

## 15 **Abstract**

16 **Background:** Amid persistent disparities in Covid-19 vaccination, we conducted a scoping  
17 review to identify multilevel determinants of Covid-19 vaccine hesitancy (VH) and  
18 undervaccination among marginalized populations in the U.S.

19 **Methods:** We utilized the scoping review methodology developed by the Joanna Briggs Institute  
20 and report all findings according to PRISMA-ScR guidelines. We developed a search string and  
21 explored 7 databases to identify peer-reviewed articles published from January 1, 2020–October  
22 31, 2021, the initial period of U.S. Covid-19 vaccine availability. We combine frequency  
23 analysis and narrative synthesis to describe factors influencing Covid-19 vaccination among  
24 marginalized populations.

25 **Results:** The search captured 2,496 non-duplicated records, which were scoped to 50 peer-  
26 reviewed articles: 11 (22%) focused on African American/Black people, 9 (18%) people with  
27 disabilities, 4 (8%) justice-involved people, and 2 (4%) each on Latinx, people living with  
28 HIV/AIDS, people who use drugs, and LGBTQ+ people. Forty-four articles identified structural  
29 factors, 36 social/community, 27 individual, and 40 vaccine-specific factors. Structural factors  
30 comprised medical mistrust (of healthcare systems, government public health) and access  
31 barriers due to unemployment, unstable housing, lack of transportation, no/low paid sick days,  
32 low internet/digital technology access, and lack of culturally and linguistically appropriate  
33 information. Social/community factors including trust in a personal healthcare provider (HCP),  
34 altruism, family influence, and social proofing mitigated VH. At the individual level, low  
35 perceived Covid-19 threat and negative vaccine attitudes were associated with VH.

36 **Discussion:** This review indicates the importance of identifying and disaggregating structural  
37 factors underlying Covid-19 undervaccination among marginalized populations, both cross-

38 cutting and population-specific—including multiple logistical and economic barriers in access,  
39 and systemic mistrust of healthcare systems and government public health—from individual and  
40 social/community factors, including trust in personal HCPs/clinics as reliable sources of vaccine  
41 information, altruistic motivations, and family influence, to effectively address individual  
42 decisional conflict underlying VH as well as broader determinants of undervaccination.

43

44 **Keywords**

45 Vaccination hesitancy, Covid-19 vaccines, medical mistrust, social determinants of health,  
46 access to care, ethnic and racial minorities

## 47 **Introduction**

48           Vaccination remains an essential component of public health strategies to control the  
49 Covid-19 pandemic. Vaccination has reduced Covid-19-related morbidity and mortality in the  
50 United States (U.S.) [1], and globally—with an estimated 63% (14.4–19.8 million) reduction in  
51 deaths in the first year of Covid-19 vaccination alone [2]. Vaccine booster doses [3], and bivalent  
52 vaccine boosters compared with past monovalent vaccination [4], have further reduced Covid-  
53 19-associated hospitalization and death. Yet, despite the tremendous successes of Covid-19  
54 vaccination, pervasive challenges ascribed to vaccine hesitancy (VH), and broader Covid-19  
55 undervaccination, threaten the effectiveness of vaccines in controlling Covid-19 and other  
56 vaccine-preventable diseases.

57           The World Health Organization (WHO) Strategic Advisory Group of Experts (SAGE) on  
58 Immunization defines vaccine hesitancy (VH) as “delay in acceptance or refusal of vaccination  
59 despite availability of vaccination services” [5,p.4161]. In addition to individual-level correlates  
60 of VH, SAGE [6] along with other research initiatives [7,8] have drawn attention to the critical  
61 importance of vaccine availability and access—amid systematic variations in vaccine coverage  
62 across countries and subpopulations—and issues that may pertain to specific vaccines.  
63 Collectively, these challenges support the need to identify and examine multilevel factors that  
64 contribute to Covid-19 VH and broader Covid-19 undervaccination (e.g., due to inaccessibility,  
65 unavailability) [9].

66           Disparities in Covid-19 morbidity and mortality, as well as lower rates of Covid-19  
67 vaccination, are well documented among marginalized populations in the U.S. [10-13].  
68 Marginalization is defined by systemic processes driven by ideologies such as racism, sexism,  
69 heterosexism, cissexism, ableism, and xenophobia, that exclude certain populations or relegate

70 them to the periphery of political and socioeconomic resources [14,15]. The structural and social  
71 inequities produced by marginalization create adverse social determinants of health (SDOH)—  
72 such as residential segregation and housing insecurity, employment precarity, income insecurity,  
73 lack of access to affordable healthcare, barriers to physical mobility, and stigmatization—all of  
74 which increase vulnerability to poor health outcomes [14]. Adverse SDOH exacerbate  
75 vulnerability to Covid-19 through the disproportionate prevalence of underlying conditions  
76 associated with worse Covid-19 outcomes, lower levels of health insurance and healthcare  
77 access, and by impeding the ability to practice public health measures to reduce viral  
78 transmission [16-19]. Although heightened vulnerability indicates an increased need for  
79 vaccination, these same SDOH may contribute to *lower* levels of Covid-19 vaccination [20,21].  
80 In fact, across 45 U.S. states, 0.1%–24.9% lower vaccination was documented among Blacks vs.  
81 Whites, 0.0%–37.6% lower among Hispanics vs. Whites, as of May 2021—with state-level rate  
82 differences significantly associated with a metric of structural racism [21]. In a national study,  
83 eligible healthcare facilities and community pharmacies in counties with higher Black  
84 composition were significantly less likely to provide Covid-19 vaccination [20].

85         Although some of the racial/ethnic disparities in Covid-19 vaccination documented  
86 earlier in the pandemic have reportedly narrowed over time, attributed in part to the success of  
87 targeted interventions [11], disparities persist in lower administration of booster doses among  
88 Black, Hispanic/Latinx, and American Indian populations versus Whites [22]. Consistent with  
89 the “inverse equity hypothesis,” with each innovation in Covid-19 vaccines, uptake is predicted  
90 to be greater among wealthier and more socially connected segments of the population, thereby  
91 increasing rather than reducing inequity [23,24]. Nevertheless, population-level disparities in  
92 Covid-19 vaccination are often conceptualized as contingent on individual-level factors (e.g.,

93 low perceived threat, vaccine attitudes) to the relative underemphasis of structural and systemic  
94 factors [20,21,25,26]. Moreover, trust/mistrust in a personal HCP as a source of reliable  
95 information [27] is often conflated with systemic medical mistrust: distrust of healthcare  
96 systems, government public health, medical treatments, and/or the pharmaceutical industry  
97 arising from present-day experiences of discrimination and/or historical experiences of  
98 discrimination and injustice in the healthcare system [28-30].

99 Building on the SAGE “Vaccine Hesitancy Determinants Matrix” and recommendations  
100 to approach VH as a population- and context-specific phenomenon [6,31], along with critiques of  
101 the lack of clarity in the definition and application of VH [32-34], we conducted a scoping  
102 review to examine multilevel factors associated with Covid-19 VH and broader Covid-19  
103 undervaccination among marginalized populations in the U.S.

104

## 105 **Methods**

106 A scoping review was conducted given our aim of mapping the evidence landscape [35]  
107 on factors associated with Covid-19 VH and undervaccination among marginalized populations.

108 A scoping review protocol, including our search strategy and review process, has been  
109 previously published [36]. We utilized the scoping review methodology described by Arksey and  
110 O’Malley [37], further developed by the Joanna Briggs Institute [38], with all results reported in  
111 accordance with PRISMA Extension for Scoping Reviews (PRISMA-ScR) guidelines [39].

112

## 113 **Research question**

114 This scoping review was guided by the question, “What are the determinants of Covid-19  
115 ‘vaccine hesitancy’ reported among marginalized populations in the U.S. and Canada?”, with

116 sub-questions, “what are the focal populations in studies of Covid-19 VH and undervaccination  
117 among marginalized populations?” and “what are the contexts and determinants of Covid-19 VH  
118 and undervaccination by structural, social and community, individual, and vaccine-specific  
119 factors?” [36].

120

## 121 **Information sources and search strategy**

122 We identified the following list of databases to search in consultation with a specialist  
123 research librarian: Medline, Embase, Cochrane CENTRAL, Cochrane Covid-19 Study Register,  
124 PsychINFO, Sociological Abstracts, and the International Bibliography of the Social Sciences  
125 (IBSS). We then developed a search string with keywords and synonyms related to vaccine  
126 hesitancy (i.e., “vaccine hesitancy”, “vaccine refusal”, “vaccine confidence”, “vaccine distrust”,  
127 “vaccine mistrust”, “vaccine barriers”) and Covid-19 (i.e., “corona virus” or “coronavirus” or  
128 “COVID” or “nCoV” along with adjacent terms “19” or “2019, or “SARS-CoV-2” or “SARS  
129 Coronavirus 2”, etc.). S1 Table shows an example search string for Medline and Embase. We  
130 adapted the search string to accommodate differences in syntax and parameters among the  
131 selected databases.

132

## 133 **Study selection criteria**

134 We developed inclusion and exclusion criteria prior to conducting the search for peer-  
135 reviewed articles published between January 1, 2020 and October 31, 2021: 1) populations in the  
136 U.S. or Canada; 2) adults  $\geq 18$  years; 3) focused on (>50%) marginalized populations, 4) focused  
137 on Covid-19 vaccine hesitancy, refusal, confidence, mistrust, or barriers. Articles were excluded  
138 if they were 1) published prior to 2020; 2) not written in English; 3) focused on healthcare

139 workers, staff, or students/interns; or 4) focused on children (<18 years) or parents' vaccination  
140 of children. We selected search dates corresponding to the declaration of Covid-19 as a public  
141 health emergency through the initial authorization of Covid-19 vaccines for the adult population  
142 in the U.S. and Canada in December 2020, until U.S. FDA and Health Canada recommendations  
143 for the first booster vaccines, beginning in late September 2021 to early November 2021 [40,41].

144 We identified marginalized populations informed by a review of populations particularly  
145 vulnerable to discrimination and exclusion in healthcare [42] or due to broader adverse SDOH  
146 [14]. The populations include those marginalized in relation to their race or ethnicity, sexual  
147 orientation or gender identity, physical or mental disability, persons living with HIV,  
148 immigrants/refugees, persons who experience homelessness, justice-involved people, and people  
149 who use drugs, along with their intersections (e.g., Latinx immigrants).

150

## 151 **Study selection process**

152 Search results of peer-reviewed articles were uploaded into Covidence software. Multiple  
153 research team discussions ensured consistent application of inclusion/exclusion criteria. Initially  
154 groups of two reviewers (among LR, TN, DD, KA, SF or ST) independently screened abstracts  
155 and titles until we attained inter-rater reliability of 90% [43]; this was achieved after two rounds  
156 of abstract review and team discussions to achieve consensus. Subsequently, in accordance with  
157 rapid review methods, one reviewer screened each abstract/title to determine inclusion or  
158 exclusion [44]. One reviewer (TN, DD, KA, SF or ST) then screened each full-text for inclusion.  
159 Full-text articles designated for exclusion were then reviewed by a single arbitrator (PN), with  
160 discrepancies resolved by consensus among the research team [44,45].

161

## 162 **Data extraction and synthesis**

163 We abstracted data on publication characteristics (i.e., author(s), study sites, sample size,  
164 populations, methods, and domains of VH factors identified (see Table 1). We then reviewed the  
165 abstracted data using quantitative (i.e., frequency) analysis to describe study locales, sample  
166 sizes, focal populations, methods, and VH factor domains, and qualitative (i.e., narrative)  
167 analysis to synthesize the evidence on VH and undervaccination among each subpopulation.

168 All authors categorized publications by domains of factors identified, using a four-  
169 component framework informed by the “Vaccine Hesitancy Determinants Matrix” [6,31] and  
170 recommendations to disaggregate multilevel phenomena [8,33,34]. Domains comprised  
171 structural (e.g., access to vaccination site, medical mistrust); social/community (e.g., family  
172 support, trust in personal HCP or clinic, social proofing [i.e., based on actions of others in one’s  
173 community], community benefits); individual (e.g., perceived Covid-19 threat, perceived  
174 transmission risk, general vaccine beliefs); and Covid-19 vaccine-specific factors (e.g., vaccine  
175 safety, side effects, efficacy). One change to data extraction (but not inclusion) was made from  
176 the initial protocol in that we differentiated between medical mistrust at the “system-level” and  
177 trust in a personal HCP/clinic.

178

## 179 **Results**

180 The search captured 4,399 peer-reviewed articles in total, with 2,496 abstracts screened  
181 after removal of duplicates. We identified 363 full-text articles to be screened for eligibility, with  
182 a total of 50 peer-reviewed articles included [12,26,46-93]. The PRISMA flow diagram shows  
183 the process of identifying relevant peer-reviewed journal articles (see Fig 1).

184

185 **Figure 1. PRISMA flow diagram for scoping review of COVID-19 vaccine hesitancy and**  
186 **undervaccination among marginalized populations**

187

## 188 **Description of studies**

189 Among the 50 articles included, 86% were quantitative studies, 10% qualitative, and 4% mixed  
190 methods (see Table 1). Sample sizes ranged from n=24 to n=164,283 (N=499,237; median=437).

191 All studies were conducted in the U.S., including 24 (48%) national studies, 8 (16%) in the West,  
192 7 (14%) Northeast, 5 (10%) Midwest, 5 (10%) Southeast, and 1 (2%) in the Southwest region.

193 No studies were identified from Canada that met inclusion criteria within the timeframe of the  
194 review.

198 AA, African Americans; IMM, immigrants and refugees; Jl, justice-involved people; Latinx, Latinx/Hispanic people; LGBTQ+,  
199 Lesbian, gay, bisexual, transgender, queer and other sexual/gender minority people; PEH, people experiencing homelessness; PWD,  
200 people with disabilities; PLHA, people living with HIV/AIDS; PWUD, people who use drugs; Racial/Ethnic min., racial/ethnic  
201 minority.

202 Table 2 shows the number of focal articles by subpopulation, with 11 (22%) focused on  
203 African American/Black people, 9 (18%) on people with disabilities, 4 (8%) on justice-involved  
204 people, and 2 (4%) each on Latinx, people living with HIV/AIDS (PLHA), people who use drugs  
205 (PWUD), and lesbian, gay, bisexual, transgender, and queer (LGBTQ+) people. We allocated  
206 findings from articles broadly focused on racial/ethnic minorities to each of the subpopulations  
207 (i.e., African American/Black, Latinx, Asian, American Indian) for which disaggregated data  
208 were provided (i.e., one article could be a “source” for several populations). Four additional  
209 articles addressing VH pertaining to two subpopulations (e.g., African American/Black PLHA)  
210 were each allocated as two sources. Table 2 shows the total number of sources (n=73) addressing  
211 population-specific factors associated with VH across the 50 articles. Among these, 41.1% of  
212 sources (n=30) identified VH factors among African American/Black populations, 17.8% (n=13)  
213 Latinx populations, 12.3% (n=9) people with disabilities, and 5.5% (n=4) each Asian, justice-  
214 involved, and PLHA.

215 **Table 2. Focal articles and additional sources by subpopulation**

<b>Subpopulation</b>	<b>Focal articles on each sub-population</b>	<b>Additional sources addressing each subpopulation</b>	<b>Number (%) of total sources by sub-population (n=73)</b>
African American/Black	11	19	30 (41)
Latinx	2	11	13 (18)
People with disabilities	9	0	9 (12)
Justice involved	4	0	4 (5)
People living with HIV/AIDS	2	2	4 (5)
Asian people	0	4	4 (5)
People who use drugs	2	1	3 (4)
Immigrants/refugees	1	1	2 (3)
LGBTQ+ people	2	0	2 (3)
People experiencing homelessness	1	0	1 (1)
American Indians/Native	0	1	1 (1)
<b>Subtotal</b>	<b>34</b>	<b>39</b>	<b>73</b>

216 LGBTQ+, Lesbian, gay, bisexual, transgender, queer and other sexual/gender minority people

217

218 Fig 2 shows the number of articles addressing factors associated with VH in each of four  
 219 domains: structural, social/community, individual, and Covid-19-vaccine-specific. Table 3 shows  
 220 the domains of factors associated with VH in each subpopulation. Next, we describe findings  
 221 based on a narrative synthesis of factors associated with VH and undervaccination for each focal  
 222 population.

223  
 224 **Fig 2. Count of articles identifying factors in each of the four domains of Covid-19 vaccine**  
 225 **hesitancy and underutilization**

226  
 227 **Table 3. Population by domains of factors identified in Covid-19 vaccine hesitancy and**  
 228 **undervaccination**

People who use drugs	x		x	x

229 LGBTQ+, Lesbian, gay, bisexual, transgender, queer and other sexual/gender minority people

## 230 ***Black and African American people***

231           Eleven articles focused exclusively on Covid-19 vaccination among Black/African  
232 Americans [26,56,59,69,74,75,77,81,85,89,90], and 19 additional articles provided disaggregated  
233 data—a total of 30 sources [46-48,49,51-53,55,60,65-68,70,73,82,84,86,92]. At the structural  
234 level, 27 sources addressed the negative impacts of medical mistrust and distrust of government  
235 on Covid-19 vaccination among Black and African Americans [26,46-49,51-53,55,59,65-70,73-  
236 75,77,81,82,84-86,89,92]. Several studies described Covid-19 VH, such as due to fears of being  
237 experimented on with Covid-19 vaccines without consent, “based on...knowledge of historic  
238 mistreatment and unethical research practices that adversely impacted black patients and  
239 participants” [74, p.1786], including the legacy of the Tuskegee Study of untreated syphilis  
240 [53,67,68,77]. Eleven sources addressed barriers to present-day healthcare and Covid-19  
241 vaccines for Black/African Americans, including unemployment, housing insecurity, limited  
242 interactions with HCP, and difficulties travelling to vaccination sites [48,52,53,56,68-  
243 70,75,77,89,90].

244           At the social/community level, nine sources indicated the role of trust in HCPs in Covid-  
245 19 vaccination intentions [26,46,51,60,69,70,74,82,85]. Characteristic of many studies, "Blacks  
246 and Hispanics were more likely than Whites to state that it was ‘extremely’ important that a  
247 medical professional of their same race/ethnicity endorse the vaccine before they took it”  
248 [26,p.8]. Seven studies addressed the influence of families and communities on Covid-19  
249 vaccination [48,52,59,70,74,77,81], and further that “governmental agencies are less well-  
250 received as information sources compared to friends or family” [59, p.1103]. In one study,  
251 family influence promoted VH by casting doubt on public health information, rather than  
252 motivating vaccination [81].

253 At the individual level, four studies addressed negative impacts of religious beliefs,  
254 including preference for ‘natural’ medicines over vaccines, and general vaccine aversion on  
255 Covid-19 vaccination [67,74,77,81]. Covid-19 vaccine-specific concerns, identified in 14  
256 studies, included vaccine safety, adverse effects, and uncertain efficacy [26,51-53,59,67-  
257 70,73,74,77,81,90], and the importance of evidence of Covid-19 vaccine safety and efficacy  
258 specific to Black/African Americans: “any data that’s connected with some of the conditions that  
259 are prevalent in our community” [53, p.8].

260

### 261 *Latinx/Hispanic people*

262 Two studies focused on Covid-19 vaccination among Latinx/Hispanic people [50,61],  
263 with an additional 11 sources providing data specific to this population  
264 [26,46,48,49,53,60,67,68,70,73,82]. At the structural level, five studies identified negative  
265 impacts of medical mistrust [48,49,61,67,82], including fear of being used as “guinea pigs  
266 (conejillos de indias)” and of being sterilized [61]. Limited access to information in one’s  
267 preferred language, complicated online vaccination sign-up procedures, lack of insurance, and  
268 lack of transportation to vaccination sites posed barriers to Covid-19 vaccination  
269 [48,53,61,68,70]. Two studies underscored the importance of tailored vaccine education and  
270 accessible information [68]: “[a family member] doesn’t speak English...so, a lot of the  
271 information that he may have heard about the vaccine and Covid probably came off of Univision  
272 and Telemundo” [48, p.6].

273 At the social/community level, five studies described the important role of personal HCPs  
274 in Covid-19 vaccination among Latinx communities [26,46,60,70,82], including endorsement  
275 from an HCP of one’s own ethnicity [26]. Two studies addressed altruism and wanting to protect

276 one's community as a motivator of Covid-19 vaccination [53,61]. Families and close  
277 communities were described as playing an important role in Covid-19 vaccination knowledge  
278 and decision-making [48,61,70]: "79% of the youth had discussed health with their families for  
279 an average of 50 minutes [per week]" [61, p.753]. No individual-level factors were described,  
280 but Covid-19 vaccine-specific concerns arose around safety, adverse effects, and efficacy  
281 [26,61,67,68,70,73].

282

### 283 *Asian people*

284 No studies focused exclusively on Covid-19 vaccination among people of Asian descent  
285 in the U.S.; four sources provided disaggregated data on Asian people [46,53,64,67]. At the  
286 structural level, barriers included difficulties in accessing reliable translations and messengers of  
287 Covid-19 vaccine information [53]. Beyond linguistic translation, a Filipinx participant  
288 explained, "In terms of translators...maybe those who may not be of the same culture or the way  
289 that they're explaining the medical terminology may be intimidating" [53, p.6]. Medical mistrust  
290 was identified as negatively impacting vaccination intention [53,67], with trust in personal HCPs  
291 as sources of vaccine information positively associated with Covid-19 vaccination intention  
292 among Asian people [46]. Covid-19 vaccine-specific concerns arose around safety, adverse  
293 effects, and efficacy [53,64,67], including the need for population-specific evidence: "There has  
294 been a lot of concerns in my family on how the vaccine works for people with heart disease,  
295 which really affects...a lot of the Filipino community, and also those with respiratory diseases"  
296 [53, p.6].

297

298

299 ***American Indians***

300 No studies among those reviewed focused on Covid-19 vaccination among American  
301 Indians or Alaskan Natives; one source provided data on American Indians [53]. Structural  
302 factors arose regarding distrust of government, desire for autonomy (“to be respected”),  
303 challenges in access to digital technology and the internet, lack of quality translations and  
304 tailored information, lack of employment benefits, insurance, and transportation to get  
305 vaccinated [53]. In addition to distrust ascribed to the politicization of vaccination, a participant  
306 decried structural-level challenges for elders: “Some elders...they’re houseless...there’s no cell  
307 phone, they ride public transportation. How is it going to get distributed [to them]...the most  
308 vulnerable... it feels like our culture always gets the shitty end of the stick” [53, p.6]. Covid-19  
309 vaccine-specific concerns arose around side effects, efficacy, and multiple doses—associated  
310 with challenges for Native families due to the need for several trips to vaccination sites.  
311

312 ***LGBTQ+ people***

313 Two sources focused on Covid-19 vaccination among LGBTQ+ people [83,86]. At the  
314 structural level, medical mistrust based on historical discrimination against sexual and gender  
315 minorities was negatively associated with Covid-19 vaccination intentions [86]. Loss of  
316 employment and housing insecurity were described as factors that underscored the threat of the  
317 pandemic among LGBTQ+ people, thus motivating vaccination. At the social and community  
318 level, altruistic motivations were positively associated, while anticipated stigma was negatively  
319 associated with vaccination intentions [83,86]. Individual-level factors impacting vaccination  
320 were described in perceived threat of Covid-19: “negative experiences, along with the reported  
321 high levels of perception of the seriousness of Covid-19 infection, are likely driving the high

322 levels of willingness to be vaccinated” [83,p.9]. Covid-19 vaccine-specific concerns included  
323 adverse effects and safety [86].

324

### 325 *People with disabilities*

326 Nine articles focused on challenges in Covid-19 vaccination for people with disabilities  
327 (PWD) [12,57,58,64,67,72,76,88,91]. At the structural level, five studies addressed the impact of  
328 trust in government: three reported a positive association with Covid-19 vaccination [57,58,88],  
329 while two described governmental distrust contributing to VH [67,72]. Strict public health  
330 measures and widespread reliance on digital technology during the pandemic posed structural  
331 barriers in access to Covid-19 vaccination for PWD [12,72,76,88]. While PWD were described  
332 as more likely than people without a disability to endorse Covid-19 vaccination, they were more  
333 likely to report difficulties booking online vaccination appointments and locating and travelling  
334 to vaccination sites [12].

335 At the social and community level, having a trusted HCP or clinic exerted a positive  
336 influence on Covid-19 vaccination [12,57,76,88,91]. For example, among people living with  
337 multiple sclerosis (MS), MS-specialist HCPs and the National MS Society were deemed trusted  
338 sources: “well-positioned to provide accurate education about Covid-19 disease and vaccine  
339 considerations...specific to the MS population as well as their individual patients” [57,p.3].

340 At the individual level, perceived threat of Covid-19 was a positive correlate of Covid-19  
341 vaccination among PWD, including individuals with chronic diseases and multiple comorbidities  
342 [12,57,58,64,72,76,91]. Covid-19 vaccine-specific concerns included adverse effects, speed of  
343 vaccine development, vaccine safety, and efficacy [58,64,67,72,76,88,91]. In addition to “safety  
344 and efficacy...the top Covid-19 vaccination concerns”, apprehension arose around “the effect of

345 the vaccine on MS symptoms and implications for [immunosuppressive] DMT [disease-  
346 modifying therapy] use” [88, p.1078].

347

### 348 *Justice-involved people*

349 Four articles focused on Covid-19 vaccination among justice-involved (JI) individuals  
350 (i.e., currently or formerly convicted or incarcerated) [54,63,66,84]. At the structural level,  
351 medical mistrust and distrust of government exerted a negative impact on Covid-19 vaccination  
352 among individuals in detention facilities [54,63,84] “based on their interactions with law  
353 enforcement or the justice system or their experiences with institutional racism” [84, p.476]. A  
354 study with incarcerated women described “a direct correlation between trust in the  
355 pharmaceutical industry and willingness to receive the vaccine”: “I’ve watched too many people  
356 die because pharmaceuticals... So I don’t know. Pharmaceutical companies just see a lot of big  
357 money in there” [63, p.895]. One study described mitigation of structural-level barriers to Covid  
358 -19 vaccination through tailored vaccine education and “early access to vaccine through a  
359 dedicated federal allocation” for incarcerated individuals and facility staff [66,p.5889].

360 At the social and community level, family and community influence was associated with  
361 Covid-19 VH [54,63,66] among JI individuals in the absence of tailored public health  
362 messaging: “The probable low health and informational literacy of these women leave them  
363 vulnerable to influence from family and friends, many sharing and promoting disinformation and  
364 conspiracy theories frequently shared by homegrown anti-vaccine organizations” [63, p.895].  
365 Social proofing exerted a positive influence: “some people may have been encouraged to accept  
366 vaccination because they could see their peers being vaccinated” [54,66, p.5889].

367 At the individual level, all four studies reported low perceived risk of contracting Covid-

368 19 as a correlate of VH among JI people [54,63,66,84]. A study in correctional and detention  
369 facilities in 4 states reported that of participants (n=1823/5110) who would refuse Covid-19  
370 vaccination, 18.9% (n=344/1823) “did not perceive themselves to be at risk for Covid-19 or  
371 thought vaccination was unnecessary” [84, p.475]. Covid-19 vaccine-specific concerns arose  
372 around vaccine safety and efficacy [54,63,84], which was associated with “lack of access to  
373 reliable information” [54, p.375].

374

### 375 *People living with HIV/AIDS*

376 Two articles focused on factors impacting Covid-19 vaccination intentions among PLHA  
377 [70,80], with two additional sources providing PLHA-specific data [51,83]. At the structural  
378 level, medical mistrust and distrust of government among PLHA were associated with lower  
379 Covid-19 vaccination intentions [51,70,80]. A study with HIV-positive and predominantly  
380 sexual minority Black Americans (n=101) indicated that “The most prevalent general mistrust  
381 beliefs (endorsed by about half or more than half) concerned withholding information or a lack  
382 of honesty by the government,” which was correlated with VH [51, p.203]. A study with HIV-  
383 positive Black and Latinx Americans described unemployment being exacerbated by the  
384 pandemic, with negative impacts on access to healthcare and Covid-19 vaccination [70]. At the  
385 social and community level, the positive influence of personal HCPs as trusted sources of  
386 information on Covid-19 vaccination was reported [51,70,80]: “Lower hesitancy scores were  
387 present in participants who reported that they would get vaccinated if their provider  
388 recommended it” [80, p.98].

389 At the individual level, perceived threat was associated with Covid-19 vaccination  
390 intentions: “...HIV-positive men may have more concerns about the seriousness and perceived

391 impact of Covid-19 infection on their health” [80, 83, p.9]. Covid-19 vaccine-specific concerns  
392 arose around vaccine safety, adverse effects, and efficacy [51,70,80], with some PLHA  
393 concerned that their health condition may make Covid-19 vaccination unsafe [80].

394

### 395 ***People who use drugs***

396 Two studies focused on Covid-19 vaccination among people who use drugs (PWUD)  
397 [73,92], with one additional source providing disaggregated data on PWUD [64]. At the  
398 structural level, barriers to accessing healthcare and Covid-19 vaccines, as well as medical  
399 mistrust and distrust in government were associated with lower Covid-19 vaccination intentions  
400 [64,73]. One study noted vulnerability to misinformation among PWUD amid medical mistrust:  
401 “As a marginalized population, patients with illicit drug use are often detached from and mistrust  
402 the healthcare system—by extension, these patients may be more reliant on illegitimate  
403 information sources” [64, p.803]. At the individual level, mask wearing was associated with  
404 vaccine trust, both described as a function of accurate Covid-19 information [73]. Covid-19  
405 vaccine-specific factors arose around safety and efficacy concerns that may negatively impact  
406 uptake [73].

407

### 408 ***Immigrants and refugees***

409 One study focused on Covid-19 vaccination among immigrants and refugees [93], with  
410 one additional source providing disaggregated data [61]. At the structural level, barriers to  
411 healthcare and Covid-19 vaccine access were described as negatively impacting vaccination  
412 [61,93]. A study with Latinx immigrant families identified “fear of encountering law  
413 enforcement/immigration as barriers to access health care” [61, p.750]. Limited access to

414 information in one’s preferred language, lack of reliable information from trusted sources,  
415 constraints in access to the internet and digital technology, and lack of transportation and  
416 employment benefits (i.e., paid sick days) were identified as barriers to Covid-19 vaccination  
417 [93]. At the social and community level, family influence was demonstrated in a national online  
418 survey of refugees (n=435): among those who reported intention to receive a Covid-19 vaccine,  
419 nearly two-thirds (65.0%; n=199/306) indicated that it was motivated in part to protect their  
420 family members [93]. Covid-19 vaccine-specific concerns about vaccine safety, adverse effects,  
421 and efficacy were associated with VH, with two-thirds (71.3%; n=92/129) of refugees who  
422 reported no intention or being unsure of accepting Covid-19 vaccination indicating concerns  
423 about adverse effects [93].

424

### 425 *People experiencing homelessness*

426 One article focused on challenges to Covid-19 vaccination for people experiencing  
427 homelessness [71]. At the structural level, Covid-19 VH was described as a function of “a more  
428 general distrust of systems (e.g., health and homeless services) that are not designated to meet  
429 their needs” [71, p.6]. Trusting the information received from friends, family, and social media  
430 rather than “official news sources” was associated with greater Covid-19 VH [71]. At the  
431 individual level, general vaccine aversion and low Covid -19 risk perception, and vaccine-  
432 specific concerns about safety, adverse effects, and efficacy were associated with VH among  
433 people experiencing homelessness [71].

434

## 435 **Discussion**

436 This scoping review of Covid-19 vaccine hesitancy and broader underutilization of

437 Covid-19 vaccination provides evidence of multilevel determinants of delays or refusal of Covid-  
438 19 vaccination across marginalized populations in the U.S. Overall, a preponderance of  
439 structural-level factors were identified that impact Covid-19 vaccination across marginalized  
440 populations. Logistical and economic constraints including lack of transportation to distant  
441 locales, lack of paid sick days, lack of availability of vaccination at familiar/local community  
442 venues, and barriers in access due to being unemployed, unstably housed,  
443 uninsured/underinsured, and the digital divide (i.e., access to digital technology and the internet,  
444 and technical and financial ability to utilize it [94]) were compounded by lack of culturally and  
445 linguistically appropriate information and access to trusted HCPs. Collectively, these findings  
446 suggest that approaches to undervaccination among marginalized populations that focus  
447 predominantly on individual-level, psychological factors may fail to capture the breadth and  
448 impact of determinants of Covid-19 vaccination.

449       Importantly, we identified evidence for differential impacts of medical mistrust, as a  
450 structural factor [29], and trust in a personal HCP or clinic, as a social/community factor. The  
451 influence of medical mistrust reported with respect to government public health, healthcare  
452 systems, and the pharmaceutical industry, emerged across multiple marginalized populations—  
453 including African American, Latinx, LGBTQ+ populations, and their demographic  
454 intersections—attributed in part to historical discrimination and past unethical medical research  
455 and interventions, as well as present-day discrimination in healthcare and government  
456 institutions. Nevertheless, having a trusted HCP, particularly with shared race or ethnicity  
457 [26,51,69,70,74,82,85], or a familiar source of primary healthcare, mitigated Covid-19 VH—  
458 despite broader mistrust of healthcare systems and government public health. JI populations,  
459 PEH, and PWUD expressed medical mistrust due to generally negative experiences with

460 government and healthcare institutions. However, as in the case of JI populations, proactive  
461 interventions to promote tailored education along with policy decisions to prioritize Covid-19  
462 vaccination in prisons served to mitigate VH and promote vaccination [66].

463 Personal HCPs and usual care venues were widely reported to assuage concerns and  
464 reduce VH, indicating a crucial role for primary healthcare [95]. In this light, the absence of  
465 information from trusted sources tailored to address healthcare needs experienced as most  
466 relevant to one’s own community—reported among Black and Pilipino populations, PLHA and  
467 PWD—and the lack of availability of Covid-19 and vaccine information in one’s primary  
468 language (reported among Latinx, Asian, and immigrant/refugee populations) emerged as  
469 substantial missed opportunities to promote Covid-19 vaccination. Access to Covid-19  
470 vaccination from a known HCP or clinic may be particularly important for marginalized  
471 communities, who are more predisposed towards medical mistrust due to negative interactions  
472 with the healthcare system and other societal institutions, and more vulnerable to discrimination  
473 in healthcare [96,97].

474 Overall, the conflation of structural factors—documented in multifaceted barriers in  
475 access to Covid-19 vaccination and systemic mistrust of healthcare systems—with individual  
476 and social/community factors, such as perceived threat of Covid-19, perceived risk of  
477 transmission, general vaccine attitudes, endorsement from one’s personal HCP, and family  
478 influence, each of which may impact on “decisional conflict” more specifically aligned with VH  
479 [32], may fail to foster solutions that effectively address the identified problems [34,95,98].  
480 Moreover, the attribution of structural-level barriers to individual volition and deficits may  
481 exacerbate alienation and mistrust among populations already marginalized due to systemic  
482 discrimination, stigma, and adverse SDOH [96].

483           Interestingly, some of the same ostensible factors showed negative or positive  
484 associations with VH depending on the population and context. For example, family influence  
485 exerted a positive impact on Covid-19 vaccination among Latinx communities and  
486 immigrant/refugee populations through familial sharing of health information and desire to  
487 protect one’s family. However, among other populations, the context of medical mistrust and the  
488 virtual vacuum created by the absence of access to culturally tailored public health information  
489 rendered family influence a liability, resulting in promulgation of conspiracy theories and  
490 mistrust of Covid-19 vaccines among some African Americans [81], PEH [71], and JI persons  
491 [63]. These examples underscore the importance of approaching VH as a population-specific and  
492 context-dependent phenomenon [6,7]—in addition to disentangling the assessment of systemic  
493 factors from individual-level and social/community concerns [99]. Consequently, the same  
494 intervention applied to what might be understood as the same factor may exert opposite effects  
495 on Covid-19 VH across different populations.

496           Finally, facilitators of Covid-19 vaccination emerged despite constraints. For example,  
497 findings in common across PLHA and PWD—among whom one might reasonably expect  
498 heightened concerns about vaccination due to underlying comorbidities and potential interactions  
499 with routine medications—included the benefits of regular contact with a personal HCP or clinic;  
500 this promoted trust in the vaccine information received and confidence in the HCP’s ability to  
501 address population-specific concerns. Furthermore, intersectional strengths reported regarding  
502 Latinx immigrant and refugee populations included motivations to protect one’s community and  
503 cultural norms around familial sharing of health information, which served to mitigate VH.  
504 Beyond a deficit model, community assets and sociocultural facilitators may be leveraged [100]  
505 to support Covid-19 vaccination.

506 Findings from this scoping review should be understood in the context of limitations.  
507 First, as a scoping review, our objective was to map and synthesize evidence on Covid-19 VH  
508 and undervaccination among marginalized populations; we cannot draw causal conclusions about  
509 the associations identified, nor was our aim to quantify Covid-19 vaccination intentions or  
510 uptake, more apropos of meta-analysis. However, our scoping review methods reveal nuanced  
511 information through synthesis of quantitative and qualitative findings on population-specific  
512 barriers to Covid-19 vaccination and suggest important directions for future research. Second,  
513 additional populations to those included might be characterized by marginalization, although we  
514 based our focal populations on previous evidence and a priori criteria [42,43]. Third, while our  
515 initial search comprised studies from the U.S. and Canada, no studies were identified from  
516 Canada that met inclusion criteria during the specified time frame, possibly due to the later  
517 availability of Covid-19 vaccination to the general adult population [41]. Studies published after  
518 the time frame of our review might include additional populations, data, and study locales,  
519 although we purposely focused on the initial introduction of Covid-19 vaccines before  
520 subsequent booster doses and bivalent vaccines. Lastly, factors associated with VH and  
521 underutilization of monovalent and bivalent boosters may differ from those revealed for initial  
522 Covid-19 vaccination, although vaccine inequities remain [23].

523 In conclusion, we identified multilevel factors that influence Covid-19 VH and broader  
524 underutilization of Covid-19 vaccination, several of which may apply to other vaccinations. This  
525 scoping review suggests that distinguishing among individual and social/community factors that  
526 may fuel decisional ambivalence characteristic of Covid-19 VH—“a state of indecision and  
527 uncertainty about vaccination before a decision is made to act (or not act)” [35, p.58]—and  
528 factors attributable to systemic and structural barriers in access to vaccination and historically-

529 justified mistrust of healthcare institutions, government public health, and the pharmaceutical  
530 industry, may support evidence informed strategies to promote Covid-19 vaccination among  
531 marginalized communities. Nevertheless, distilling and applying lessons from Covid-19  
532 vaccination to effectively and equitably address VH and broader challenges in vaccine access  
533 may be contingent on resourcing and scaling up community partnerships and local health  
534 infrastructures [23,25,96,100], national population-specific public health initiatives to promote  
535 vaccination [101,102], and structural reforms beyond those traditionally associated with public  
536 health.
