## 20 ABSTRACT

21 **Background:** Vincristine poses a suspected additional risk factor for hearing loss among  
22 childhood cancer survivors (CCS) treated with platinum-based chemotherapy, yet evidence is  
23 scarce since no study reports vincristine doses. We examined the association of vincristine  
24 with hearing loss in a national cohort of CCS.

25 **Methods:** We included CCS registered in the Swiss Childhood Cancer Registry treated at  
26 age  $\leq 18$  years with platinum-based chemotherapy between 1990–2014. All participants in our  
27 retrospective cohort study had audiogram and treatment data from medical records. We  
28 identified CCS exposed to vincristine and calculated the total cumulative dose. We defined  
29 clinically relevant hearing loss as grade  $\geq 2$  using the International Society of Pediatric  
30 Oncology Boston Ototoxicity Scale at latest follow-up.

31 **Results:** Our study population included 270 CCS (43% female; median age at cancer  
32 diagnosis 6.8 years; interquartile range [IQR]: 2.1–11.7 years) with median age at audiogram  
33 13.5 years (IQR: 9.3–17.0 years). Vincristine exposure was associated with an increased risk  
34 of hearing loss in the multivariable logistic regression analysis (odds ratio [OR] 4.8; 95%  
35 confidence interval [CI]: 1.8–12.9). We found no evidence of dose-response relationship (OR  
36 1.0; 95% CI: 0.97–1.04) or effect modification from vincristine from other ototoxic  
37 treatments, such as type of platinum agent, cranial radiotherapy, and hematopoietic stem cell  
38 transplantation.

39 **Conclusion:** Vincristine is associated with a higher risk of hearing loss in CCS treated with  
40 platinum-based chemotherapy. We suggest future studies investigate the underlying  
41 mechanism and causality among CCS without exposure to other ototoxic cancer treatments.

42 **KEYWORDS:** vinca alkaloids, vincristine, hearing loss, ototoxicity, platinum compounds,  
43 cranial radiotherapy, childhood cancer survivors

#### 44 **1. Introduction**

45 Hearing loss is a side effect of platinum-based chemotherapy among children.[1] It is  
46 usually irreversible and impairs neurocognitive functioning of childhood cancer survivors  
47 (CCS).[2, 3] Several studies identified risk factors for platinum-induced hearing loss such as  
48 age at diagnosis, type of platinum agent, total cumulative dose of platinum, concomitant  
49 cranial radiotherapy (CRT), and hematopoietic stem cell transplantation (HSCT).[4-7]  
50 However, such factors insufficiently explain interindividual variation of platinum-induced  
51 hearing loss, possibly involving additional factors, such as vincristine.[4, 8, 9] Vincristine is  
52 known as neurotoxic and reported to cause central neuropathy with paralysis of the auditory  
53 nerve (cranial nerve VIII).[10, 11] In addition, vincristine-induced toxicity possibly affects  
54 the medial olivocochlear bundle and—to a lesser extent—the outer hair cells.[12]

55 Only two studies examined the role of vincristine in platinum-induced hearing loss,  
56 highlighting the need for further evidence.[4, 9] Both included vincristine as a co-variable in  
57 their analysis but did not further investigate the effect of the total cumulative dose of  
58 vincristine and whether there was effect modification between vincristine and other ototoxic  
59 cancer treatments. Therefore, we analyzed data from a nationwide cohort of CCS with  
60 treatment and audiogram data from medical records to 1) quantify the effect of vincristine on  
61 platinum-induced hearing loss; 2) test for interactions between vincristine and other ototoxic  
62 cancer treatments; and 3) determine a possible dose-response relationship of vincristine-  
63 induced ototoxicity.

## 64 2. Methods

### 65 2.1 Study population

66 We analyzed data from CCS treated with platinum-based chemotherapy between 1990–  
67 2014 in the nine specialized pediatric oncology clinics in Switzerland.[6] We included CCS 1)  
68 registered in the national and population-based Swiss Childhood Cancer Registry  
69 (SCCR),[13] 2) treated for cancer at age  $\leq 18$  years, 3) with no evidence of hearing loss  
70 before start of cancer treatment in their medical records, and 4) available audiogram after  
71 completing platinum-based chemotherapy.[6] Further details about identifying eligible CCS  
72 and data collection are published elsewhere.[6, 14] The Ethics Committee of the Canton of  
73 Bern approved the SCCR and the Swiss Childhood Cancer Survivor Study (KEK-BE:  
74 166/2014; 2021-01462).[15]

### 75 2.2 Study procedure

76 We collected clinical information on cancer diagnosis and treatment from medical records  
77 and the SCCR in 2015.[6, 14] We extracted clinical variables, including sex (female, male);  
78 cancer diagnosis according to the International Classification of Childhood Cancer (3<sup>rd</sup>  
79 edition)[16]; age at cancer diagnosis ( $< 5$ , 5–9, and 10–18 years); period of cancer diagnosis  
80 (1990–1995, 1996–2001, 2002–2007, and 2008–2014); type and total cumulative dose  
81 ( $\text{mg}/\text{m}^2$ ) of platinum agents (cisplatin, carboplatin); CRT (yes, no); and HSCT (yes, no).  
82 During initial data collection in 2015, no treatment information about vincristine exposure  
83 was collected. We went through all medical records and treatment protocols again in 2022 and  
84 calculated vincristine exposure and total cumulative vincristine dose ( $\text{mg}/\text{m}^2$ ) as treated or—  
85 when unavailable—based on treatment protocol.

## 86 2.3 Measurement of hearing loss

87 We determined hearing loss at latest follow-up after completion of platinum-based  
88 chemotherapy. We evaluated audiograms with the classification system of the International  
89 Society of Pediatric Oncology (SIOP) Boston Ototoxicity Scale.[17] Based on the approach of  
90 previous studies, we defined clinically relevant hearing loss (yes, no) as SIOP-Boston grade  $\geq$   
91 2.[4, 6] In cases of asymmetric hearing, we took the most affected ear as the reference for  
92 grading. Further details on the evaluation of the audiograms were previously published.[6]

## 93 2.4 Statistical analysis

94 First, we compared the prevalence of clinically relevant hearing loss overall and stratified  
95 by type of platinum-based chemotherapy between CCS with and without vincristine exposure.  
96 We fitted univariable logistic regression models including sex, age at audiogram, age at  
97 cancer diagnosis, period of cancer diagnosis, type of platinum-based chemotherapy, exposure  
98 to vincristine, concomitant CRT, and HSCT as exposures and clinically relevant hearing loss  
99 (yes, no) as outcome.[6] The multivariable regressions included a priori sex, age at most  
100 recent audiogram, age at cancer diagnosis, and all other clinical characteristics previously  
101 associated with hearing loss at  $P < 0.05$  in the univariable models. To examine effect  
102 modification of other ototoxic treatments, we included interaction terms between vincristine  
103 exposure and type of platinum-based chemotherapy, CRT, and HSCT.[4, 18, 19] We also  
104 included the total cumulative dose of cisplatin, carboplatin, and vincristine as a continuous  
105 variable in a sub-analysis, which included only CCS who received vincristine, to determine a  
106 possible dose-response relationship. We excluded survivors with missing values for the

107 cumulative dose of vincristine or platinum-based chemotherapy from the regression analysis.

108 We calculated global *P*-values using likelihood-ratio tests (LRT).

109 We performed a sensitivity analysis to control for additional ototoxic factors, such as brain  
110 surgeries or cerebrospinal fluid shunts, associated with central nervous system (CNS) tumors  
111 diagnosis.[1, 20] We included CNS tumor diagnosis (yes, no) as a co-variable in our  
112 multivariable regression model.

113 We used Stata version 16.1 (StataCorp LP, Austin, TX, USA) for all analyses.

## 114 3. Results

### 115 3.1 Characteristics of study population

116 We included 270 CCS with a median age at cancer diagnosis of 6.8 years (interquartile  
117 range [IQR]: 2.1–11.7 years) in our analysis (Table 1). A detailed flow-diagram of the study  
118 population was published elsewhere.[6] Median time from cancer diagnosis to most recent  
119 audiogram was 5 years (IQR 2.5–8.1 years). The most common cancer diagnoses were CNS  
120 tumors (n = 104; 39%). Over half (n = 145; 54%) received vincristine with a median total  
121 cumulative dose of 23 mg/m<sup>2</sup> (IQR 10.1–40.9 mg/m<sup>2</sup>) (Supplement Figure A.1). CCS  
122 previously treated with vincristine were younger at cancer diagnosis, more likely survivors of  
123 CNS tumors or neuroblastoma, and received more often carboplatin, CRT, and HSCT than  
124 CCS without vincristine exposure.

### 125 3.2 Role of vincristine in platinum-induced hearing loss

126 Of the included CCS treated with vincristine, 49% (95% CI: 41-57) had hearing loss  
127 compared with 22% (95% CI: 15-30) of CCS not treated with vincristine ( $p < 0.001$ ) (Figure  
128 1). Stratified by type of platinum-based chemotherapy, we saw the largest difference in  
129 prevalence of hearing loss between CCS with and without vincristine exposure among those  
130 treated with only cisplatin (68% vs. 21%).

131 Exposure to vincristine was associated with a higher risk for hearing loss in the univariable  
132 (odds ratio [OR] 3.5, 95% CI: 2.0–6.0) and multivariable (OR 4.8, 95% CI: 1.8–12.9) logistic  
133 regression analyses (Table 2). Using interaction terms, we found no evidence for effect  
134 modification between exposure to vincristine and type of platinum-based chemotherapy,

135 CRT, and HSCT (all  $P > 0.05$ ) (Table 3). In a sub-analysis including only CCS with vincristine  
136 exposure, we found no evidence for a linear effect of total cumulative vincristine dose on the  
137 risk of hearing loss (OR 1.0, 95% CI: 0.97–1.04) (Table 2) (Supplement Figure A.1).

138 In our sensitivity analysis, diagnosis with a CNS tumor (yes, no) was not associated with  
139 an increased risk for hearing loss in the multivariable regression (OR 0.8, 95% CI: 0.2–2.7)  
140 (Supplement Table A.1). The effect size of vincristine (yes, no) did not change compared with  
141 the model without adjustment for CNS tumor diagnosis (OR 5.3, 95% CI: 1.7–17.0 vs. OR  
142 4.8, 95% CI: 1.8–12.9).

#### 143 **4. Discussion**

144 In our nationwide cohort study of CCS treated with platinum-based chemotherapy, we found  
145 the prevalence of platinum-induced hearing loss higher among CCS with additional  
146 vincristine than of CCS without vincristine exposure. Vincristine exposure increased the risk  
147 of hearing loss fivefold when adjusting for clinical characteristics. However, we found no  
148 evidence of a dose-response relationship of cumulative vincristine dose and the risk for  
149 hearing loss, or evidence of effect modification by other ototoxic cancer treatments.

150 Our study is strengthened from analyzing the ototoxicity of vincristine in a large cohort of  
151 CCS in terms of overall exposure and considering the total cumulative vincristine dose and  
152 potential interactions with other ototoxic cancer treatments. Further strengths include the  
153 well-described cohort with clinical data on hearing function, cancer diagnosis, and platinum-  
154 based chemotherapy available. However, we cannot conclude whether vincristine is ototoxic  
155 independently or only in combination with platinum agents because all included CCS were  
156 treated with platinum-based chemotherapy. Furthermore, we had no data on brain surgery or

157 cerebrospinal fluid shunts among survivors of CNS tumors, which have been associated with  
158 an increased risk of hearing loss in other studies.[1, 20, 21] Because 70% of CCS in our  
159 cohort who received vincristine were diagnosed with CNS tumors and most patients with  
160 CNS tumors were exposed to vincristine (97%), we cannot exclude that part of the association  
161 of vincristine with hearing loss as possibly explained by other factors associated with the  
162 diagnosis of CNS tumors or other concomitant treatments. However, in our sensitivity  
163 analysis, CNS tumor diagnosis was not associated with an increased risk of hearing loss and  
164 the effect of vincristine remained unchanged after controlling for CNS tumor diagnosis. We  
165 also lack data on use of concomitant ototoxic drugs such as aminoglycoside antibiotics and on  
166 prophylactic administration of sodium thiosulfate.[1, 22] However, sodium thiosulfate was  
167 only recently been approved in the United States for clinical use; it is not yet approved in  
168 Switzerland.[23] Another limitation is the retrospective study design and the use of non-  
169 standardized routine data from different clinics.

170 Ototoxicity of vincristine was reported mainly in case studies of adult patients with cancer  
171 and in two recent cohort studies involving CCS.[4, 9, 11, 24-27] Moke and colleagues  
172 examined hearing loss in a large multi-center cohort of 1,481 children, adolescents, and young  
173 adults treated with cisplatin.[4] They also collected data on vincristine exposure and reported  
174 that vincristine (yes, no) increased the risk for cisplatin-induced hearing loss by a factor of  
175 four (OR 3.6) at latest follow-up,[4] which is consistent with our estimate (OR 4.8). However,  
176 a direct comparison must be made with caution because Moke and colleagues also included  
177 adults in their analysis and the regression models differed in terms of selected co-variables. In  
178 another cohort study of 368 pediatric patients with cancer, Meijer and colleagues  
179 demonstrated vincristine exposure (hazard ratio 2.9) was an important determinant for the

180 cumulative incidence of cisplatin-induced hearing loss.[9] Neither of the two cohort studies  
181 included data on the cumulative dose of vincristine.[4, 9]

182 We did not observe an effect from higher cumulative doses of vincristine on the risk of  
183 hearing loss, yet we had no data on administration method, timing of administration with  
184 other drugs (particularly platinum agents), pharmacokinetics, drug-drug interactions with  
185 azole antifungals, and genetic factors possibly affecting total exposure and toxicity of  
186 vincristine.[28-31] Two prospective studies with small sample sizes ( $N \leq 23$ ) examined  
187 ototoxicity of vincristine and included dose information.[12, 32] Lugassy and colleagues  
188 enrolled adult patients with cancer ( $N=23$ ) in their study and did not observe any deleterious  
189 effects from vincristine on hearing among patients with moderate dose exposure (mean total  
190 dose of 12 mg).[32] One patient on high-dose vincristine (total dose of 24 mg) developed  
191 sensorineural hearing loss during the observation period.[32] Riga and colleagues enrolled  
192 pediatric patients diagnosed with leukemia in their study ( $N=15$ ) who had been treated  
193 according to the Berlin-Frankfurt-Muenster-95 (BMF-95) protocol. In their study, exposure to  
194 low and moderate doses of vincristine ( $\leq 1.5 \text{ mg/m}^2$  per dose) did not result in any abnormal  
195 changes ( $\geq 15 \text{ dB}$ ) in mean hearing thresholds levels measured by pure tone audiometry at  
196 latest follow-up.[12] But they found abnormalities in transient evoked otoacoustic emissions  
197 (TEOAE) and a decrease in contralateral suppression after three cycles of vincristine  
198 administration, indicating a measurable neurotoxic effect of vincristine on outer hair cells and  
199 the medial olivocochlear bundle.[12] However, the study's short observation period of 22 days  
200 does not allow prediction of the reversibility of observed effects or subsequent detection of  
201 hearing loss.[12]

## 202 5. Conclusion

203 Our results support emerging evidence for an increased risk of platinum-induced hearing  
204 loss with concomitant vincristine administration.[4, 9] Interindividual variability in hearing  
205 loss after platinum-based chemotherapy is large and not yet fully understood.[8], which  
206 emphasizes the importance of identifying additional risk factors for hearing loss among CCS,  
207 such as the neurotoxic treatment vincristine. However, we suggest including TEOAE  
208 measurements in further studies to better understand the mechanism and clinical course of  
209 vincristine-induced neurotoxicity in the medial olivocochlear bundle and its influence on  
210 platinum-induced hearing loss. In addition, we suggest investigating causality of vincristine  
211 and hearing loss among CCS without platinum-based chemotherapy or CRT to determine  
212 whether vincristine causes permanent hearing loss even without established ototoxic cancer  
213 treatments and whether genetic factors possibly play a role.

214 **Clinical trial registration**

215 Not applicable.

216 **Funding source**

217 This study was supported by the Swiss Cancer League (HSR-4951-11-2019), the  
218 CANSEARCH Foundation (<https://cansearch.ch/>), and the European Union's Seventh  
219 Framework Program for research, technological development and demonstration under grant  
220 agreement no. 602030. The EU Commission takes no responsibility for any use made of the  
221 information set out. Further funding comes from Swiss Cancer Research (KLS/KFS-4825-01-  
222 2019, KFS-5027-02-2020) and Kinderkrebshilfe Schweiz  
223 (<https://www.kinderkrebshilfe.ch/de>).

Yes	6	(3)	20	(20)	7.1 (2.7–18.4)		5.2 (1.4–19.4)		12.1 (1.7–83.6)	

Abbreviations: CI, confidence interval; HSCT, hematopoietic stem cell transplantation; n.a., not applicable; OR, odds ratio; SIOP, International Society of Pediatric Oncology.

<sup>a</sup>Factors associated with hearing loss at  $P < 0.05$  were included in the multivariable analyses. Sex, age at audiogram, and age at cancer diagnosis were included in the multivariable model independent of the strength of the association in the respective univariable model.

<sup>b</sup>Main analysis including vincristine (yes, no) and exposure to platinum-based chemotherapy (cisplatin, carboplatin, both platinum agents) as categorical variables (N=270).

<sup>c</sup>Sub-analysis including only childhood cancer survivors (CCS) exposed to vincristine with total cumulative doses of chemotherapy as continuous variables (N=139). CCS with missing dose information (n=6) were excluded from analysis.

<sup>d</sup>Odds ratio from univariable and multivariable logistic regression models: OR  $< 1$  indicates that SIOP-Boston grade  $\leq 1$  is more likely. OR  $> 1$  indicates that SIOP-Boston grade  $\geq 2$  is more likely.

<sup>e</sup>Global  $P$ -value calculated from likelihood-ratio test.

**TABLE 3** Interactions between vincristine and other ototoxic cancer treatments

	Multivariable <sup>a</sup>	
	OR <sup>b</sup> (95%-CI)	<i>P</i> -value <sup>c</sup>
<b>Model 1</b>		
<i>Test for interaction between platinum-based chemotherapy and vincristine</i>		
Carboplatin	<i>Reference</i>	0.274
Cisplatin × vincristine exposure	2.8 (0.2–35.2)	
Both platinum agents × vincristine exposure	0.5 (0.03–11.0)	
<b>Model 2</b>		
<i>Test for interaction between CRT and vincristine</i>		
No CRT	<i>Reference</i>	0.200
CRT × vincristine exposure	0.3 (0.04–2.0)	
<b>Model 3</b>		
<i>Test for interaction between HSCT and vincristine</i>		
No HSCT	<i>Reference</i>	0.354
HSCT × vincristine exposure	4.4 (0.18–105.8)	

Abbreviations: CI, confidence interval; CRT, cranial radiotherapy; HSCT, hematopoietic stem cell transplantation; OR, odds ratio.

<sup>a</sup>Each interaction between vincristine and the variables platinum-based chemotherapy, CRT, or HSCT was analyzed in a separate multivariable model (Models 1–3) (N=270). Each model was adjusted for sex, age at audiogram, age at diagnosis, period of diagnosis, other ototoxic cancer treatments (i.e. platinum-based chemotherapy, CRT, or HSCT).

<sup>b</sup>Odds ratio from univariable and multivariable logistic regression models: OR < 1 indicates that SIOP-Boston grade ≤ 1 is more likely. OR > 1 indicates that SIOP-Boston grade ≥ 2 is more likely.

<sup>c</sup>Global *P*-value calculated from likelihood-ratio test.

**FIGURE 1** Comparison of prevalence of clinically relevant hearing loss between childhood cancer survivors with and without vincristine exposure (N=270). Prevalence is shown for the overall cohort and stratified by type of platinum-based chemotherapy.
