2,6,10,14-  
601 tetramethylpentadecane or Pristane (Sigma) into the peritoneal cavity of 7-10 weeks-old female  
602 mice. For control individuals, genotype- and age-matched female mice were injected with 500 µL of  
603 phosphate buffer saline pH 7.4 (PBS) (Gibco). Mice were attributed to PBS- or pristane-injected  
604 groups randomly and maintained in the same cage for the whole procedure. Pristane- and PBS-  
605 injected mice were analyzed 8 weeks after injection.

### 606 **DT-mediated basophil depletion in lupus-like context**

607 For diphtheria toxin (DT)-mediated basophil depletion, *Mcpt8<sup>DTR</sup>*, and *Lyn<sup>-/-</sup> Mcpt8<sup>DTR</sup>* mice were  
608 injected intraperitoneally with 100 µL of PBS containing (or not) 1 µg of DT (Sigma) 10, 9, 6, 2 and 1  
609 day before the sacrifice.

### 610 **Mouse OVA immunization experiments**

611 10 to 15 weeks old C57/BL6J *Mcpt8<sup>DTR</sup>* sex-matched mice were immunized by intraperitoneal  
612 injection of 200  $\mu$ L of a 50/50 emulsion of Alum (ThermoFisher Scientific) with 100  $\mu$ g of ovalbumin  
613 (OVA, Sigma-Aldrich) diluted in PBS or with PBS alone for control mice. A similar injection was  
614 performed on day 7 and the mice were sacrificed on day 14. For DT-mediated basophil depletion, 1  
615  $\mu$ g of DT (or PBS as a control) was injected intraperitoneally on day 12 and day 13.

#### 616 **Mouse samples processing**

617 Mice were euthanized in a controlled CO<sub>2</sub> chamber (TEM Segal) and blood sampling was performed  
618 through cardiac puncture with a heparin-coated syringe with a 25G needle. Blood was centrifuged at  
619 300 g for 15 min and plasma was harvested and kept at -80°C for later analysis. RBC were lysed in  
620 5mL of RBC lysing buffer for 5 min at rt and washed with 10mL of PBS. This procedure was repeated 3  
621 times and cells were resuspended in PBS. The left kidney was harvested and embedded in OCT  
622 embedding matrix (Cellpath) and snap-frozen in liquid nitrogen and kept at -80°C for later analysis.  
623 Spleen and lymph nodes (cervical, brachial and inguinal) were harvested in PBS and dissociated by  
624 mechanical disruption on a 40  $\mu$ m cell strainer (Falcon, Corning). For splenocytes, RBC were lysed  
625 once in 5mL RBC lysing buffer 5 min at rt and washed with 10mL of PBS. Cell counts were assessed by  
626 trypan-blue staining on a Malassez hemacytometer and 1 to 5 million cells were used per FACS  
627 staining condition.

#### 628 ***Ex vivo* stimulation of splenocytes.**

629 Mouse splenocytes were harvested as described above and resuspended at 5 million cells/mL in  
630 culture medium (RPMI 1640 with Glutamax and 20mM HEPES, 1mM Na-pyruvate, non-essential  
631 amino acids 1X (all from Life Technologies), 100  $\mu$ g/mL streptomycin and 100 U/mL penicillin (GE  
632 Healthcare) and 37.5  $\mu$ M  $\beta$ -mercaptoethanol (Sigma-Aldrich) supplemented with 20% heat-  
633 inactivated fetal calf serum (FCS) (Life Technologies)). For phorbol-myristate-acetate (PMA) and  
634 ionomycin stimulation experiments, whole splenocytes were stimulated or not with 40 nM of PMA  
635 and 800 nM ionomycin for 4 hours in the presence of 2  $\mu$ g/mL of brefeldin A (all from Sigma Aldrich,

636 Merck) and cultured at 37°C and 5% CO<sub>2</sub>. Then, cells were harvested by repeated flushing, and wells  
637 were washed with 1mL of PBS. Samples were then prepared for flow cytometry analysis.

### 638 **Flow cytometry staining**

639 For human leukocytes, non-specific antibody binding sites were saturated with 20 µL of a solution  
640 containing 100 µg/mL of human, mouse, rat, and goat IgG (Jackson ImmunoResearch Europe and  
641 Innovative Research Inc.) in FACS buffer. 200 µL of staining solution containing the panel of  
642 fluorophore-conjugated specific antibodies or their fluorophore-conjugated isotypes (described in  
643 the **antibodies and reagents table**) were added to the cells for 30 min at 4°C protected from light.  
644 After a wash in PBS, cells were fixed in fixation buffer (Biolegend) for 20 minutes at 4°C and then  
645 washed in FACS buffer before data acquisition. For mouse samples, cells washed in PBS were stained  
646 with GHOST 510 viability dye (TONBO) following the manufacturer's instructions. Non-specific  
647 antibody binding sites were saturated with 10 µg/mL of anti-CD16/CD32 antibody clone 2.4G2  
648 (BioXCell), and 100 µg/mL of polyclonal rat, mouse, and Armenian Hamster IgG (Innovative Research  
649 Inc.) in FACS buffer and stained with the antibodies described in the **antibodies and reagents table**  
650 for 30 min in the dark at 4°C. Cells were then washed in FACS Buffer before data acquisition. For  
651 intracellular staining, cells were first stained extracellularly as described above. Cells were washed in  
652 PBS and fixed with fixation buffer for 20 min at 4°C. Cell permeabilization and intracellular staining  
653 were realized with permeabilization/wash buffer (Biolegend) following the manufacturer's  
654 instructions. Cells were then resuspended in FACS buffer before acquisition All flow cytometry  
655 acquisitions were realized using a Becton Dickinson 5 lasers LSR Fortessa X-20 and data analysis using  
656 Flowjo vX (Treestar, BD Biosciences). For assessment of surface marker expression levels, ratios of  
657 the geometric mean fluorescence intensity (gMFI) of the markers to the gMFI of the corresponding  
658 isotype control were calculated and expressed in arbitrary units (A.U.).

### 659 **Kidney Immunofluorescence assays**

660 4  $\mu\text{m}$  thick cryosections of OCT-embedded kidneys were fixed 20 min in ice-cold acetone and kept a -  
661 80°C until immunofluorescence staining. Slides were thawed and fixed in 10% formalin (Sigma) for 20  
662 min at room temperature and blocked with PBS containing 1% BSA (Euromedex) and 5% goat serum  
663 (Sigma-Aldrich). Slices were stained for 2 hours at room temperature in the dark in a humid chamber  
664 with FITC-conjugated anti-mouse C3 (Cedarlane), Alexa Fluor® 488-conjugated anti-mouse C3 (Santa  
665 Cruz Biotech), Alexa Fluor® 488-conjugated goat anti-mouse IgG Fc $\gamma$ -specific (Jackson  
666 Immunoresearch), FITC-conjugated goat anti-mouse IgM (BioRad (AbD Serotec)) or corresponding  
667 isotype controls. Slides were mounted in Immunomount (Thermofischer Scientifics) and analyzed by  
668 fluorescent microscopy (Leica DMR, Leica microsystems). The ratio of specific glomerular  
669 fluorescence over tubulointerstitial background was then measured using ImageJ software v. 1.43u  
670 (NIH), averaging at least 30 glomeruli per mouse for each sample.

#### 671 **Anti-RNP IgG and IgM autoantibody detection**

672 Maxisorp 96 well plates (Thermo Scientific) were coated overnight at 4°C with 10  $\mu\text{g}/\text{mL}$  of purified  
673 RNP complexes (Immunovision) diluted in carbonate buffer (100 mM  $\text{NaHCO}_3$  and 30 mM  $\text{Na}_2\text{CO}_3$  pH  
674 9.6). Plates were washed 3 times in PBS containing 0.1% of Tween-20 (Bio-Rad laboratories) (PBS-T)  
675 and saturated for 1 hour with PBS containing 5% of FCS. For anti-RNP IgG quantification, plasma  
676 samples were diluted 1:25 in PBS-T containing 5% of goat serum and 100  $\mu\text{L}$  added to the wells.  
677 Samples, positive and negative controls were incubated for 2 hours at rt. Plates were washed 5 times  
678 with PBS-T. 100  $\mu\text{L}$  of either 500 ng/mL goat anti-mouse IgG (Invitrogen) or 10 ng/mL goat anti-  
679 mouse IgM (Bethyl laboratories) conjugated to horseradish peroxidase (HRP) diluted in PBS-T  
680 containing 5% goat serum were added and incubated 1h at room temperature. After 5 washes in  
681 PBS-T, 100  $\mu\text{L}$  of tetramethylbenzidine (TMB) substrate (ThermoFisher) were added to the wells and  
682 incubated at least 20 min at rt and the reaction was stopped with 0.2N sulfuric acid solution. Optical  
683 density at 450 nm was measured by spectrophotometry (Infinite 200 Pro plate reader, TECAN). On  
684 each plate, similar negative and positive controls were run. Optical density (OD) values were first

685 normalized to the negative controls and then, the presented results were normalized to the mean of  
686 the control mice values and expressed in arbitrary units (A.U.).

### 687 **Anti-dsDNA IgG detection**

688 Maxisorp 96 well plates (Thermo Scientific) were coated overnight at 4°C with calf thymus dsDNA  
689 (Sigma-Aldrich) diluted in TE buffer (Tris-HCl 10 mM, EDTA 1 mM pH 9) at a concentration of 2 µg/mL  
690 and diluted in the same volume of Pierce DNA coating solution (Thermo Scientific) to obtain a final  
691 concentration of 1µg/mL of dsDNA. The same protocol as for anti-RNP IgG was then followed but the  
692 PBS-T contained 0.05% of Tween-20.

### 693 **Cell sorting and co-culture**

694 For mouse co-culture experiments, F(ab')<sub>2</sub> anti-CD3 (clone145-2C11 at 0,5 µg/mL) and anti-CD28  
695 (clone PV-1 at 0,5 µg/mL) antibodies (BioXcell) were coated overnight at 4°C in culture 96 well plates  
696 (Costar) in sterile-filtered coating buffer (20 mM carbonate buffer (pH 9.6) containing 2 mM MgCl<sub>2</sub>  
697 and 0.01% NaN<sub>3</sub>). Wells were washed in PBS before plating the cells. Spleens were harvested and  
698 handled as described above and resuspended at 10<sup>8</sup> cells/mL in PBS containing 2% FCS and 2mM  
699 EDTA. Naïve CD4<sup>+</sup> T cells were sorted by magnetic negative selection following manufacturer  
700 protocol (Stemcell Technologies) and resuspended in culture medium at 0.5 million cells/mL. 100 µL  
701 of naïve CD4<sup>+</sup> T cell suspension were then added to wells of interest. Basophils from CTM8 mice were  
702 purified over 98% by electronic sorting using the BD FACSMelody Cell Sorter (BD Biosciences) using  
703 the tandem tomato fluorescent protein as a specific marker<sup>12</sup>. Basophils were re-suspended in  
704 culture medium at 0.1 million cells/mL and 100µL were added to wells of interest. All wells were  
705 supplemented with 10 pg/mL of recombinant mouse IL-3 (Peprotech). After 3 days of culture at 37°C  
706 5% CO<sub>2</sub>, cells were harvested and prepared for flow cytometry as described above. For cytokine  
707 production detection, cells were stimulated or not for the last 4 hours with 40 nM PMA and 800 nM  
708 ionomycin in the presence of 2 µg/mL brefeldin A (Sigma-Aldrich, Merck) and prepared for flow  
709 cytometry as described above.

710 For human co-culture experiments, 96 well plates (Costar) were coated overnight at 4°C in coating  
711 buffer containing 5 µg/mL of mouse anti-human CD3 (clone OKT3) (Thermo Fischer Scientific). Blood  
712 from healthy volunteers was handled and lysed as described above in sterile conditions and re-  
713 suspended at  $5 \times 10^7$  cells/mL in PBS 2% FCS (Gibco) 2mM EDTA. Naïve CD4<sup>+</sup> T cells and basophils  
714 were sorted by magnetic negative selection following manufacturer instructions (Stemcell  
715 Technologies). Naïve CD4<sup>+</sup> T cells were re-suspended in culture medium at 0.5 million cells/mL. and  
716 100 µL of cell suspension were then added to each well. Basophils were resuspended in culture  
717 medium at 0.1 million cells/mL and 100µL were added to each well unless otherwise specified. All  
718 wells were supplemented with 10 pg/ml of recombinant human IL-3 (Biolegend) and 2 µg/mL of  
719 mouse anti-human CD28 antibody (Clone CD28.2 at (BioXcell)). When indicated, some wells were  
720 supplemented with mouse anti-human blocking antibodies targeting IL4 (Clone MP4-25D2), IL-6  
721 (Clone MQ2-13A5), both at 5 µg/mL or PD-1 (Clone EH12.2H7 at 10µg/mL) or with the corresponding  
722 isotypes at the same concentrations. Cells were harvested after 3 days of culture at 37°C 5% CO<sub>2</sub> and  
723 prepared for flow cytometry as described above.

#### 724 **Statistical analysis**

725 Two-tailed Student's unpaired t-tests were used to compare the differences of one variable between  
726 two groups when distributions were Gaussian and Mann-Whitney U tests for non-parametric  
727 distributions. When more than two groups were compared, one-way ANOVA coupled with *ad hoc*  
728 multiple comparisons post-tests, as indicated in the figure legends depending on the distribution of  
729 the values in each group, were used. Statistical analyses were realized using Prism v9.4 software  
730 (Graphpad).

#### 731 **Antibodies, reagents, software and equipments**

732 See Supplementary Table S3.

863

864 **GRAPHICAL ABSTRACT**

865  
866 Pathogenic accumulation of T follicular helper cells in lupus disease depends on PD-L1 and IL-4  
867 expressing basophils.
